It has been customary to denounce Origen and the Alexandrian school for their indulgence in allegory and to contrast with them most favorably the next great school of exegetes at Antioch. The most distinguished names here were those of Lucian, Diodorus, Theodore, Theodoret, and Chrysostom. We are told that these men were literalists rather than allegorists. They held rigidly to the historical and grammatical sense, and it is but natural that the historical and grammatical critics of the nineteenth century should applaud their opposition to the allegorical flights of the Alexandrians. However, it is well for us to remember that this school had its dangers and faults as well as the Alexandrian. Its literalism resulted in a rationalism which was like a dry rot in the church. Historically, it led directly to Arianism, which threatened to cut the tap-root of the Christian faith; and against this the orthodox exegesis of Athanasius the Alexandrian, proved to be the only safeguard of the church at the last. Its tendency was to narrowness, rather than to richness. What it gained in straitness, it lost in breadth. However, among all the Greek fathers, Chrysostom will rank next to Origen in uniting the best characteristics of both schools. "Through a rich inward experience he lived into an understanding of the Holy Scriptures; and a prudent method of interpretation, on logical and grammatical principles, kept him in the right track in deriving the spirit from the letter of the sacred volume" (Neander, 'History of the Christian Religion and Church,' II. p. 693). Origen and Chrysostom had no worthy successors in the next millennium of church history. Jerome has been called the Origen of the Western Church, but he was too hasty in composition, too much influenced by his personal prejudice, and too vacillating and uncertain in his own opinions to deserve this name as an exegete. His services in other directions were invaluable. He was the greatest scholar in the West as Origen had been the greatest scholar in the East; but he lacked the depth of character, the consistency of principle, and the consequent spiritual intuition of that greatest master in the early church.

Augustine has exerted a wider influence upon the Christian Church than any other of the church fathers. He was the chief authority through the whole of the mediæval age. Martin Luther was an Augustinian monk at the time of his conversion; and he and Melanchthon and Calvin and Bucer all built upon the foundations which Augustine had laid down. The works of the great Latin father have been read and reverenced by Protestant and Roman Catholic alike, and it is only in our day that serious question has arisen as to his right to continued supremacy. In the present reaction from the theology of the Latin fathers to the older and purer theology of the Greek fathers, it is in the field of scholarly exegesis that the inferiority of Augustine becomes most apparent. He was not even the equal of Jerome in scholarship. He knew no Hebrew. He was very deficient in his knowledge of the Greek. He preferred a translation to the original text. He was continually making mistakes as to the meaning of words. He had all the defects of his predecessors, without their excuse for them. The Alexandrians had been driven into the use of allegory to harmonize the Gospel teaching with the truth of Greek philosophy and to command the hearing and respect of their Jewish contemporaries. But Augustine was an allegorist of the allegorists, when no necessity was laid upon him and when allegory had degenerated into mere imaginative ingenuities. Augustine had genius and a genuine Christian experience and consequently flashes of illuminative interpretation are found in his books, but these cannot compensate for the lack of the critical faculty and a sound basis of linguistic scholarship in exegesis. "Spiritual insight, though a far diviner gift than the critical faculty, will not supply its place. In this faculty Augustine was wanting, and owing to this defect, as a continuous expositor he is disappointing" (Lightfoot, 'Commentary on Galatians,' p. 233). His total influence has been an immeasurable bane to Christendom. He was chiefly responsible for subordinating exegesis to ecclesiastical authority. He said, "For my part, I should not believe the gospel except as moved by the authority of the Catholic Church" ('Ep. c. Manich.,' ch. 5. sect. 6). He declared, "Now Scripture asserts nothing but the Catholic faith" ('De Doctr. Christ.' III. ch. 10. sect. 15), and he bent his exegesis to make good that declaration. He fastened upon the Christian Church the dogmas which have been the chief hindrances to its progress for 1,400 years: "the exaggerated doctrine of total human depravity," the guilt of innocent infancy, arbitrary election involving a practical denial of the freedom of the human will, atonement by quantitative equivalence in suffering, the subtle systematization of divine counsels and schemes, the imperious necessity of sacerdotalism and sacramentarianism, intolerance of opinion contrary to churchly authority, even when based upon an earnest and intelligent study of the revealed Word. Following his lead the Church has floundered for centuries through sloughs of despond and has almost forgotten the broader horizon and the fresher air of the high table-lands of the earlier theology. Among the Greek fathers no one of these questions which have afflicted our Latinized christianity found an atmosphere congenial enough in which to thrive. We owe much to Augustine, but it is hard for us to believe that his good influence can begin to equal his evil influence upon the Christian Church. His is the last great name among the church fathers. For a thousand years little or no progress was made in the interpretation of the Scriptures.

The Schoolmen contented themselves for the most part with copying and compiling the work of their predecessors in this field. It became a proverb among them, Si Augustinus adest sufficit ipse tibi. One of them stated plainly that no interpretation of Scripture must be accepted which ran counter to the authority of the Church, "however much such a sense may be in conformity with the literal meaning. Indeed that ought not to be called the literal sense which is repugnant to ecclesiastical authority" (Paulus of Burgos, 'Prol. in Additiones'). Even Gerson declares, "The literal sense must be judged according as the Church has determined" (Propp. de sens. lit. 3). With no independence of thought and with no fresh scholarship the schoolmen added no new principle of exegesis in a thousand years of commentary writing. They were expending their energies upon subtle and futile speculations. They composed great folios which aimed at nothing original and arrived nowhere in particular. They labored hard in a treadmill. They were weakest in exegesis. Only two or three of them knew any Hebrew, and the most of them knew very little if any Greek. They were unoriginal, uncourageous, uncertain, uninformed. They had a wrong notion of the Church and a wrong conception of inspiration, and it naturally followed that they had a wrong method of exegesis. They had their merits too, but not as exegetes.

With the Protestant Reformation we come to a new era in Scriptural exegesis. Coleridge said of the Reformers, "The least of them was not inferior to Augustine and worth a brigade of Cyprians, Firmilians, and the like" ('Remains,' III. p. 276). Calvin sweepingly asserts, "Modesty will not allow me to speak of ourselves as fact would justify; and yet I will most truly declare that we have thrown more light upon the Scriptures than all the doctors who have appeared under the Papacy since its commencement. This praise even they themselves dare not deny us" ('Antid. in Conc. Trid.,' Sess. IV). The Bible seemed like a fresh discovery to the Church of that day. For the first time it became the property of the common people; and the printing press made it possible for it to become a common possession. It had been locked up in the Latin tongue and was supposed to be the peculiar property of the priests. Translations now made it accessible to all and the Protestant preachers constantly appealed to its authority in their opposition to the usurpations and the abuses of the hierarchy. That necessitated a renewed study of the sacred text on both sides. It soon became impossible for a man to be a doctor of divinity for eight years, as Carolstadt confessed that he had been, before he had read his New Testament. The Protestants delighted to circulate such stories as that of Sixtus of Amana concerning Albert, archbishop of Mayence, who read a few pages in the New Testament and then put it down, saying, "I know not what book this is, I only see that all things contained in it are hostile to us" ('Antibarb. Bibl.' II. 7). The churchmen and schoolmen had always based their doctrinal systems upon the Bible, but the stereotyped interpretation of the Scriptures had come to claim the authority of the Scriptures themselves. John Nathin said to Martin Luther in the convent at Erfurt, "Brother Martin, let the Bible alone; read the old teachers: they give you the whole marrow of the Bible; reading the Bible simply breeds unrest" (Lindsay, 'History of the Reformation in Germany,' p. 200). Heresbach, the friend of Erasmus, heard it said that the study of the original Greek was the prolific source of all heresies, while the study of Hebrew turned men into Jews at once. (D'Aubigne, I. ch. 3). It was deemed dangerous for the layman to attempt to understand the Scripture for himself; it was his duty to accept the interpretation of the book by the Church. It was at this point that the protest was made; and all the Reformers insisted that the Bible ought to be open to every man and that the Spirit of God would help every man to a safe and sufficient understanding of its contents. Luther came to take the position that no external authority could decide what was Scripture or what was the meaning of Scripture. He said, "How can we know what is God's Word and what is true or false? . . . . Who decides me there? No man, but only the truth which is so perfectly certain that nobody can deny it" (Dods, 'The Bible, Its Origin and Nature,' pp. 38-40). Calvin said, "Scripture is self-authenticated, carrying with it its own evidence. . . . It obtains the credit which it deserves with us by the testimony of the Spirit" ('Institutio.' I. 7; 5). Over against this position may be put the words of Lacordaire, "What kind of a religion is that which saves men by aid of a book? God has given the book, but He has not guaranteed your private interpretation of it. . . If there be a true religion on earth, it must be of the most serene and unmistakable authority" (cf. Lindsay. op. cit., p. 457). That authority is not, according to Lacordaire, found in private judgment but in the infallible decree of Pope or Councils. Such was the issue drawn by the Reformation, both parties claiming the authority of the Scriptures, the one as interpreted by the Church for all, and the other as interpreted by the Spirit to each man. It was equally incumbent upon all concerned to show that their interpretation was the true one. This battle over the Book led to such searching of the Scriptures as had not been seen in the Church in any period of its history.

The way was opened for an intelligent discussion of the Scripture text largely by the labors of Erasmus of Rotterdam. His edition of the Greek Testament became the standard text among the reformers. His translations annotations, and paraphrases entitle him to high rank as an exegete. He was independent in judgment, characterized by good sense, and a philologist without a peer. His aim was to make the meaning of the Word perfectly clear to all. He said, "I do not see why the unlearned are to be kept away, especially from the evangelical writings, which were proclaimed alike to learned and unlearned, equally to Greeks and Scythians, as much for slaves as for the free, at the same time to men and to women, not less to peasants than to kings" ('Praef. in Paraph. in Matt.'). Erasmus still clung to the mystical or allegorical interpretation of certain Scriptures and thought that the Holy Spirit had intended that some words should carry multiple meanings. It was Martin Luther who broke finally and conclusively with this ancient error. He deserves highest honor as an exegete as well as a reformer by the enunciation of this principle, "Each passage has one clear, definite, and true sense of its own. All others are but doubtful and uncertain opinions." He added, "The literal sense of Scripture alone is the whole essence of faith and of Christian theology. . . . Allegories are empty speculations. . . . An interpreter must as much as possible avoid allegory that he may not wander into idle dreams. . . . To allegorize is to juggle with Scripture. . . . If we wish to handle Scripture aright, our one effort will be to attain *unum, simplicem, germanum, et certum sensum literalem*" ('Commentary on Genesis'). Unlike Jerome and so many others who had recognized these truths before him, he is true to these principles in his own exegesis. He published 'Notes' on many portions of the Scripture, and a complete 'Commentary on Galatians.' His exegetical works were published in a score or more of volumes in both Latin and German, and were of paramount influence in introducing better methods of exegesis in the Reformed churches. Melanchthon, Bucer, Zwingli, Beza, and many others did notable work in exegesis in the Reformation period; but their books are for the most part unread to-day. The greatest exegete among the reformers was John Calvin. He wrote complete commentaries on nearly the whole of the Bible. The single exception in the New Testament was the book of the Apocalypse; and Judges, Ruth, Kings, Esther, Ezra, Nehemiah, Proverbs, Ecclesiastes, and Song of Solomon were the only books left untouched in the Old Testament. His commentary on the Psalms was justly celebrated for its religious insight; and in the Pauline epistles and the book of Acts he is at his best in the New Testament. He wrote to his friend Grynæus in 1539, "We were both of this mind, that the principal point of an interpreter did consist in a plain briefness. . . . We wished that there might be some one who gave his diligence not to trouble those who are desirous of learning with long commentaries" ('Praef. in Rom.'). This suggests one chief excellence of Calvin's exegetical work. It is clear and concise and not loaded down with references to a host of other authorities. Calvin has the learning necessary for his task, but he makes no needless display of it. He uses it simply to present plainly the meaning of the text. He was honest and independent in his comment, intelligent in his method, and comparatively free from the worst faults of all his predecessors in this line. He never agreed with Luther as to the adequacy of the private judgment; and yet he was a persecutor of those who did not agree with his own views. The prejudices of his peculiar theology appear throughout his commentaries, and the repudiation of his conception of the decree as the central idea of Christianity has gone far to detract from his use and usefulness in the America of the 20th century. However he is still worth consulting for his good sense in most things and his good style in all.

It seemed a necessity of the age that all Christians should be dogmatists, and Protestant dogmatism soon became as deadly an influence in the field of exegesis as Roman Catholic tradition had ever been. The successors of the great Reformers were like the schoolmen who succeeded the great Fathers of the early Church. They were subservient to authority and fettered by dogma; and in the 17th and 18th centuries very few exegetes appeared whose works are read to-day. The scholarship of the elder Lightfoot is valued. The practical comments of Robert Leighton on First Peter are still enjoyed. John Owen's Exercitations on the Epistle to the Hebrews is a monument of erudition and pious reflection; but, like Caryl on Job, it is too voluminous to hold attention in this modern age. Robert Hall said of Owen, "He always takes for granted what he ought to prove, while he is always proving what he ought to take for granted; and after a long digression, he concludes very properly with, This is not our concernment; and returns to enter upon something still farther from the point." Adam Clarke added, "To me he is one of the most unsatisfactory of writers. His sense and meaning he drowns in a world of words. He cannot condense his meaning, and never comes to the point, but by the most intolerable circumlocution" (Etheridge, 'Life of Adam Clarke,' pp. 317-18). He may stand as probably the last example the world will ever see of such intolerable prolixity. Arminius and Grotius introduced the reaction from Calvinistic and Lutheran and Augustinian exegesis, which has been gathering force ever since and which has about come to its triumph in America. Cocceius and Vitringa in their opposition to scholasticism and dogmatical bias furnished a series of commentaries with many excellent qualities, but reverting too far in the direction of the mystical or allegorical interpretation. Bengel's Gnomon is a model of brevity and learning in exegesis. Philip Schaff calls it "a marvel of *multum in parvo.*" Henry, Scott, and Adam Clarke wrote devotional commentaries which are still in use. Ernesti has been regarded as the founder of a new exegetical school, attempting to hold the *via media* between the allegorists and the dogmatists. His exegesis was predominantly grammatical. Semler, pietist and rationalist, introduced the historic method of exegesis, and prepared the way for the unparalleled exegetical activity of the 19th century. The most dominant influence in the 19th century in the whole field of theology was that of Schleiermacher. He was the founder of what has been called the psychological school of exegesis. He was both rationalistic and supernaturalistic in his interpretation of the Scriptures. He appealed to opposing classes and did much to bring all Germany back to a central emphasis upon the person and teaching and influence of Christ. In Germany and, through Coleridge and Maurice, in England and America his spirit and methods have been fruitful of much good in Biblical study. "Church history offers no parallel to him since the days of Origen" (Farrar, 'History of Free Thought,' p. 244). "He was the Plato and Origen of Germany in the 19th century" (Philip Schaff). He based his religion upon faith and feeling, and he made the Christian consciousness and personal experience the guiding lights of his Scriptural interpretation. He claimed a Divine compulsion in his teaching and spoke and wrote with prophetic fervor and authority. He said, "Divinely swayed by an irresistible necessity within me, I feel myself compelled to speak. . . Nor is it done from any caprice or accident. Rather . . . it is a divine call" ('Reden über die Religion,' I). His personal magnetism and pronounced genius, his eloquence and earnestness, the genuineness of his Christian experience, the remarkable breadth of his vision and thought, and the intensity of his spiritual zeal gave him a most extraordinary influence upon his own and succeeding generations. He vindicated the right of Christian experience to an equal hearing with the results of any purely scientific research. His spirit pervades the Christian world to-day and will maintain its permanent place in Christian thought. De Wette was the greatest exegete among the disciples of Schleiermacher. His work represents prodigious learning and "perfect loyalty in the search for truth" (Godet). He expresses himself clearly, but does not always come to a desirably definite conclusion. Credner occupied practically the same standpoint.

The year 1835 marked a new era in all scientific Bible study (Pfleiderer, 'Development of Theology,' p. 209). In that year Strauss published his 'Life of Jesus,' Baur, his work on the 'Pastoral Epistles,' and Vatke his 'History of the Religion of the Old Testament.' Each of these books may be regarded as epoch-making.

Eichhorn had reduced the rationalistic treatment of the Scriptures to a scientific system. Strauss was the first to put this rationalism into concrete and popular form. Baur was the founder of the Tübingen or Tendency school, which probably represented in Germany the greatest theological movement of the century. Baur endeavored to bring all his exegesis to the bar of historical investigation. He examined all traditional exegesis critically and subjected the New Testament books to a more thoroughgoing analysis than they had ever known. He emphasized the theological standpoint of each writer, and he thought he detected an irreconcilable antagonism between the Pauline and the Petrine wings of the Christian Church. He stimulated Bible study to an astonishing degree. His personal power was manifest in the remarkable group of disciples he gathered about him. Among these we may mention Zeller, Schwegler, Hilgenfeld, Holsten, Pfleiderer, and Volkmar. The entire movement inaugurated by Baur has been characterized by comprehensive and accurate scholarship, the value of which has been somewhat impaired by the critical presuppositions upon which it was based. Strauss came over into this school in the second edition of his 'Life of Jesus.' Ritschl began his career in it, but later swung clear of it and became the founder of a distinct school of thought, to which Harnack, Jülicher, Kaftan, Hermann, and Von Soden adhere.

Ritschl claimed to repudiate all metaphysical presuppositions and to found his system on the religious consciousness alone. He believed that the primitive faith sprang from the person and word of Jesus, with no philosophical alloy in the beginning. He held that experience limits the domain of knowledge. The Scriptures are sufficient in themselves to reveal the spiritual and moral worth of the kingdom of God, whose end is realized in love. Dogmatics and ethics unite in the higher synthesis of the revelation of the New Testament. Frank was the most determined opponent of Ritschlianism in Germany. He pointed out the lack of a true and deep conception of sin in this system of thought, and its consequently inadequate notion of atonement and conversion; and he claimed that, instead of rejecting metaphysics, the whole system was based on a highly developed but false and contradictory metaphysics of its own.

Vatke in 1835 outlined the revolution which has since taken place in the conception of Old Testament history. His book, however, was overloaded with philosophical terminology and met with no general appreciation and soon seemed to be forgotten. Reuss lectured along the same lines at Strassburg; and two of his pupils, Graf and Wellhausen, published the new hypothesis of the development of Old Testament ritual and literature. It was Vatke's theory brought to life again, and it has exercised increasing influence upon the exegesis of all the Old Testament books for the last half century. The prophets have come into new prominence as a result of this study. They are recognized as the founders of the Hebrew religion. The Law in its present form was of later growth in the Jewish Church. The Pentateuch has been resolved into a number of documents. Deuteronomy is believed to belong to the times of Josiah. Isaiah and other prophetic books are shown to be of multiple authorship. The Psalms come last in the Hebrew sacred literature. Stade, Budde, Smend, Schultz and others have represented this school of thought.

Germany has been the great battle-ground of the Higher Criticism through the last century; and the exegetes have enrolled themselves among the critical and the traditional, the more radical and the more conservative camps. Neander the champion of spirituality, Hengstenberg the bulwark of orthodoxy, Delitzsch the pre-eminent scholar did valiant service for what they deemed the traditional truth. Just before his death Delitzsch seemed disposed to go over into the critical ranks. Dillmann and Gunkel have adopted the newer views. The indispensable commentary in the New Testament field has been that of H. A. W. Meyer. Characterized by grammatical rigor and literary freedom, and brought up to date by frequent revisions, it has maintained itself as a standard authority for two generations. The principal contributor to the later editions has been Bernard Weiss, the present prince of all laborers in the exegetical field. Having completed more than 50 years of University service he stands to-day without a peer in his record of worthy achievement as a textual critic and commentator. He is incomparable for minute and searching investigation, exactness and solidity of scholarship. His associates in the Meyer Commentary series have been Wendt, Heinrici, Sieffert, Schmidt, Düsterdieck, and Beyschlag. Lipsius, Weizsäcker, Schmiedel, and Holtzmann have represented the more advanced school of commentators. Bleek did most admirable work in the earlier part of the century; and Luthardt and Hofmann have been conservative leaders in the later days.

Among the Dutch theologians the dominant tendency in the last century has been toward extreme radicalism. Scholten and Kuenen have represented advanced thought in the Old Testament field, while Loman, Pierson, Naber, Völter, and Van Manen have been generally considered hypercritical in the discussion of New Testament questions. Steck has represented the latter school in Switzerland; while Godet has nobly upheld the traditions of orthodoxy in this land. Godet combines a French felicity of style with a German thoroughness of scholarship and adds to these a genuine spiritual fervor which makes his commentaries on Luke, John, and Romans veritable masterpieces of exegesis. It may well be doubted if the century has produced more luminous and interesting contributions to this field.

France has furnished the brilliant and versatile and radical Renan, and the more profound and philosophical De Pressense; and it is making its influence felt to-day through the writings of the new Symbolo-Fideistic school, Stapfer, Sabatier, and Ménégoz being the chief theological representatives. This school emphatically repudiates the infallibility of Pope or Church and just as emphatically renounces the infallibility of Scripture or the Christ recorded in Scripture. It believes that philosophy can never deduce any religious truth from its premises, and so repudiates rationalism as a foundation for faith. It believes in a Divine revelation through the immanent Spirit of God. It identifies prayer and religion. All expression of religious impression must be through images or symbols. "All religious formulas are symbolic formulas; and Dogmatic itself is a great system of symbols" (Ménégoz). The essence of the gospel is to be distinguished from what is merely contingent. Jesus is the perfect manifestation of God in man. Salvation is by faith and faith consists in repentance and heart-surrender to God. The advocates of this school confidently claim that the future belongs to them.

In Great Britain the century has furnished some masterly exegetical work. Cambridge University has easily taken the honors in this field. Dean Alford in his 'Commentary on the Greek Testament' introduced the best results of German exegesis to English readers. Bishop Ellicott gave splendid examples of painstaking investigation of the Scriptural text. The great trio of later Cambridge scholars, Lightfoot, Westcott, and Hort have reached the highwater mark of English scholarship in their field. Bishop Lightfoot's commentaries upon the Pauline Epistles have been standard authorities ever since their publication. Westcott did equally fine work upon the writings of John and the Epistle to the Hebrews. Hort was generally reputed to be the greatest scholar of the three, but his extreme modesty and his realizing sense of the yet unattained perfection possible in his work kept him from the publication of any but fragmentary treatises. His influence lives among his students and associates. Mayor on James and Swete on Mark are worthy companions of the other Cambridge University commentaries. Prof. Davidson of Edinburgh was the leading Hebrew scholar of Great Britain in the century, and his pupils, W. Robertson Smith and George Adam Smith and others, have done yeoman service in revolutionizing and revitalizing the exegesis of the Old Testament. Sanday, Driver, Plummer, Beet, Findlay, Bruce, and Dods have done excellent interpretative work. The 'International Critical Commentary' and the 'Expositor's Greek Testament,' now in process of publication, bid fair to continue the best traditions in English exegesis.

America has had a share in the exegetical labor of the century. Moses Stuart, J. A. Alexander, Hackett, Hodge, Shedd, Harper, Mitchell, Moore, Toy, Vincent, and others have produced exegetical studies of acknowledged merit. Albert Barnes, Henry Cowles, J. A. Broadus, and D. D. Whedon have published series of helpful and devotional commentaries. Ezra Abbot, Edward Robinson, McGiffert, Mathews, Burton, Briggs, Bacon, Gilbert, Stevens, Allen, and Smyth have done first-class service in special fields.

The Roman Catholic Church began the century with two most worthy representatives of Biblical learning. Hug ably combated the rationalistic tendencies of his day and defended the traditional views of the origin of the New Testament writings. Herbst performed the same service for the Old Testament. During the greater part of the century, however, free inquiry has been more or less stifled by the authority of "the usual exegesis of Scripture." Scientific research has been systematically discouraged and any tendency toward a new or modified interpretation of the Scriptural text and any originality of conclusions, such as may not be guaranteed by the authority of the Fathers and the Councils of the Church, have been frowned upon by those in the places of power. A better condition of affairs seems to be on the point of realization now. A growing body of students within the pale of the Church have felt the influence of the great onward movements in the Protestant world and are beginning to demand the privilege of free inquiry and the use of modern methods in exegesis. They point to the critical work in the writings of Origen and Jerome and Eusebius and other Christian scholars and saints as proof that scientific research is no novelty in the Catholic Church, and they claim the right to follow in the footsteps of these illustrious critics of antiquity. A measure of freedom would seem to be already granted them since Pope Pius X. has written to Bishop Le Camus, "We should not approve the attitude of those who in no way dare to depart from the usual exegesis of Scripture, even when, faith not being at stake, the real advancement of learning requires such departure. You follow a wise middle course, and by your example show that there is nothing to be feared for the sacred books from the true progress of the art of criticism, nay that a beneficial light may be derived from it, provided its use be coupled with a wise and prudent discernment" (Dated Jan. 11, 1906). What this "wise and prudent discernment" may be is probably best illustrated in the decisions of the Biblical Commission appointed by Leo XIII., in its report upon the Pentateuch, published in the *Revue Biblique* and dated June 27, 1906. The report is presented in the form of questions and answers in catechism style. They may be summarized as follows: May one assert that Moses was not the author of the Pentateuch, but that it was made up largely of later elements? No. Must Moses then have written the whole of the Pentateuch with his own hand, or dictated it to secretaries? No. May Moses have committed the editing of it in whole or in part to secretaries and have permitted the publication of it under his name? Yes. May he have used sources, documents or oral traditions, borrowing sometimes the words, sometimes the sense? Yes. May the Pentateuch have undergone modifications, "additions made after Moses' death by an inspired author, glosses and parenthetical explanations, ancient words and phrases turned into more modern language, false readings to be attributed to errors of copyists, which criticism may examine and weigh according to its principles? Yes, the Church reserving judgment." The rights of the newer criticism to a hearing and standing in the Church are clearly allowed in this report, while the Church reserves the right to judge to what extent the findings of the critics may be compatible with its authority and peace.

Historical criticism has now come to the fore. The allegorical interpretation is discredited, it is to be hoped, finally and permanently. A vaster knowledge is at the service of the exegete than has been possible in any preceding age. The battles of the giants would seem to have ended for the time at least, and much of the smoke of conflict has cleared away. What ought the twentieth century exegesis to be? It ought to be capable of the production of both popular and critical work. It ought to meet the demand for edification on the part of the most humble and unlearned; and at the same time it ought to be proficient in the most exhaustive scholarship. It has at its disposal the accumulated wealth of material collected in the preceding centuries; and it may profit by the defects as well as the excellences of the masters who have gone before. Biblical knowledge was never more profound or more prevalent than now. The original text has been determined within approximate accuracy. The Bible has been freed from multiplied errors of manuscript transcription and restored to something like its original form and revelation. The original languages are better understood. The study of ancient inscriptions and fragments of newly discovered papyri have thrown a flood of light upon many new points. Modern travel and exploration and excavation in the Orient have taught us many things concerning the manners and customs of the ancient times. The marvellous advance made in the last century along the lines of scientific investigation and metaphysical research and literary criticism has had its beneficial influence upon the interpretation of the Bible. The exegete of to-day has an unprecedented equipment, and his task is comparatively clear. To-day, "the great body of evangelical expositors are united on the fundamental principles of interpretation. They agree that a proper commentary on the Bible or on any part of it, should clearly set forth the true meaning of the words and the train of thought intended by the sacred writer; and it should point out the grammatico-historical sense of every passage, giving careful attention to the context, scope, and plan" (Terry, 'Biblical Hermeneutics,' p. 738). The great exegetical works of the present are characterized by directness, accuracy, learning, independence of research, a careful consideration of the context and all the light that historical and literary criticism can throw upon the theme. There is a better conception of the nature of inspiration and more freedom in the exercise of the critical faculties of the commentator. Rationalism has come to its rights, together with a recognition of the due restraint laid upon the student of a divine revelation. Having escaped from the tradition of an absolutely inerrant text and a form of revelation infallibly fixed for all time, the exegete of to-day is freer to turn from the letter that killeth to the spirit that maketh alive. The tendency of the times seems to be away from the dominance of the Latin and the Reformation theology to the purer exegesis of the primitive faith. With the broader spirit of the Greek fathers and the better critical apparatus of the present day the promise of work in this field was never brighter than now.

Meyer, 'Geschichte der Schrifterklärung' (5 vols. 1802-8); Ernesti, 'Institutio Interpretis Novi Testamenti' (5th ed. 1809); Marsh, 'Lectures on the Criticism and Interpretation of the Bible' (1842); Lücke, 'Grundriss der neutestamentlichen Hermeneutik' (1817); Schleiermacher, 'Hermeneutik und Kritik' (1838); Klausen, 'Hermeneutik. German translation from Danish' (1841); Immer, 'Hermeneutik des neuen Testaments' (1873); English translation (3d ed. 1890); Doedes, 'Manual of Hermeneutics' (translated from the Dutch, 1867); Samuel Davidson, 'Sacred Hermeneutics' (1843); Fairbairn, 'Hermeneutical Manual' (1858); Cellérier, 'Manuel D'Herméneutique Biblique' (1852); Elliott and Harsha, 'Biblical Hermeneutics' (chiefly a translation of the foregoing, 1881); Lange, 'Grundriss der Biblischen Hermeneutik' (1878); Hofmann, 'Biblische Hermeneutik' (1880); Farrar, 'History of Interpretation' (1886); Terry, 'Biblical Hermeneutics' (3d ed. 1890). This is probably the best book on the subject in English.

D. A. Hayes,
Professor of New Testament Exegesis, Garrett Biblical Institute, Evanston, Ill.

Exelmans, ĕks-ĕl-mŏng, **Remy Joseph Isidore,** Comte: French soldier, Marshal of France: b. Bar-le-duc, 13 Nov. 1775; d. 22 July 1852. He entered the army in 1791, when only 16 years of age, and by 1799 had reached the rank of captain. He subsequently served with great distinction under Macdonald and Championnet in the campaign of Naples, and in 1801 was appointed to the staff of Murat as aide-de-camp. He was arrested in 1808 while serving with Murat in Spain, and sent to England, but after three years of confinement there effected his escape and in 1812 joined Napoleon in his Russian campaign. For brilliant conduct during this campaign he was appointed general of division by Napoleon but upon the Emperor's fall was banished from France owing to his Napoleonic inclinations. He was, however, permitted to return in 1819 and seems to have been highly esteemed under every successive government. He was restored to the Chamber of Peers in 1831 by Louis Philippe and Louis Napoleon appointed him grand chancellor of the Legion of Honor, and on 11 March 1851 created him Maréchal de France. He was subsequently thrown from his horse which resulted in his death.

Exercise, Physical. The upbuilding of the muscular system of the body is of prime importance in preserving the health or the curing of disease, and whether by passive motion or volitional activity is now recognized as necessary to keep the various functions of the body in normal condition. Artificially devised methods have been brought into use but regular daily out-of-doors exercise is preferable. Instruction in gymnastics is now given in many educational institutions and public schools, well-appointed gymnasiums being maintained for that purpose. In these gymnasiums outdoor sports are often practised, but the chief courses of exercise consist of a systematic use of dumb-bells, wands, Indian clubs, horizontal and parallel bars, chest-weights, swinging rings and other specialties. In many gymnasiums there are running tracks, baseball cages, swimming tanks, bowling alleys, etc. The chief outside sports are tennis, golfing, bicycling, baseball, football, rowing, walking, running, skating, swimming, and the various forms of track athletics. See GYMNASIUM, HISTORY OF; HYGIENE; PHYSICAL TRAINING; EDUCATIONAL ATHLETICS; etc.

Exercises, Spiritual. See SPIRITUAL EXERCISES.

Exeter, England, a city, seaport, and county, parliamentary and municipal borough, in the county of Devon, on the left bank of the Exe, 10 miles northwest from its outlet in the English Channel, on the Great Western and London and Southwestern railways. Though still presenting many indications of antiquity, the city can now boast of as handsome squares, terraces, streets, and houses, all of modern erection, as any other in the kingdom. The principal object of interest is the cathedral, a noble edifice of high antiquity. It is cruciform, 408 feet in length, and consists of a nave, with two side aisles; two short transepts formed out of two heavy Norman towers, each 130 feet in height; a choir of the same width as the nave, and 128 feet in length; 10 chapels or oratories, and a chapter-house. The west front is richly decorated, presenting one of the most picturesque façades of any building in Europe. The interior, now restored by Sir G. Gilbert Scott, is magnificent. Other architectural antiquities are the remains of the castle of Rougemont, portions of the ancient city walls of Athelstan, Norman work in some of the churches, and the noble guild-hall, tastefully restored. Among several fine modern churches Saint Michael's may be mentioned. Among the numerous educational establishments is the Exeter school, founded by the citizens in the time of Charles I., to which there are a number of free scholarships. It has 16 exhibitions to either of the Universities of Oxford or Cambridge. The Exeter Diocesan Training College is also situated in the city. The charitable institutions of various kinds are numerous. They comprise the Devon and Exeter Hospital, many almshouses, a dispensary, a lunatic asylum, a deaf and dumb institution, a penitentiary, an eye infirmary, a lying-in charity, a humane society, a stranger's friend society, etc. The principal scientific and literary institutions are the Devon and Exeter Institution for the Promotion of Science, Literature, and Arts, established in 1817, and possessing a valuable library; the Exeter Literary Society, established in 1835; and the Royal Albert Memorial College, Museum, and Free Library, whose enlarged buildings were opened in 1899. The college has over 1,000 students. Exeter is not an industrial town, its woolen manufacture, once one of the largest in England, being extinct; but it has iron-foundries, manufactories of agricultural implements, paper-mills, corn-mills, tanneries, etc. Glove-making and lace-making are also carried on. By means of a canal, 5 miles in length and 15 feet in depth, vessels of 400 tons can reach the city, and there is a large floating basin. The Exe itself is not navigable to the city. Exeter is a place of remote antiquity, having been a British settlement long prior to the invasion of the Romans, by whom it was called *Isca Damnoniorum.* Pop. (1901) 46,940.

Exeter, N. H., town, one of the county-seats of Rockingham County; on the Squamscott River, the Boston & M. R.R.; 26 miles east of Manchester, and about 13 miles southwest of Portsmouth. Exeter was founded in 1638 by John Wheelwright, a Congregationalist clergyman, who was banished from Massachusetts. Massachusetts claimed control over the place until 1680. It was the capital of New Hampshire, and the centre of military movements of the colony during the Revolution. The town is well known as the seat of the Phillips Exeter Academy (q.v.), established in 1781. The Robinson Female Academy is located in Exeter. The town contains a large public library and a number of manufacturing establishments: a large shoe factory, cotton-mills, iron, brass, and machinery manufactories. Pop. 5,010. Consult: Fassett, 'Colonial Life in New Hampshire'; Bell, 'History of the Town of Exeter.'

Exeter Book, or **Codex Exoniensis,** a unique manuscript of Anglo-Saxon poetry in the library of Exeter cathedral. It was presented to the chapter by Leofric, first bishop of Exeter (1050–72), contains 246 pages of vellum, and is the extant original copy of some valuable remains of Anglo-Saxon literature. The text with a translation is to be found in Gollancz, 'The Exeter Book' (1895).

Exeter College, Oxford. This college, originally called Stapledon Hall, was founded by Walter de Stapledon, bishop of Exeter, sometime lord high treasurer of England, who removed to this place his scholars from Hart Hall, and made a foundation for a rector and 12 fellows. In 1404 Edmund Stafford, bishop of Exeter, added two fellowships and obtained leave to give the college its present name. In 1565 Sir William Petre, secretary of state, added eight; in 1636 Charles I. annexed one for the Channel Islands, and lastly, Mrs. Shiers left certain rents in 1770, out of which two fellowships were founded. Under the authority of 17 and 18 Vict., cap. lxxxi., the fellowships (a number of which were appropriated to various archdeaconries or counties) were reduced from 25 to 15, and were thrown open; they are now 12 in number. From the revenues of suppressed fellowships over 20 scholarships were founded, eight of which (called Stapledon scholarships) are limited to persons born or educated in the diocese of Exeter, and one or more to persons born in any of the Channel Islands, or educated at Victoria College, Jersey, or Elizabeth College, Guernsey.

Exeter Hall, a large building on the north side of the Strand, London, opened in 1831. It is capable of containing over 3,000 persons. In it the "May Meetings" of the several religious societies are held. It is now the property of the Young Men's Christian Association.

Exhaus'tions, Method of. The ancient geometricians employed the method of exhaustion for determining the areas of curves, and for the solution of similar problems. The method consists in comparing the magnitude to be determined with rectilinear magnitudes; thus, the area of a curve with the area of a polygon constructed so as to be comparable with the curve in question. The use of the method is exemplified in the second proposition of 'Euclid's Twelfth Book.' The method was applied with all the rigorous logical exactness for which the Greek geometricians are so famous. See GEOMETRY; MATHEMATICS.

Exhibi'tion, an endowment or benefaction. See ENDOWMENT.

Exhibition, Industrial. The promotion of trade and manufactures by means of collections of works of industry and art has no claim to the merit of novelty. In modern times, however, the idea has been more systematically carried out, and was probably suggested by the good effects produced by two institutions of a like nature — the galleries of rare productions of art or nature collected by the wealthy and educated, and the exposure for sale of ornamental and useful articles in the stores of individuals, and more particularly on a large scale at the great fairs which in former times were more important features of commercial enterprise than they now are. The beneficial effect thus derived from the exhibition and comparison of the manufactured products of different localities could not long escape notice. In England this knowledge was brought to practical purposes in the 18th century, when the Society of Arts in 1756–7 not only offered prizes for specimens of manufactures, but exhibited the works of the competitors. In France an exhibition embracing all kinds of manufactures was held in the year 1798, and another under the consulate of Bonaparte in 1802, and the gratifying results attained led to the idea of holding them every three years, which was carried out as far as the political troubles of the country would allow. Many exhibitions were subsequently held at different cities on the continent of Europe, and in the British Islands exhibitions of a more or less local nature were held in Dublin, Manchester, Liverpool, and Birmingham, as well as in London in the premises of the Society of Arts. All these had been generally successful, but the necessity of having an exhibition on an international scale had become with some a fixed idea. This was first brought fairly before the British public in 1848 by Prince Albert, then president of the Society of Arts. In 1849 the project for an exhibition in which all nations might join began to take a tangible shape; and it was at last determined by government to issue a royal commission to deal with the matter, which was gazetted 3 Jan. 1850. The better to enable the commissioners to enter into contracts and otherwise incur obligations, subscriptions were procured to a guarantee fund, the queen leading the list with $5,000. A vast structure of iron and glass, generally designated the Crystal Palace, built from the design of Joseph Paxton, was erected in an incredibly short space of time in Hyde Park, London, and was opened by Her Majesty on 1 May 1851. The extreme length of the building was 1,851 feet, the width 408, and the height about 64 feet. The entire area was about 19 acres. In the ground floor and galleries there were about eight miles of tables set apart for the exhibitors. The articles sent for exhibition were divided into four great sections: Raw materials, machinery, manufactures, and fine arts. The number of exhibitors was about 15,000. The exhibition remained open until 11 October, and the number of visitors during the 144 days amounted to about 6,170,000. After all expenses were defrayed there was a balance of $700,000 left. The immense success of the undertaking encouraged the local and national exhibitions of Dublin and New York in 1853 and of Munich in 1854; and the French nation in 1855 opened its first Exposition Universelle. The main building was an imposing structure of white stone and of classic architecture. The buildings were erected in the Champs Elysées, and covered about 24 acres. There were in all about 24,000 exhibitors, and the contents were pronounced greatly in advance of those exhibited in London in 1851. It was said that continental manufacturers had taken lessons from the British exhibition which the British had failed in fully profiting by, and so exhibited a vast improvement in works in which the latter considered themselves unrivaled. This was followed by the national exhibitions of the Dutch at Haarlem and the Belgians at Brussels, both in 1861, and the following year by the second great international exhibition held in London. It occupied a vast brick building, lighted by a roof and two immense cupolas of glass, and erected in the garden of the Horticultural Society at South Kensington. The space covered was about 17 acres. There were 26,348 exhibitors in the industrial division, of whom 8,487 were British, and in the fine art division 2,305, of whom 990 were British. The aggregate number of visitors from 1 May to 31 October was 6,211,103, giving an average of 36,328 per day. The productions, which came from almost all parts of the globe, were divided into 40 classes, and included manufactures of all kinds — machinery, chemical products, railway plant, and ordinary vehicles, animal and vegetable products used in food or manufacture, architecture, painting, sculpture, engraving, etc. This exhibition was also eminently successful, and enabled the public to judge of the progress or shortcomings of British home manufactures and art as compared with others. In 1865 a rather important exhibition was held in Dublin which was a pecuniary failure. The second French International Exhibition was opened on 1 April 1867, and closed on 3 November. On 1 May 1871 the first of the British annual international exhibitions of fine arts and industry was opened by the Prince of Wales. On 1 May 1873 the first Austrian international exhibition was opened by the Emperor Franz Josef with great pomp and ceremony. The building was situated in the Prater, or, as it may be called, the park of Vienna, and was 2,940 feet in length, with an average breadth of 570 feet. A great exhibition was opened by President Grant at Fairmount Park, Philadelphia, upon the occasion of the centennial festival of the American declaration of independence. It occupied 60 acres, and had nearly 10,000,000 visitors. A third French International Exhibition was held at Paris in 1878; area occupied 140 acres; visitors 17,000,000. A fourth French International Exhibition was opened by President Carnot in 1889 to commemorate the centenary of the Revolution, the visitors to which numbered over 25,000,000. One of its chief features was the Eiffel tower, of iron, 984 feet high. The series of exhibitions which were held at South Kensington, London, included The Fisheries (1883), The Health (1884), The Inventions (1885), and the Exhibition of Colonial and Indian products (1886); the latter of which was visited by 5,550,749 visitors. Besides these, exhibitions have been held in Edinburgh (1886), at which there were 2,769,632 visitors; Manchester (1887) at which there were 4,765,000 visitors; and Glasgow (1888), with 5,748,379 visitors. In 1899–1900 a huge International Exhibition was held at Paris, but, though visited by about 47,000,000 persons, was not a financial success. It occupied the Champ de Mars and extensive areas on both sides of the Seine.

In 1893 the fourth centenary of the discovery of America by Columbus was celebrated by the World's Columbian Exposition, at Chicago. It excelled all predecessors in conception, scope, and grandeur. Every nationality contributed to the exhibits, and many countries possessed their own buildings. The "White City," as it was called, was opened by President Cleveland, 1 May and closed 30 October. It occupied about 600 acres, at Jackson Park, on the shore of Lake Michigan, including the "Midway Plaisance." Nearly every State in the Union was represented by its own edifice. The principal buildings were Machinery Hall, the Art Palace, and those devoted to transportation, mining, electricity, agriculture, manufacture and liberal arts (covering 44 acres), government, administration, fisheries, horticulture, and anthropology. The total admissions for the period named were 27,539,521, and the receipts from this source $10,317,814. The largest attendance on any one day — Chicago day, 9 October — was 716,881. Other notable exhibitions in the United States were the California Mid-Winter Exhibition, held in San Francisco in 1894; the Cotton States and Industrial Exposition held in Atlanta, Ga., September to December, 1895; the Tennessee Centennial Exposition, held in Nashville, Tenn., 1 May to 31 Oct. 1897; the Trans-Mississippi Exposition in Omaha, Neb., 1 June to 1 Nov. 1898; the Pan-American Exposition, in Buffalo, N. Y., from 1 May to 2 Nov. 1901; the South Carolina Inter-State and West Indian Exposition, held in Charleston, from 1 Dec. 1901 to 1 June 1902, and the World's Fair at St. Louis, Mo., in 1904, in celebration of the Louisiana Purchase, its projectors claiming for it "the greatest exposition in all history. The buildings in Forest Park to the number of 15 great structures stand in a tract of 1,180 acres, and the total amount of money expended exceeds $15,000,000. A feature of the exhibition was 250 original groups of sculpture containing 1,650 figures. The exhibition included an air-ship contest, a fashionable horse show, a live stock show covering 40 acres, and a Philippine exhibit covering 50 acres. See FAIRS.

Ex'moor, a wild and hilly district in the extreme southwest of Somersetshire, extending also into Devonshire, England. It was formerly a forest, but, with exception of a considerable portion lately cultivated, it is now mostly heath and marsh. It embraces ranges of hills of considerable elevation (the loftiest being Dunkerry Beacon, 1707 feet), and in the time of the Druids was a favorite spot for the celebration of their religious rites. Red deer still exist here in a wild state. Good descriptions of Exmoor may be found in Blackmore's 'Lorna Doone,' and Sir Conan Doyle's 'Micah Clark.'

Exmouth, ěks'mŭth, **Edward Pellew,** VISCOUNT, English naval officer: b. Dover, England, 19 April 1757; d. 23 Jan. 1833. He served as midshipman in the Blonde frigate during the American Revolution, and greatly distinguished himself at Lake Champlain. In 1809 he had attained the rank of vice-admiral, and in 1814 he was made Baron Exmouth. In 1816 he proceeded to Algiers in command of a combined fleet of English and Dutch ships to enforce the terms of a treaty which the dey had violated. He bombarded the city for seven hours, and inflicted such immense damage that the dey consented to every demand. Twelve hundred Christian slaves were by this exploit restored to liberty. Lord Exmouth was raised to the dignity of a viscount for this service.

Exmouth, England, seaport, market town in the county of Devon; on the English Channel at the entrance to the estuary of Exe. It is one of the favorite resorts, on the coast of Devon, for sea-bathing. The chief industry is fishing, and the shipping trade is considerable; the new docks are commodious. Exmouth was one of the principal ports of the country in the reign of Edward III.; but subsequently it became a mere fishing hamlet. Late years it has increased steadily in population and trade. Pop. (1901) 10,500.

Exodus (Gr. "departure"), the name given in the Septuagint version to the second book of the Pentateuch, because it describes the departure of the Israelites from Egypt. The contents of the book, though not embracing such a variety of incidents as Genesis, are of a more diversified character, being not only historical, but also, and in a greater part, legislative. The subject-matter, arranged according to historical order, forms three divisions. (1) The condition of Israel in Egypt, and the preparations for their departure (ch. i.-xii. 36). (2) The march from Rameses to Mount Sinai (ch. xii. 37-xix. 2. (3) The abode in the desert and the promulgation of the Sinaitic Law (ch. xix. 3-xl).

Exog'amy, the usage by which in many primitive races a man is forbidden to marry a woman of his own stock or tribe. See MARRIAGE; TRIBE.

Exogenous (ĕks-ŏj'ĕ-nŭs) **Plants,** an old and now disused name for dicotyledons. Monocotyledons were similarly known as endogenous plants, or endogens. See BOTANY.

Exophthal'mic Goitre, enlargement with turgescence of the thyroid gland, accompanied by protrusion of the eyeballs, breathlessness, palpitation, and anæmia. Also called Basedow's or Graves' disease (q.v.).

Ex'orcism, the act of expelling evil spirits by adjuration. The word is of Greek origin, *exorkismos,* from the verb *exorkizo,* which in classic Greek means to put one on oath, but in the New Testament to drive out by adjuration. Demonic possession was a notion generally entertained by the Jews in the time of Christ; and that it was entertained by Jesus Christ and his apostles is as certain as any fact recorded in the Scripture. Hence, till modern times it was believed by all Christians, though now it is repudiated expressly or tacitly, or is explained in a naturalistic sense, or at least ignored by very many who profess belief in the gospels as a divine revelation and the very word of God. The Catholic Church, while it does not stand committed to the popular beliefs of the faithful upon this matter, nor to the views even of her most eminent doctors, except so far as she may have formally adopted them in her authoritative symbols, claims to possess and to exercise in these days no less than in apostolic times the power to expel evil spirits from the obsessed or possessed. One of the minor orders of clergy in the Catholic Church is that of the "exorcist," and the ritual of the Church to this day has an official formula of prayers and adjuration for driving out demons. Pope Innocent I. (d. 417) forbade exorcists to exercise their ministry save with the express permission of the bishop, and that rule is still in force.

Ex'orcist, the name of one of the minor orders of the clergy in the Roman Catholic Church. See ORDERS, HOLY; EXORCISM.

Exosmo'sis. See OSMOSIS.

Exostem'ma, a genus of American shrubs and trees of the natural order *Rubiaceæ,* several species of which yield barks sometimes used in medicine. Though closely related to the genus *Cinchona* (q.v.) which yields quinine, the species of this genus are lacking in similar alkaloids. St. Lucia bark and Caribbee bark, obtained from West Indian species, are probably the best-known.

Exoter'ic. See ESOTERIC.

Exot'ic, an appellation for the produce of foreign countries. Exotic plants are such as belong to a soil and climate different from that to which they have been transplanted. It is implied that the exotic is more or less of a rare or tropical character and can be preserved only in greenhouses.

Expan'sion. See TERRITORIAL EXPANSION.

Expansion, in physics, is the increase in the bulk of bodies, in consequence of a change in their temperature. This is one of the most general effects of heat, being common to all bodies whatever, whether solid or fluid. The expansion of solid bodies is determined by the pyrometer, and that of fluids by the thermometer. The expansion of fluids varies considerably, but, in general, the denser the fluid, the less the expansion; thus water expands more than mercury, and spirits of wine more than water; and, commonly, the greater the heat, the greater the expansion; but this is not universal, for there are cases in which expansion is produced, not by an increase, but by a diminution of temperature. Water furnishes us with the most remarkable instance of this kind. Its maximum of density corresponds with 39.2° F. This fact is of the utmost importance in the economy of nature. When the surface of rivers and lakes is cooled, the superior layer of water sinks, and warmer water from below takes its place till the whole mass is cooled to 40°. After this the circulation ceases, and ice is formed. The maximum density point of sea water is considerably lower than that of fresh water, and varies with the quantities of the salts contained in it. The expansion of water is about the same for any number of degrees above or below the maximum density point. Thus, if we heat water 5° above 39.2°, it occupies the same bulk as it does when cooled down to 5° below 39.2°: and the density of water at 32° and at 53° is very nearly the same. The force with which water expands in the act of freezing is shown when glass bottles are filled with water and sealed; the glass is broken in pieces when the water freezes. A brass globe, whose cavity is an inch in diameter, may be burst by filling it with water and freezing it; and the force necessary for this effect is 27,720 pounds weight. The expansive force of freezing water may be explained by supposing it the consequence of a tendency which water in consolidating is observed to have to arrange its particles in one determinate manner, so as to form prismatic crystals, crossing each other at angles of 60° and 120°. The force with which they arrange themselves in this manner must be enormous, since it enables small quantities of water to overcome so great mechanical pressures. This observation is conspicuously illustrated by observing the crystals of ice on a piece of water exposed to the action of the air in frosty weather; or upon a pane of glass in a window of a room without a fire at the same season. Various methods have been tried to ascertain the specific gravity of ice at 32°; that which succeeded best was to dilute spirits of wine with water till a mass of solid ice put into it remained in any part of the liquid without either sinking or rising. The specific gravity of such a liquid is 0.92, which, of course, is the specific gravity of ice, supposing the specific gravity of water at 60° to be 1. This is an expansion much greater than water experiences even when heated to 212°, its boiling-point. We see from this that water at the instant of solidification receives a sudden and considerable augmentation of bulk. See HEAT.

Expatria'tion, the voluntary renunciation of the rights and liabilities of citizenship in one country, in order to become the citizen or subject of another. The right of a citizen of one country to renounce his allegiance in order to adopt another country as his own, has and is still much disputed. It seems most reasonable that the mother country and not the individual should decide the question. In the early part of the 19th century the United States was almost the only nation that claimed for individuals the right of expatriation without the consent of the government of which they were citizens or subjects. The European nations, as a rule, maintained that the permission of the sovereign was necessary; and the enforcement by England of this claim was one of the causes of the War of 1812. The right of voluntary renunciation of allegiance to the United States by one of our citizens was unsettled, so far as legislation was concerned, till the Act of Congress of 27 July 1868, asserted that expatriation "is a natural and inherent right of all people," but the action of the department of State had previously seemed practically to admit the right. The first formal recognition of this principle was secured in an expatriation treaty with the North German Confederation, signed 22 Feb. 1868. England first recognized the right of voluntary expatriation by act of Parliament in 1870, and immediately concluded an expatriation treaty with the United States. All the leading nations of Europe now recognize the right, including besides those just mentioned, France, Austria, Russia, Italy, and Spain. The laws of the various nations upon this subject have been published by the United States government, under the title 'Opinions of the Principal Officers of the Executive Department and other Papers, Relating to Expatriation, Naturalization and Change of Allegiance' (Washington 1873). See also CITIZEN.

Expecta'tion. See PSYCHOLOGY.

Expectation Sunday, the Sunday before Whitsunday. Acts i. 4, Christ commanded the disciples "that they should not depart from Jerusalem, but wait for the promise of the Father." They waited till the day of Pentecost and the promise was fulfilled.

Expectation Week, the week, or rather the nine days, which elapsed between the ascension of Jesus and the Pentecostal effusion of the Spirit, because during that interval the apostles and early Church waited in expectation that the promised Comforter would come.

Expectorant, a remedy used to increase the amount of secretion of the lower respiratory tract — the trachea and bronchi. Such remedies act: (1) Through nervous influences, like those of ipecac, antimony, senega; or (2) they increase the amount of blood flowing around the bronchi; or else (3) they stimulate the mucous membranes of the bronchi as they are excreted. To this latter class potassium iodide, chloride of ammonium, the aromatic balsams, and squills belong. They are useful in chronic stages of catarrhal bronchitis. See BRONCHITIS.

Expectoration, technically termed sputum, is a physiological secretion, but when there is an excess of secretion of mucus in the bronchi and trachea, which is expelled by hawking or coughing, it becomes a diseased condition. Excessive expectoration is found in bronchitis, in pneumonia, in tuberculosis, in gangrene of the lung, and in influenza. In all of these conditions the sputum carries the germ of the disease and should be disinfected. Miscellaneous expectoration in the street and public places should be prohibited by law. To properly disinfect the sputum, it should be received in a paper spitcup or appropriate pocket-flask, and later destroyed. A mixture of carbolic acid, 1 to 25 of water, or of chlorinated lime, a teaspoonful to a pint of water, should be used in spittoons if these are essential. In cases of tuberculosis and influenza particularly, great care should be taken of the sputum and of all handkerchiefs, towels, napkins, and other linen that come in contact with the patient. See DISINFECTION; INFLUENZA; TUBERCULOSIS.

Expeditions to Latin America. See DISCOVERIES OF AMERICA.

Experiment, an operation designed to discover some truth, principle, or effect, or to establish or illustrate it when discovered. It differs from observation in the fact that the phenomena observed are, to a greater or less extent, controlled by human agency. Experiment distinguishes the modern method of investigating nature, and we owe to it the rapid strides made in chemistry, physics, and other sciences.

Experiment Stations, Work of. The agricultural experiment stations of the United States government now form the most complete system of agricultural research in the world. Over 1,000 trained and practical men are now employed in the 60 stations, which are now in operation in every State and Territory, including Alaska, Hawaii, Porto Rico and the Philippines. The annual income of these stations in 1902 was $1,328,847, of which sum $720,000 came from the Federal government, and $608,847 from State appropriations and other sources. The stations have existed as a national enterprise for 14 years, and the outlay for agricultural investigation in that time has been at the rate of $1 for nearly $3,000 worth of farm products, which cannot be considered an extravagant outlay.

Our farmers spend over $50,000,000 a year for fertilizers, and the stations have given particular attention to this subject. Fraud and extravagant assertions about fertilizers have been largely eliminated from the business and thousands of farmers are buying fertilizers more intelligently and economically. The annual loss to farmers from waste of barnyard manure is estimated at $7,000,000. Many of the stations have given special attention to the economic use of manure on the farm, with the result that better methods for its care and use are being employed. The successful introduction of Mansury barley, for which the Wisconsin station is mainly responsible, has increased the yield of barley over a wide region, with results worth millions of dollars. Kaffir corn was introduced about 15 years ago by the stations in California, Kansas and Oklahoma. It has been found specially suited to regions of scanty rainfall. The crop in Kansas alone in 1899 was valued at over $6,000,000.

The various macaroni wheats which have been tested under varying conditions by a number of the stations, have proved so successful that the United States will probably produce all the macaroni it consumes in the course of a few years. The investigations of the experiment stations in the southern States have convinced farmers that many varieties of forage plants may be more successfully grown in the South than was supposed and have laid the foundation for a wide development of the live stock and dairy industries of that region. The department of agriculture and the Connecticut State station, co-operating with local tobacco growers, have within the last three years demonstrated that a fine grade of Sumatra wrapper tobacco may be grown under shade in the Connecticut valley. Prof. Whitney says that this discovery will increase the value of the light lands of the Connecticut valley over 200 per cent. The stations of the northwestern States have extended the limits of corn culture by proving, by careful selections of varieties and modified methods of culture, that this crop may be grown in regions heretofore believed to be unsuited to corn culture. The stations have been prominent in the investigations which have led to the new system of forcing vegetables in the field and under glass for supplying the markets with fresh vegetables at all seasons of the year. For example, the winter culture of lettuce in eastern North Carolina is now yielding over $100,000 a year. The Ohio station discovered that onions started in the greenhouse or under frames from seed and then transplanted to the open field produce larger onions and earlier and heavier crops than by the usual methods of tillage and seeding. This discovery is changing the methods of onion culture.

These are only a few of the many ways in which the experiment stations are helping agriculture. Their investigations relating to protective measures against plant diseases and injurious insects, the storage and utilization of fodder crops, breeding and dairying, the protection of farmers against fraud, and many other topics have been of the utmost value. See AGRICULTURE; AGRICULTURAL EXPERIMENT STATION.

Expert. See EVIDENCE.

Expert Testimony. A branch of the law of legal evidence which may be defined as testimony in the form of an opinion, based upon facts proved in an action by other witnesses, or upon facts assumed to have been proved, concerning matters involving scientific or technical knowledge.

The value of expert testimony was recognized in the Roman law and was incorporated in that system of jurisprudence. In the law of some continental countries the system has always been firmly established. Indeed, in those countries, all forms of opinion evidence was and still is freely accepted: the courts giving it such weight as it seems entitled.

In the very earliest period of the English law, however, expert testimony was unknown. At that time a jury was selected from among persons already possessing knowledge of the facts of the case to be tried. In other words, during the early development of English law, the witnesses composed the jury and their verdict was based upon the facts within their own knowledge, and no effort was made to assist them. Gradually, however, the practice of taking testimony in open court came into vogue, and it was later seen, in order that an impartial verdict might be rendered, that the jury should be composed of unbiased persons, whose minds were not hampered by conclusions theretofore formed.

As a general rule in the English common law, which is, with slight modifications, the law of the United States, testimony of opinions has never been admitted as evidence. Our courts require and allow testimony as to facts only, and consider it the province of the court and jury to draw conclusions and form opinions from the facts proved. An exception to this rule is found in expert testimony. Since a jury represents only the average intelligence of the community, cases were early encountered where it was difficult or impossible for the jury to reach a reasonable conclusion from the facts proved before them, and to obviate the defect in the trial system, the courts gradually brought to its assistance expert witnesses, to aid in correctly determining questions presented. At that stage expert testimony was confined almost entirely to that of physicians. Causes of death or effects of physical injuries were then and still are the most common questions with which juries must deal, and the determination of such issues is dependent largely upon the opinions of skilled physicians, familiar with the conditions, testifying as experts. In later years in England and in the United States, expert testimony has been availed of to assist juries in various other classes of cases. The theory of the courts in allowing such testimony is, that the jury, or where the action is tried without a jury, the trial judge, is not competent to draw its own conclusion from the facts proved, without the aid of such testimony. In that event witnesses possessing technical or peculiar knowledge upon the subject are allowed to give their opinions as evidence for the enlightenment of judge or jury.

Within the last few years, the practice of employing expert testimony has grown rapidly and has resulted in the creation of a class of witnesses who might be termed professional experts, and who command large fees for their services. This has conduced to a result which has brought about much criticism, adverse to the system, based largely upon the fact that the testimony of expert witnesses involving lengthy technical discussions is one if not the principal cause of the unreasonable length of modern trials; upon the further fact that the testimony of the modern expert, with its technicalities and extreme length, tends rather to obscure than to enlighten the minds of a jury; but principally upon the fact that such testimony has proved in a great many cases to be so partisan as to be wholly unreliable. This criticism is not unmerited.

The creation of the class of so-called professional experts whose services demand large compensation has resulted in a condition where opposite opinions may be obtained in any number. Some of the recent prominent murder trials have hence afforded an interesting spectacle of arrays of experts with conflicting opinions retained by the respective parties, at great expense, whose examination and cross-examination has consumed days and even weeks, exhausting the patience of the judge, consuming the time of the courts, perplexing instead of clearing the issues, and weakening the confidence of the public in its system of justice.

Before the testimony of an expert witness is admitted, he must be qualified as an expert; in other words it must be shown by his own testimony that he has a knowledge derived from experience or study not possessed by the ordinary person in regard to the particular subject to which he intends to testify. Whether or not the witness has proved himself an expert is determined by the trial judge in his discretion.

The method usually adopted to get the testimony of an expert witness before the jury, after his qualification, is through the form of a hypothetical question. A question is put to the witness by the counsel of the party calling him, the question containing in detail the facts which the counsel believes have been proved and the witness is asked his opinion upon the assumption that the facts assumed are true. Such hypothetical question is often of great length, containing, as it does, a statement of facts that may have required days to prove. After the question is answered by the expert, he is usually subjected to a long cross-examination by the opposing counsel to test his skill and knowledge and the correctness of his conclusion. That the ordinary jury places little weight upon the conclusions of an expert based upon the facts contained in a hypothetical question, may be inferred from the fact that the counsel putting the question may assume facts which have not been proved to the satisfaction of the jury. Again the question is often so long involved that its meaning is soon lost.

In other cases, however, where the witness has knowledge of the facts, the hypothetical question is not necessary. For instance, the opinion of an expert in handwriting may be given after his comparison of the disputed writing with an admitted sample of handwriting used as a standard of comparison; and the physician who has examined a physical injury, or the alienist who has examined a person claimed to be insane, may testify as to his opinion based upon the knowledge acquired by him through such examination without the medium of a hypothetical question.

The courts do not consider expert testimony of great importance, or in any sense binding on the jury. It is allowed solely for the purpose of assisting the jury, and the courts take occasion to instruct a jury to attach such weight to expert testimony as in their minds it seems entitled or to disregard it altogether if they deem fit so to do. Such an instruction will be upheld even if there is no conflict in the expert testimony introduced.

In spite of the just criticism to which the modern development of expert testimony has been subjected, the doctrine has its uses and is necessary to our system of jurisprudence.

Thus, such testimony is absolutely indispensable to prove the custom in a trade; to prove the tensile strength of materials; the probable cost of buildings or works; the chemical composition of materials; the presence of disease and the cause and effects of disease or physical injury, and the cause of death; the seaworthiness of vessels and other nautical matters; and to assist the jury in various other matters not within the knowledge of the average judge or juryman.

Various remedies through legislation have been suggested to remedy the abuses to which expert testimony has been subjected, such as limiting the number of such witnesses to be called upon a trial; limiting the length of the testimony, forbidding an expert witness receiving any compensation beyond the ordinary fees of witnesses and even to the extent of forbidding expert testimony in some classes of cases, the most recent suggestion in connection with criminai cases being the creation of a board of experts retained and compensated solely by the state whose services may be invoked by either the people or the accused.

It may be suggested that the evil will, in time, work its own remedy through the agency of the courts without the aid of legislation. The judge presiding at the trial of an action has a wide discretion in allowing or disallowing the testimony of experts, and it may be said that a too liberal policy of allowing expert testimony without limit is largely the cause of the abuse.

HENRY M. EARLE,
Attorney, New York City.

Exploration in America. As the routes followed by explorers of North America were determined by its physical contour, a brief geographical survey is necessary to understand the progress of its exploration. Thus considered, the continent divides itself into four geographic provinces: the Atlantic coast region, the eastern mountains, the central region, and the western mountains. The first embraces the coastal plain and Piedmont plateau lying east of the Appalachians; the second the Appalachian Mountains and their northern extension to the Gulf of St. Lawrence; the third the whole Mississippi Basin, the Great Lake region, and the Hudson Bay drainage. The last province is the great cordillera of western North America, which lies west of the Mississippi Basin and includes the Rocky Mountain system, Pacific Mountain system, and the Great Basin region lying in between.

The Atlantic seaboard, which was the scene of the earliest exploration and settlement, is separated from the central region by the Appalachian barrier. Hence the St. Lawrence, lying beyond the northern terminus of this barrier, is the only easterly flowing river which drains any part of the central province; and as in an unexplored wilderness watercourses naturally offer the easiest routes of travel, it was by its valley that explorers first penetrated the continent. A way through the barrier was found by following the Hudson and its westerly tributary, the Mohawk, which is connected with Lake Ontario by a lowland area.

The central province is covered by a network of waterways extending nearly two thirds of the distance across the continent, from the inland margin of the Appalachians on the east to the front of the Rocky Mountains on the west. It is separated by low divides into three distinct drainage systems: the rivers emptying into the Gulf of Mexico through the Mississippi; the waters which feed the St. Lawrence; and the rivers tributary to Hudson Bay.

The western mountain belt stretches northward from Mexico through the United States and Canada to the Arctic Ocean. Its southern section is interlaced by a series of rivers tributary in part to the Rio Grande, flowing into the Gulf of Mexico; and in part to the Colorado River, flowing into the Gulf of California.

The easiest route across the continent lay near the present northern boundary of the United States, where the head waters of the Missouri reach far into the western mountains, only 500 miles from the Pacific, and separated by but one divide from the Columbia River basin, which leads directly to the Pacific. Geographically, then, the explorations of our country fall into four groups: (1) those along the Atlantic seaboard, made by colonists of various nationalities; (2) those along the Mississippi, made by the

Spaniards from the south, the French from the north, and pioneers breaking through the passes of the Appalachians from the Atlantic seaboard; (3) those made by the Spaniards northward from the Mexican border; and (4) those of the western mountains, made by Americans and of comparatively recent date.

Though the Cabots discovered North America in 1497 and claimed it for England, it was Spain who first attempted its exploration. Ponce de Leon, who had sailed with Columbus on his second voyage and subsequently become governor of Porto Rico, set out in 1513 in search of the "Fountain of Youth." Sighting an unknown coast at latitude 30° 8', he named the land "Florida," and turning south explored both sides of the peninsula. When he attempted nine years later to plant a colony on these shores, he was driven off by Indians.

But Spanish interest was aroused. In 1519 Cortes achieved his infamous conquest of Mexico, and the fame of its wealth inspired others to seek the New World. Pánfilo de Narvaez obtained a grant to conquer and govern Florida, by which was meant all the rest of the continent, stretching indefinitely northward from the Gulf of Mexico. With 300 men he landed at Tampa Bay in 1528, and marched northward, suffering terrible hardships. Disappointed at not finding the gold they sought, they returned to the coast near Appalachee Bay and set out for Mexico in improvised boats, but were wrecked by the way. Of the whole party, Cabeza de Vaca and three others were the only survivors. For six years they wandered: up through Mississippi across the Mississippi River near Memphis, along the Arkansas and Red rivers to New Mexico and Chihuahua; at last reaching Sinaloa on the Gulf of California, where they were found by Spaniards and taken to Mexico (1536).

Cabeza's written account of their experiences, published after his return to Spain, falsely attributed great wealth to Florida. So when Hernando de Soto, fresh from the conquests in South America, which had given him riches and fame, obtained permission to conquer Florida, many flocked to join him. He sailed in nine ships with 620 men, maintaining great display. Landing at Tampa Bay in 1539, the procession wandered westward, ill-treating the natives, for three years in pursuit of gold through the wilderness of the present Georgia, Alabama, Tennessee, and Mississippi to the banks of the Mississippi River. They crossed above the Arkansas, penetrated westward until frightened back by the roving prairie tribes, and returned to the Mississippi, where De Soto died and was buried in its waters at the mouth of the Red River (1542). His followers under Moscoso built seven brigantines, descended to the Gulf, and reached the Spanish settlement on the River Panuco, 311 survivors all told. Thus it was De Soto who first attracted attention to the Mississippi. Alonso de Pineda had discovered its mouth in 1519, and named it "Espiritu Santo," and Cabeza de Vaca crossed it about 1530; but neither of them recognized its importance.

The fate of this expedition discouraged coastal exploration for a time. But the Spaniards in Mexico were already pushing their way up into the heart of the continent. In 1539 Marcos de Niza, a priest, penetrated New Mexico and came back with reports of the wealth of Cibola, a name which he applied to seven cities somewhere to the north. These were long supposed to be mythical, but have since been identified as the seven Zuñi villages in New Mexico.

The tale led Vasquez de Coronado to set out in 1540. Part of his expedition he sent by water up the Gulf of California under Hernando d'Alarçon, who discovered the Colorado River and ascended it for 85 leagues. The other part he led overland in the direction of Cibola, which he found and conquered (about lat. 35°); and then on into Kansas to about lat. 40°.

The belt of country bounding Mexico on the north received the name "New Mexico" from Antonio Espejo, an explorer who started north in 1582 with Indian guides to the rescue of three missionaries who had been deserted the previous year. Following the Rio Grande del Norte, he came to Cibola and, after learning that the missionaries had been killed, continued to explore the region, and returned by the river Pecos.

The colonizer of New Mexico was Juan de Oñate. He entered the country in 1597 with 130 families and founded the first capital, San Gabriel (second oldest town in the United States), near Santa Fé. In succeeding years he carried his explorations westward through Arizona, in 1604 following the Gila River to the Gulf of California. The following year he founded Santa Fé.

While this was going on in the interior, other nations were interested in the coast. It must be remembered that Columbus was in search of a western passage to Asia when he came upon America. But the idea did not die. A similar quest brought the Cabots to the shores of North America; and later, as the vast extent of the new country began to be realized, one explorer after another searched the coast for a water route by which to pierce the continent. When at last the waters of the St. Lawrence were found to lead no farther than the Great Lakes, explorers still pushed westward along the tributaries of the Mississippi or attempted to round the continent on the north through the ice-blocked seas.

In 1524 Giovanni da Verrazzano, sent by Francis I. of France, examined the shores from South Carolina to Newfoundland, and wrote to the king the first known description of them. He brought back a theory of an inland sea approaching the Atlantic coast about the middle of the continent; and it was to find this "Sea of Verrazzano," as a possible route to Asia, that the king sent Jacques Cartier in 1534 to the Gulf of St. Lawrence (previously discovered by Jean Denys of Honfleur). In the course of three voyages he explored the St. Lawrence as far as Montreal, believing that he had found the western passage.

Cartier attempted to plant a colony near the site of Quebec; but for many years France's efforts in that line were doomed to failure. Equally unsuccessful were Jean Ribaut, who in 1562 brought over a band of Huguenot colonists to the site of Beaufort, S. C.; and René de Laudonnière, who founded Fort Caroline two years later at the mouth of the St. John's River, Florida. In 1565 Pedro Menendez de Avilés came to colonize Florida for Spain, and massacred the inhabitants of Fort Caroline. Laudonnière escaped to France, but Ribaut (who had just arrived from his second voyage with reinforcements for the colony) was killed while attempting to escape along the coast.

Menendez was the first to establish Spanish rule firmly in Florida. He founded St. Augustine (oldest town in the United States) in 1565, sent a mission to the Rappahannock in 1570, and explored Chesapeake Bay and the Potomac.

England sent out her first colonists to Jamestown, Va., in 1607. Among the number was Capt. John Smith, an indefatigable explorer of the neighboring rivers and Chesapeake Bay.

Another Englishman, Henry Hudson, sent out in 1609 by the Dutch East India Company, explored the coast from Nova Scotia to Chesapeake Bay, and then ascended the Hudson River to Albany. It was during the following year that, in the search for a northwest passage, he discovered the strait and bay that bear his name.

France first gained a foothold in North America through the efforts of Samuel de Champlain. The years 1603–7 he spent in exploring the St. Lawrence and the shores of New England, making the first accurate map of that coast. After he founded Quebec in 1608, he became interested in inland exploration, which twice led him into the United States: In 1609 he set out with 11 men to aid the Hurons against the Iroquois, descended the Richelieu in canoes, portaging part of the way, and pushed on through Lake Champlain to about Crown Point; and again in 1615 he accompanied a great war party of Indians by way of the New York lakes into the heart of the Iroquois country, south of Lake Oneida.

From this time fur-traders and missionaries spread over the country bordering the St. Lawrence and its tributaries, gradually approaching the Mississippi. The Spaniards had not followed up their discovery, failing to understand its importance. Nearly a century after De Soto's journey the French at the north began to have an interest in the Indian traditions regarding the "Great River." About 1635 a trader, Jean Nicollet, was sent to a tribe near the head of Green Bay, Wisconsin. From there he went with Indian guides up the Fox River, portaged to the Wisconsin, and descended that until he came "near the sea," as he reported; probably mistaking the "Great Water" described by the Indians for the sea. By 1658 two other French traders, Radisson and Groseilliers, reached the head of Lake Superior and explored the surrounding country.

When these rumors of a great river to the west reached Frontenac, the governor of Canada, he sent Louis Joliet to explore it in company with Jacques Marquette, a Jesuit. Meeting at St. Ignace, they set out with five men and two canoes, skirted the north shore of Lake Michigan and Green Bay, and ascending the Fox River, were guided by Indians across the portage to the Wisconsin, down which they passed, reaching the Mississippi 17 June. For one month they floated down the great stream, noting the mouths of its tributaries as they passed, until they came to an Indian village opposite the mouth of the Arkansas. By this time they knew that the river emptied into the Gulf of Mexico, and supposing themselves nearer the mouth than they actually were, they turned back through fear of Spaniards, returning by way of the Illinois and the western shore of Lake Michigan, which they reached by portage. Two years later Marquette met his death while attempting to establish a mission on the Illinois. His work among the Indians was taken up by Father Claude Allouez, also a Jesuit, who established several missions and traversed much of the country around lakes Superior and Michigan between 1665 and 1680.

Already another explorer was searching for the Mississippi. Robert Cavalier de La Salle was one of those who had come to Canada in pursuit of the passage to China, and guessed that it lay by way of the Mississippi, which he supposed emptied into the Gulf of California. In 1669 he crossed from Lake Ontario to a branch of the Ohio, and followed that river as far as Louisville. The next year he reached the Illinois from the end of Lake Michigan and explored it for some distance. For years he went back and forth through the region and established trade with the western Indians. In 1680 he sent Louis Hennepin, another Jesuit, with two men down the Illinois to ascend the Mississippi. On the way they were taken prisoners by the Sioux and carried up the great river to the Falls of St. Anthony, which Hennepin named. There they were joined by the famous trader Daniel Greysolon Du Lhut, who for two years had fearlessly explored the region around the end of Lake Superior and the head of the Mississippi. He had just come by way of the St. Croix River from his fort on the site of Duluth, and now joined Hennepin on his return journey by the Wisconsin.

At last, in 1682, La Salle attained his goal. With Henri de Tonty and a large party he reached the Mississippi from the foot of Lake Michigan by way of the Chicago and the Illinois, and descended to its mouth. On 9 April La Salle took possession in the name of King Louis of France and gave the name Louisiana to all territory drained by the Mississippi. After his return he sailed for France and obtained permission to transport colonists to the new province. He reached the Gulf of Mexico, but was unable to find the mouth of the river, and put in at Matagorda Bay. There he built Fort St. Louis, and then started overland to find the Mississippi and reach Canada to obtain supplies for the colonists, but was murdered by one of his men near a fork of Trinity River, Texas.

Where La Salle had failed, Pierre Le Moyne d'Iberville was to succeed. In 1699 he entered the Gulf of Mexico and explored the region around the mouth of the Mississippi, leaving a colony at Biloxi, which was afterward transferred to Mobile. With him was one already known as an explorer of the northern region, Pierre Le Sueur. He in 1695 had discovered and named the St. Peter (the Minnesota) River and observed a quantity of green earth near it; and now, in the belief that it was copper, he led a party of men up the river to work it and established a fort on the Blue Earth (Green) River.

Just at this time (1703) Baron La Hontan, a man who participated in many explorations in the north of the Valley, published an account of his wanderings which contains some valuable information with much that is false. He claimed to have discovered a river (La Rivière Longue) entering the Mississippi from the west near Lake Pepin, and to have followed it to its source in a large lake at the foot of mountains, on the other side of which was another river which emptied into the Pacific. This figured on maps for years before it was found to be fictitious.

The right to "farm out" this great country of Louisiana was granted to Antoine Crozat in 1714, and agents were immediately despatched to explore the tributaries of the Mississippi. Before the year was out St. Denis followed the Red River and crossed to the Rio Grande, where he came upon a Spanish mission and was imprisoned, sent to Mexico, and ordered to return. La Harpe in 1719 pushed up the Red River and across to the Arkansas, reaching lat. 37° 21′. He established a post among the Indians, claimed all this country for France, and defied the Spaniards in a letter to the Spanish governor. The exploration of the Missouri was attempted in 1719 by Du Tisné and followed up to six leagues above Grand River, at the peril of his life among hostile Indians, who attempted in vain to bar his passage.

In this southwestern section of the Valley French intrusion was resented by the Spaniards. Their claim to Texas rested on the exploration of its rivers by Francisco de Urdinola in 1575, and an expedition led across its borders by Hernando del Bisque in 1675. Farther west their control was assured by the work of missionaries. Father Kino, a Jesuit, had entered Arizona as early as 1658, and by 1679 had established five missions and become well acquainted with the country. On one of his expeditions he reached the mouth of the Colorado and discovered that Lower California was a peninsula, not an island, as was supposed.

With the expulsion of the Jesuits in 1767 the missions passed into the hands of the Franciscans, who inaugurated the era of Spanish exploration and settlement in California by a colony at San Diego in 1769. Years before pioneers from the east broke through the mountains and seized upon the country, these missionaries had permeated it and stamped their influence upon it.

Meanwhile the French at the north were every year sending traders and explorers into the interior. For some time they continued to use the routes followed by Marquette through Green Bay and by La Salle up the Chicago, but in 1716 they opened a new one by way of the Wabash, and another in 1720 by way of the Miami. A dispute over boundaries arose between the English and the French. Gov. Spotswood of Virginia urged upon the English the necessity of colonizing the Ohio Valley, and in 1716 made his fantastic ride with the "Knights of the Golden Horseshoe" to see if a way through the mountains could be found. He crossed the Blue Ridge and the Shenandoah Valley, but it was not until 1732 that the first settler, Joist Hite, entered the region.

Other efforts were being made to cross the mountains. When it was learned that the French were winning the allegiance of the Cherokees from the English, Sir Alexander Cuming, a Scotchman, set out in 1730 with a party from Charleston and made a circuit of 500 miles across the mountains, bringing back several Indians in token of renewed faith. In 1736 Col. William Mayo and a party of surveyors followed the Potomac to its springs and discovered a portage to waters flowing into the Monongahela. Another route was opened to the Kanawha, an affluent of the Ohio, in 1744 by Col. James Wood, a well-known frontiersman and explorer. Dr. Thomas Walker in 1748 led an expedition across the Virginia mountains, named Cumberland Gap and River, and made a circuit through West Virginia.

As the country became better known public interest awakened, and in 1748 a number of Virginians formed themselves into the "Ohio Company" for the purpose of colonizing the Ohio Valley. To anticipate them, the governor of Montreal despatched Bienville de Céleron down the Ohio to bury at the mouths of its tributaries plates inscribed with the declaration that all territory drained by those waters belonged to France. In spite of this, the Ohio Company sent out Walker in 1750 to survey lands for settlement. He explored Kentucky, and built the first house in the region now comprised in that State. Christopher Gist was also sent to explore routes to the north, select lands for settlement, and investigate the Indian tribes. He made a circuit of 1,200 miles north to the Scioto and Miami, and then south of the Ohio, visiting all the Ohio tribes, and returning by way of the Licking, Kentucky, and Roanoke rivers. On a second mission in 1751 he discovered a new gap from the Potomac to the Monongahela, and explored the Kanawha.

The next year Gist acted as guide to George Washington when he went as emissary from the governor of Virginia to the French fort at the head of the Ohio to protest against the French occupation of the valley. His mission was fruitless, but he brought back a map of his route: up the Potomac, across the divide, and along the Monongahela and Allegheny to the French fort near Lake Erie.

A most prominent figure in English exploration was George Croghan. Sent out by Pennsylvania in 1750 with the half-breed Montour to win over the Indians through the Ohio valley to the English, he went far and wide, from tribe to tribe, attaining an influence over the Indians which was of invaluable service to the English during the French and Indian war. When peace was declared he was delegated to prepare the Indians for English occupation. Starting from Pittsburg, he followed the Ohio, Wabash and Maumee to Detroit, and reported that the way was open; whereupon the English troops, under Capt. Thomas Stirling, advanced to Fort Chartres and took possession of the country east of the Mississippi.

And now, with English control assured, settlement spread rapidly beyond the Appalachians. Much of the preliminary exploration was made by hunters, trappers, and traders too numerous to mention, were they known. North of the Ohio the country was first settled by Moravian missionaries. Among the southern pioneers, James Smith followed the Kentucky and Tennessee rivers in 1766 and John Finlay explored northern Kentucky in 1767; but most prominent was Daniel Boone. His first venture was made in 1769, when he crossed the Cumberland Gap with James Robertson and spent two years exploring eastern Kentucky and Tennessee. Subsequently these two men took a prominent part in the settlement of this region.

With the advent of the American Revolution exploration received a check; but the expeditions of troops led by George Rodgers Clark into the Ohio basin 1778–9, and by Gen. John Sullivan into western New York were not without geographical value. And in the Indian wars which followed (1790–4) the American expeditions under Harmar, Clark, St. Clair, and Wayne added to knowledge of the Ohio Valley.

During the 17th and 18th centuries, while exploration and settlement had been pushed westward from the Atlantic seaboard over half-way across the continent, the Pacific coast was almost unknown. Balboa had discovered the Pacific at the Isthmus of Panama in 1513, and Cortes had sent several expeditions to the west coast of Mexico (1522–24). The first white man to reach the coast of California was the Spaniard Juan Cabrillo, who in 1542 traced it north as far as Monterey; and after his death the following year his pilot continued to Cape Mendocino. In 1576 the English seaman Drake reached lat. 43° in his coastal exploration. To the north the coast was unknown until Vitus Bering (1741), commanding a Russian expedition, visited it in lat. 60°. His voyage was followed by a swarm of Russian fur-traders, who, following the chain of Aleutian Islands during the latter part of the 18th century, gradually worked their way eastward and eventually reached the mainland of what is now Alaska.

In 1778 came Capt. James Cook, the famous English navigator, surveying the coast from Vancouver Island to the Arctic Ocean in his search for a northeast passage. When the published account of this voyage called attention to the rich fur-trade in the northwest, Americans were among the first to take advantage of it. In 1789 Capt. Robert Gray, of Boston, in the ship Columbia, cruised around the Horn and visited the northwest coast, carried a cargo of furs to China, and returned to Boston by way of the Cape of Good Hope. Thus was the American flag first carried around the world. On a second voyage in 1792 he discovered and explored the lower reaches of the Columbia River. This all-important achievement, besides disclosing an easy route from the western mountains to the sea — thus paving the way for trans-continental exploration — formed the chief basis of our territorial claim to Oregon. When George Vancouver, who was exploring the west coast with two British vessels (1792), learned of the Columbia River through Gray, he sent a boat expedition to investigate it. Afterward he continued northward to extend Cook's explorations on the coast of Alaska and British Columbia.

As yet none had succeeded in finding an overland route to the Pacific north of Mexico. Cabeza de Vaca, in his transcontinental wanderings, had turned to the south when he reached the mountains. A Canadian, Varennes de la Vérendrye, spent many years (1731–49) in the search for a route: at his own expense, for his government refused to back him. With his sons he made extensive explorations west of Hudson Bay, in the course of which he discovered (1731) the Red River and Lake Winnipeg, and his son Pierre penetrated to the forks of the Saskatchewan River (1739). In 1742 the two sons made a perilous journey to the southwest, across the Missouri and on to the Big Horn Mountains.

In the struggle for the Ohio Valley the western route was forgotten for a time. But when that contest was settled the quest was renewed by Jonathan Carver of Connecticut. In 1766 he made his way westward by canoe through the Great Lakes, and by Marquette's route to the Mississippi, which he ascended to the Falls of St. Anthony. He explored the Minnesota River, spent a winter among the Sioux, and in 1767 returned by ascending the Chippewa River and reaching Lake Superior waters by portage. While his journey added little to geographical knowledge, yet it served to awaken interest, and led Richard Whitworth to join Carver in planning a transcontinental expedition, which was unfortunately prevented by the outbreak of the Revolution.

Meanwhile the English fur-trading companies, through the journeys of their agents, had contributed much to geographical knowledge, not only of Canada but of the United States. The Hudson Bay Company, since it obtained its charter in 1670 and established its first post (Fort Rupert) on the great bay from which it took its name, had, in spite of French interference, extended along the shores of the bay and its tributaries. After the English conquest of Canada in 1763 it had a clear field until the appearance in 1783 of a rival "Northwestern Company," made up of Canadian merchants, which operated by the direct route from Montreal to the Great Lakes, and rapidly pushed its control throughout the north and west. Its influence was extended to the west coast by Alexander Mackenzie in a journey (1792–3) from Lake Athabasca up the Peace River and across the Rocky Mountains, the head waters of the Fraser River, and the Coast Range to the coast of British Columbia in the latitude of Queen Charlotte Sound. This was the first time the continent was crossed north of Mexico.

Thomas Jefferson in 1803 induced Congress to make an appropriation for the expenses of a transcontinental exploring expedition, a project that he had entertained for some 20 years. Nominally, Capt. Meriwether Lewis was leader of the party, with Lieut. (generally known as Capt.) William Clark second in command; but in point of fact all action was taken jointly, and the expedition is always known as that of Lewis and Clark. While preparations were under way the purchase of the territory of Louisiana from France gave additional importance to the enterprise. Lewis and Clark, with 43 men, left St. Louis, then a frontier trading-post, in three large boats, pushed their way up the Missouri, and built a fort at the Mandan Village, about 50 miles above the present town of Bismarck, N. D. From this point some of the party were sent back, and in the spring of 1805 the rest continued their voyage up the Missouri with 32 men. At the falls the heavy boats were left, and canoes were constructed to continue the ascent of the river. Near the head of what they named the Jefferson (the western fork of the Missouri) they cached their canoes, and with horses secured from the Indians crossed the Rocky Mountains to the Columbia, which they descended to the mouth, reaching the Pacific in November, 1805. After wintering here the party retraced their steps to the east side of the Rocky Mountains, and there separated; Lewis following the Missouri, while Clark traced the course of the Yellowstone. At the junction the reunited forces continued their rapid down-stream journey, reaching St. Louis in September, 1806. This was not only the most notable exploration ever undertaken by the United States government, but its complete success led to the many others which have followed up to the present day.

The head waters of the Mississippi were explored by Lieut. Zebulon Montgomery Pike, who ascended the river with a party of 20 soldiers in 1805. He reached Leach Lake drainage system and found the region already occupied by the agents of the Northwestern Company. Upon his return in 1806 Pike set out again with 23 men, with the idea of winning the allegiance of the Indians from the Spaniards and establishing an American claim to the region which had long been in dispute between the French and Spaniards. He ascended the Osage River in boats, and crossed overland with horses to the Pawnee villages, where he took up the trail of the Spaniard Malgares, who in the previous year had made an excursion into this region from Mexico at the head of several hundred troops. At the Arkansas Pike detailed Lieut. James Wilkinson to explore that stream to the Mississippi, and continued west with the larger section of the party, arriving in November at that high peak of the Rockies which now bears his name. During the winter, after terrible suffering from cold and hunger, he reached the Rio Grande. The Spanish authorities sent out a large force to capture the little band of explorers, and they were conducted back through what is now known as Texas.

The roving fur-traders were quick to penetrate the regions pioneered by Lewis and Clark and Pike. During the years 1806–9 they extended their excursions well into the Rocky Mountains from the east. In Canada the Northwestern Company, ever active, pushed its outposts westward; and in 1808 one of its agents, Simon Fraser, reached the Pacific at the mouth of the Fraser River.

In 1810 John Jacob Astor, a New York fur-trader, organized a company for the purpose of exploiting the trade on the Pacific slope. A vessel was despatched to the mouth of the Columbia River to establish a post, and an expedition sent overland to follow the Lewis and Clark route. This was the second party to cross the United States to the Pacific. Numbering three boats and sixty men under the leadership of one of the partners, Wilson Price Hunt, it left St. Louis in the late summer of 1810, and pushed its way up the Missouri about 450 miles. Here the party wintered, and in the spring continued by boat to the big bend of the Missouri; then with horses purchased from the Sioux proceeded overland in a southwesterly direction, crossed the Rockies near the head of the Big Horn River, and followed the Snake River Valley to the Columbia. With only a fraction of his large party, and after the most terrible suffering, Hunt reached the mouth of the Columbia in February, 1812, and found Astoria, the post established by the party sent by sea. The American company was only just in time: the previous year David Thompson of the Northwestern Company had portaged across the Rockies from the Saskatchewan to the head waters of the Columbia and followed it to the Pacific, where, much to his disgust, he found the Americans already in possession.

In 1812 David Stuart, with a small party, started eastward from Astoria to make the difficult and hazardous journey to St. Louis. He chose a route to the head waters of the Snake, across the divide to the Green River, a tributary of the Colorado, and across a second divide to the Platte, which he followed to its junction with the Missouri, and continued down stream to St. Louis, arriving in April, 1813, after a journey full of peril and hardship.

In 1814 Astoria passed into the hands of the Northwestern Company, which extended its trade over the entire Columbia River basin, and established posts at various points. The eastern slope of the Rockies was occupied by American traders, with headquarters at St. Louis and posts on the upper Missouri in the Green River Valley.

The government began to realize the importance of exploration. In the hope of discovering the sources of the Red River, a large expedition under Maj. Stephen H. Long left Pittsburg on a small steamer in April, 1819, wintered on the lower Missouri and during the following year made explorations and surveys in the country now included in Arkansas and Missouri. Long was sent again in 1828 to explore the head waters of the Mississippi, which he approached through the wilderness from the Miami River to Lake Michigan, thence to the junction of the Wisconsin and Mississippi, and on to the Minnesota: a difficult route, but lying in a region which had been explored by French pioneers more than a century before.

Still the source of the Mississippi had not been discovered. The head water region, previously visited by Pike, and long the stamping-ground of the fur-trader, had been again explored in 1820 by Gen. Lewis Cass, governor of Michigan, in company with Henry R. Schoolcraft. It was not until 1832 that the source was finally discovered in Lake Itasca by Schoolcraft and Lieut. J. Allen.

Capt. B. L. E. Bonneville, an officer of the U. S. army, in 1832 organized a party of trappers and hunters for the ostensible purpose of taking part in the fur-trade, but more to gratify his own ambition to explore the Far West. He left Fort Osage on the Missouri with 110 men, transporting his supplies by means of wagons, instead of using pack-animals, as all previous parties had done. Following Stuart's route of 20 years before along the valley of the Platte River, he crossed the mountains with his wagon-train and established a post at the head of the Green River. From this point as rendezvous his party scattered out in various directions, he himself exploring the Big Horn and Wind River mountains and extending one journey to the English trading-post on the Columbia. A party sent out by him visited Salt Lake, and continued through to the Spanish settlement of Monterey on the Pacific.

During the years 1833–5 the Rev. Samuel Parker, a zealous missionary, made several hazardous journeys from the Mississippi waters to those of the Columbia. At this time the Hudson Bay Company, which had absorbed its rival, the Northwestern Company, controlled the entire Columbia River basin, and claimed it for England, in spite of the protest of the few American settlers. In 1842 it came to the knowledge of the Americans that the English were making preparations to colonize the region, and it was necessary that the authorities at Washington should be informed at once. For this purpose Dr. Marcus Whitman and A. L. Lovejoy set out in the dead of winter on a journey of 4,000 miles across the continent. They took a southerly route through New Mexico to the Arkansas, and Whitman reached Washington.

In 1841 Lieut. R. E. Johnson of the United States Exploring Expedition, commanded by Charles Wilkes, U. S. N., crossed the Cascade Mountains near Mt. Rainier and, after making an extended journey in the Columbia River Valley, recrossed the Cascades to the coast. A detachment ascended the Willamette and crossed to the Sacramento Valley, which they followed to San Francisco.

With the exception of the Lewis and Clark expedition, the most important exploration of the century was done by Lieut. John C. Frémont, who had gained his first experience while assisting J. N. Nicollet, a French geodesist, employed by the United States government 1836–40, for making surveys in the upper Mississippi basin. In 1842 Frémont, with 25 men, among whom was the famous scout, Kit Carson, made surveys of a region lying between the Missouri River and the Rocky Mountains, along the valleys of the Kansas and Great Platte rivers. In 1843 he was instructed to carry his surveys to the Pacific coast. With a party of 40 men he made his way westward from the junction of the Kansas and Missouri rivers to the head waters of the North Platte, crossed to Green River, and traversing a region long known through the explorations of Bonneville and others, crossed another divide and descended Bear River to Salt Lake, which he explored. From there he went westward to the Snake River, and on to the mouth of the Columbia. After renewing the supply of provisions, Frémont retraced his steps to the Dalles of the Columbia, then turned southward to Klamath Lake, and made a hazardous journey through the Sierras which brought him into California along the valley of the American River, an eastern branch of the Sacramento. Traveling southward, he once more crossed the Sierras in lat. 35°, and returned to St. Louis across the Great Basin region and the Rockies. On his third journey Frémont crossed the Rockies from the head of the Arkansas to the Green River Valley, then continued westward around the southern end of Salt Lake across the Sierras, near where he previously traversed them, and then turned northward along the Sacramento Valley and across the mountains to Klamath Lake. Here he was impelled to turn back by the news of the uprising in California, and converted his exploring party into a military expedition.

The southwest became better known through military operations during the Mexican War, and after its close many expeditions were sent out by the government, under both military and civilian leadership, most of them, however, in regions already explored.

Public interest in the construction of a transcontinental railway led to five extensive expeditions during the years 1852–7: the first exploring along the 32d parallel; the second near the 35th; the third near the 38th and 39th; the fourth near the 41st and 42d; and the fifth near the 47th and 49th. Various military explorations and surveys were carried on west of the Mississippi up to the outbreak of the Civil War.

In 1869 Maj. J. W. Powell made a daring exploration of the Grand Cañon of the Colorado. With only a few men, in small boats, he followed the Green and Colorado rivers from Green River Station to the mouth of the Virgin River. In the next two years he extended this exploration in the Colorado basin under government auspices.

The Pacific railroad surveys practically completed the purely exploratory work of the United States; subsequent investigation was directed to minor details. During the years 1867–79 this work was carried on by various organizations which were created for both geographic and geologic research. Four of them were of especial note: "The Geological Exploration of the 40th Parallel," under Clarence King (King Survey); "United States Geographical and Geological Survey West of the 100th Meridian," under Capt. Geo. M. Wheeler, U. S. A. (Wheeler Survey); "United States Geological and Geographical Survey of Territories," under F. V. Hayden (Hayden Survey); "Geological and Geographical Survey of the Rocky Mountain Region," under J. W. Powell. In 1879 the United States Geological Survey was created for this purpose and the other organizations discontinued.

The acquisition of Alaska in 1867 gave American explorers a new field. This territory, occupying the northwest corner of the continent, is peninsular in form, its southern seaboard fronting on the Pacific. An almost unbroken system of mountains lies near the southern coast, forming a barrier which long prevented inland exploration. The broad, depressed interior area behind this mountain system is also cut off on the north and east by another range (the Rockies), which interposed a barrier between the interior of Alaska and that extensive system of waterways of northern Canada which was used by the explorer and fur-trader from the Atlantic coast. The central region opens out to Bering Sea, into which it pours most of its drainage through two great rivers, the Yukon and Kuskokwim: both navigable and affording easy access to the interior.

Alaska had been known to Russians since Bering's discoveries (1724 and 1741) and its coast-line had been explored by Russian fur-traders and naval officers, but more effectively by the English navigators, Cook (1778) and Vancouver (1793). The general shore-survey was continued by Otto von Kotzebue (German in Russian employ) in 1815, and by the English explorers, Sir John Franklin and Capt. F. W. Beechey (1826), Peter Warren Dease and Thomas Simpson (1837). The years 1849–53 saw a confirmation of the coastal exploration by Capts. Thomas E. L. Moore, Henry Kellett, Richard Collinson, and Commander Robert S. McClure, all H. M. S., and belonging to vessels of the Franklin relief expeditions.

In 1864–6 Robert Kennicott, Wm. H. Dall, and others of the Western Union Telegraph Survey, which had for its purpose the establishment of a telegraph line from the United States to Asia via Bering Strait, made explorations in the lower Yukon basin and ascended the full length of the river, about 1,800 miles. It had been traced from the sea for about 1,000 miles (1842–3) by Lieut. Zagoskin, and the Hudson Bay traders had reached it from the east in 1848 and established posts.

At the time of Alaska's transfer to the United States the coast-line had been explored practically throughout, but little was known of the interior; and for many years thereafter no official exploration was undertaken. Capt. R. W. Raymond, U. S. A., ascended the Yukon for 1,200 miles in 1869, but his journey was of no geographic importance. The pioneer fur-traders, among whom may be mentioned Jack McQueston, Arthur Harper, Fred Hunt, Joe Ladue, and Frank Densmore, made many hazardous journeys by which they extended geographic knowledge. Some time in the early seventies George Holt, a prospector, the forerunner of the great multitude to follow, made his way inland by way of the Chilkoot Pass and Lewes River; and by 1883, when Lieut. Frederick Schwatka, U. S. A., followed the same route, it had already become well established among miners and prospectors. In 1885 Lieut. Henry T. Allen made an exploration of the Copper, Tanana, and Koyukuk Rivers. Northern Alaska was explored (1883–6) by Lieut. George M. Stoney, U. S. N., and Lieut. John C. Cantwell and S. B. McLenigan, R. M. S. These expeditions mapped the Noatak, Kobuk, and upper Colville rivers, and Ensign W. L. Howard of the Stoney party extended the work through to the north Arctic coast. The journey of J. H. Turner, U. S. Coast and Geodetic Survey, in 1890 from the Porcupine River to the Arctic coast added to knowledge of northern Alaska. In 1890 E. J. Glave and Jack Dalton explored the Alsek River, which finds its way to the sea through the St. Elias Range. An exploration from the Yukon up the White River Valley to the Copper River was made in 1891 by Lieut. Schwatka in company with C. Willard Hayes, U. S. Geological Survey.

In 1898 the U. S. Geological Survey took up systematic surveys and explorations in Alaska. The first year George H. Eldridge and Robert Muldrow explored the Sushitna Valley; J. E. Spurr and W. S. Post the Kuskokwim Valley; and Alfred H. Brooks and W. J. Peters the White and Tanana river valleys. In the same year Capt. E. F. Glenn, U. S. A., and W. C. Mendenhall, U. S. G. S., penetrated overland from the head of Cook Inlet to the Tanana River. In 1899 F. C. Schrader and T. G. Gerdine explored the Chandler and Koyukuk valleys, while Peters and Brooks made a journey from Lynn Canal to the Yukon, exploring the northern front of the St. Elias Range. The same year Lieut. J. S. Herron, U. S. A., made an exploration in the upper Kuskokwim basin. Two years later the work in northern Alaska was extended by Schrader and Peters northward from the Koyukuk through to the mouth of the Colville, and by W. C. Mendenhall and D. L. Reaburn from the Yukon to Kotzebue Sound by way of the Kobuk River. In 1902 Brooks and Reaburn made an exploration from Cook Inlet through the Alaskan Range, along its northern base by the foot of Mt. McKinley, to the Yukon River.

In spite of all this activity, there are large areas of Alaska which have yet to be explored.

ALFRED H. BROOKS,
United States Geological Survey.

Exploration in the 19th Century. Two phases of geographic research distinguished the 19th century from its predecessors. The largest discoveries of the 18th century were made by sailors — Cook, Carteret, Bougainville, Vancouver, and many others — who brought to light the myriad islands of the oceans or delineated unexplored parts of coast-lines. The largest discoveries of the 19th century, on the other hand, were made in the interior of the great land masses. It was the era of the study of the continents. The Cossack pioneers, in Russia's service, had crossed Siberia, but with this exception not a line of exploration had been run across Asia since Marco Polo in the 13th century till the second half of the 19th century brought forth its scores of Asian explorers. Nearly all our knowledge of the interior of Africa, Australia, and the larger part of North America is also the work of that century.

When Alexander von Humboldt described the travels which he began in South America in July 1799, he ushered in a new era of exploration; for he taught geographers that exploration does not consist merely of topographic delineation of mountains, rivers, plains, and settlements, but that it includes many other factors that have a bearing upon human interests — such as meteorology, climatology, the distribution of plants, and the nature of soils. He was the main pioneer influence in substituting scientific for superficial and unskilled exploration. Thus the 19th century was not only the greatest century in the study of the land surface of the earth, but also in scientific discovery.

South America, Africa, and Australia.— In their exploration, South America is the anomaly and Africa the wonder among the continents. South America is the only great region whose exploration on a large scale quickly followed European occupancy. The Amazon was known almost from its sources to its mouth, in the middle of the 16th century. Nearly all the coast cities on our maps were founded at that time, and a little later the Jesuits established their almost independent states in the heart of the continent; but to-day South America lags behind them all. Inner Africa, the geographical enigma 50 years ago, is better known. No railroad in Brazil penetrates so far inland as the African railroad to Matabeleland. South America is the part of the habitable world where most pioneer exploration remains to be done.

These facts are mainly the result of one potent influence that enabled the 19th century to contribute most largely to detailed geographical knowledge. It was the desire of the European powers to acquire more lands, widen commerce, and spread civilization that, in the past 50 years, has placed in the field scores of very costly exploring enterprises, many on a military basis, and fitted for really scientific work on a scale far beyond the scope of private achievement. South America has been outside this field of rivalry. Her days of largest exploration were when Spain and Portugal were great colonial powers. But early in the 19th century they lost that continent; and the republics which succeeded them, poor in purse and involved in many civil and external wars, have scarcely made the exploration of their own territories a state affair until within the past few years. The world knows far more of inner Africa to-day than the government at Bogota knows of the southeastern third of Colombia. Dr. Sievers has mentioned the fact that long series of meteorological observations in inner Africa are now available, while in large parts of South America — as in the llanos of Venezuela and most of the Amazon basin — there are no records of value for scientific deductions with regard to climate. .

But the European nations did not enter upon this great task of studying the undeveloped continents till they received the impulse from the humble pioneers of discovery. Stanley says he thought Livingstone was an enthusiast and a visionary when they stood together on the shore of Tanganyika, and the great missionary-explorer, with uplifted hand trembling with weakness, told him the day was coming when the civilized nations would see the good in Africa and set about the reclamation of the continent. It was Livingstone, first of all, and his successors, who started the movement, which gathered volume and momentum till we see a continent one third larger than our own parceled out among the European powers, which have practically completed exploration on broad lines, and are studying it in detail.

Twenty years ago the country back of the west coast of Australia was an unknown Sahara, through which only three or four travelers, at the risk of their lives, had pushed their way. Then it was discovered that this frightful waste was the treasure-house of western Australia, guarded from all intruders by thirst and famine. The entire topography of this spinifex-covered desert has now been revealed. This exploration was made possible by the fact that the great modern agent of civilization, the railroad, was pushed out into the desert at various points, so that thousands of men, with supplies daily replenished from the coast, may live there and find and develop the gold resources. This illustrates the fact that many inventions of the 19th century which facilitate the development of little-known lands have stimulated the work of discovery because they have made it easier to obtain substantial results for business as well as for science by exploratory enterprises.

Better Knowledge of Our Own Country.— The text-books which our school children used 100 years ago told them nothing of the Rocky Mountains or of the ranges of the Pacific slope. The exploration of three fourths of our vast domain has been the work of our government and private citizens. In a broad sense, it has been well done; and in the past 25 years it has been succeeded by detailed studies and surveys which should be specially mentioned, for they are a phase of exploration never carried out on a large scale till the 19th century, and which is essential to the production of the most accurate maps. No topographic feature or town or distribution of economic resources can be mapped with the greatest attainable accuracy till these surveys are made. They involve, (1) The preparation of a topographic map showing the relief or inequalities of the surface, the drainage, and the works of man, such as roads, railroads, boundaries, and towns; (2) the geologic map, printed in colors upon the topographic base map, showing the distribution of the rock formations, soils, useful minerals, artesian waters, etc. These surveys and the resulting maps are one of the most scientific developments of geographic research in the 19th century. They have been completed in all countries of Europe except in Norway, Spain, Turkey, and some of the Balkan states. The great survey of India is one of the monuments of cartography, and similar surveys are far advanced in Algeria and Tunis. The topographic work has been carried by our general government, with the assistance of a few states, into all the States and Territories, and about a third of our entire area has now been completed. The labor is enormous and costly, and many years will elapse before the whole country can be mapped with the refinement and accuracy that characterize the map sheets of the most of Europe.

Mapping the Ocean.— Oceanography, one of the largest departments of geographic science, may be said to be wholly a development of the 19th century. It was not known before that the sea-bottom, like the land, has its mountains, valleys, and plateaus. It was believed that life could not exist at depths below 1,500 feet; but we now know there are forms of life at the bottom of the deepest oceans. Ingenious appliances have been invented for exploring the depths of the sea, and the world has to-day a general idea of the contour of the ocean floor, and of the conditions of movement, temperature, salinity, and life that prevail at different sea-depths. Nearly all these additions to knowledge have been made in the last 50 years. The science of limnology is not 30 years old. This is the study of lakes, their depths, color, transparency, life, and other characteristics. It has been widely pursued in Switzerland, France, and Germany, and, to some extent, in other countries.

Blank Spaces on the Map.— The whole of North America south of subarctic latitudes has now been carefully explored, and the 13 large areas in northern British America, to which Dr. Dawson referred as unknown, not many years ago, have passed out of that category or been greatly reduced in size by such work as Ogilvie has done on the upper Yukon, Low in Labrador, and the Tyrrell brothers in the Barren Lands. Next to Europe, North America is the best-explored part of the world, though 60 years ago more than half the continent was not so well known as most of Africa is to-day. It is only a question of time when all the habitable territory of the United States and Canada will be as thoroughly studied and mapped as that of the European states.

Central America still offers a large field to the explorer. The long, gentle slopes from the central mountains to the eastern coasts, continually drenched by the trade-wind rains, have a luxuriant and almost impenetrable vegetation, and are still very little known. It is on the drier Pacific side of these little states that development is mainly centred.

Most of the additions the 19th century made to South American exploration were the work of European and North American explorers, many of them poorly equipped and paying their own way. Their most conspicuous service has been the mapping of the drainage and explorations in the northern and central parts of the

Cordilleras. The Spaniards long ago revealed the courses of the Amazon and La Plata-Paraguay, but they paid little attention to smaller streams and tributaries. It was left to the 19th century, and particularly to its last three decades, to explore these rivers, and we now have an excellent idea of all the large features of the drainage system. European explorers have made Ecuador better known than Colombia simply because they have been attracted to the Ecuadorian Andes as a specially inviting field. Political or military influences have mainly incited exploration so far as the states have participated in it. Thus the important wars that Argentina waged in 1879–80 with the Indians of the south, and in 1884–5 with those of the north, had the incidental result of making large parts of Patagonia and the Gran Chaco fairly well known.

Explorations in South America.— When Chile and Argentina based their boundary treaty of 1881 upon inaccurate geographical knowledge they sowed the seeds of an international quarrel. The result was that both began to survey the Cordilleran regions in dispute, and the resulting maps of the entire Andean Territory between Cape Horn and lat. 39° S. are specimens of excellent survey work, and have revealed a hitherto unknown region. Explorations in South America are of very uneven merit. Many are only crude route surveys. Argentina is by far the best-mapped country for its geological and meteorological departments, and the staff of foreign professors in the higher schools placed exploration and mapping, after 1882, on a high plane. The Brazilian government has never promoted scientific exploration, and all official work in that line has been done by a few states, mainly by Minas Geraes, São Paulo, and Pará. Most of the far interior, away from the rivers, is still unknown. The Amazon basin is one of the largest unexplored areas in the world; for, though steamers sail regularly on the main stream and many tributaries, the stretches between the rivers have not been visited. The inland parts of the Guianas and of the cordilleran countries from Venezuela to Bolivia are still in the crude and early stages of exploration.

What a contrast Africa presents! A hundred years ago the world had knowledge only of its coasts, Egypt, some of the Barbary Coast lands, bits of Senegambia, and the upper Niger, revealed by Mungo Park, and the Cape of Good Hope for 120 miles inland. All the rest was a blank on the maps. The last inhabited area of importance that was wholly unknown a few years ago, that between Lake Rudolf and the Nile, has been crossed by the American explorer, Dr. Donaldson Smith. The least-known part of Africa is now the Sahara and Libyan deserts, which have been neglected, on the whole, though a great deal has been done to reveal their character. This neglect is due partly to the small economic importance of these regions, but mainly to the hostility of the natives.

Pioneer Exploring in Asia.— Nearly three quarters of a century ago it was said before the British Association: «We have only a general knowledge of the geographical character of the Burman, Chinese, and Japanese empires; the innumerable islands of the latter are still, except occasionally, inaccessible to European navigators. Geographers hardly venture on the most loose description of Tibet, Mongolia, or Chinese Tartary, Siam and Cochin-China.» Since that time a swarm of explorers have overrun nearly every portion of Asia. India is as well mapped as any part of Europe, and that great survey is now being extended over Burma. Japan is mapping her own rugged islands by the most detailed and scientific methods. There are only two regions in that largest of all the continents where pioneer exploring may now be done. One of them is in central and southern Arabia, where there are still large areas, probably sandy desert, that are wholly unknown. The other is in Tibet, the highest of plateau regions, where there are large gaps to be visited between the lines of exploration run by many Russian, British, and French explorers and the American, Rockhill. Thus the era of running route surveys in Asia was closing with the end of the 19th century, and the work of detailed exploration, completed in India, is now rapidly extending.

Our knowledge of Australia, like that of Africa, is the gift of the 19th century. A number of explorers, of whom the best known was Dr. Leichardt, have perished in the waterless and repellent waste that covers the vast interior. But this sandy desert is now marked in all directions by the tracks of explorers; and one of the most practical features of their work was the discovery, around the desert margins, of wide areas of grazing lands that are making Australia one of the greatest of stock-raising countries. The interior of eastern New Guinea, the largest island except Greenland, has been opened to our knowledge within the past 20 years by the British and Germans, who wished to ascertain the nature of their new possessions. The fact that the western half of the island is still almost unknown seems to show that its masters, the Dutch, have lost the zeal that placed their fathers among the hardiest and most enthusiastic explorers.

Polar Explorations.— In Polar exploration, the 19th century scarcely excelled the splendid achievements of earlier ages, though it added many new islands to the maps, attained the farthest north, and, what is perhaps most important, perfected the art of living and traveling, in comparative safety, in the high latitudes. It may be that the archipelago north of this continent will be considerably extended by later explorations, but there are good reasons for believing that the still unknown Arctic area contains no great land masses. The unknown part of the Antarctic regions is twice as large as Europe, and contains the largest unexplored area in the world. Already the present century has entered upon explorations in that quarter which promise important results. Every Arctic expert now believes that the attainment of the North Pole is only a question of time; and it is probable that the 20th century will fully complete the pioneer exploration of the entire world, which the 19th century so wonderfully advanced.

Cyrus C. Adams,
Fellow of the American Geographical Society.

Explosion, a sudden bursting, generally due to the rapid production of gaseous matter from solids or liquids. Thus the explosion of gunpowder is due to the sudden formation and expansion of gases into which the powder is converted by chemical agency. Explosions are often caused by the elastic force of steam confined in boilers, and by spontaneous combustion. See EXPLOSIVES.

Explosive Gelatine, blasting gelatine or gum dynamite, an explosive material resembling wine jelly in appearance. It was invented by Nobel in 1878, and consists of soluble cellulose nitrate dissolved in nitroglycerin. Originally, the solution was effected by warming the nitroglycerin and adding the perfectly dry soluble cellulose nitrate, called nitro-cotton, little by little, with stirring, whereby the nitroglycerin was made to dissolve from 4 to 10 per cent of the nitro-cotton: Then the solution was effected by the aid of a solvent like acetone, which was afterward evaporated off. All of these processes of manufacture were dangerous. In 1889, Lundholm and Sayer discovered that if the nitroglycerin and nitro-cotton are mixed with warm water and stirred up by compressed air, gelatinization sets in, and may be completed by pressing out the water and working the mass in malaxating machines. Explosive gelatine is a gelatinous mass, looking something like new honey in color, and varying in consistency from a tough leather-like material to a soft jelly, in accordance with a variety of circumstances, such as the quantity and chemical composition of the nitro-cotton used, and the methods of manufacture. In general, the thinner the gelatine, the more sensitive it is to detonation; but, on the other hand, a thin gelatine is more subject to liquefaction and possibly also to exudation, which would make it dangerous in storage, transportation and use. Specially strong detonators are required to explode blasting gelatine; or else ordinary detonators together with primers of dynamite or gunpowder. In order that detonation should be transmitted through a mass of explosive gelatine it must be confined; for, unlike dynamite, a train of it cannot be exploded in the open, except by means of an extremely powerful initial detonation. The sensitiveness of the material is still further diminished by the solution in it of camphor, or other substances rich in carbon and hydrogen, like benzine or nitro-benzine. Explosive gelatine containing camphor has been proposed for use as a bursting charge for high explosive shell, under the name of "military explosive gelatine." While dynamite and nitroglycerin when frozen are much less liable to be exploded by a blow, such as that given by a rifle bullet, the reverse is true of frozen explosive gelatine. Though while in the unfrozen condition explosive gelatine is less sensitive to shock or blows than either nitroglycerin or nitrocellulose, it is, when exploded, a more powerful explosive than either of them. This is due to the fact that when nitroglycerin is detonated, there are unused oxidizing materials in the gaseous products; and when cellulose nitrate is detonated, there are unused combustible materials in the products. When, therefore, these bodies are mixed in the right proportions, the products will be those of complete combustion. Explosive gelatine has the advantage over dynamite in that it is practically unaffected by water and therefore can be stored in water. It is, on the whole, less liable to freeze than dynamite. It possesses an advantage over guncotton, in being plastic and can, therefore, better adapt itself to the irregularities of the bore-holes in loading. The specific gravity of explosive gelatine is from 1.5 to 1.6. If heated slowly, beginning at 60° C., it will explode at 204° C. (399.2° F.). On rapid heating it explodes at 240° C. (464° F.). If ignited when frozen even small quantities may explode. Pure explosive gelatine is never used excepting either for blasting in unusually tough rock or for blasting under water, or for military purposes. It is put up in cylindrical "sticks" in paper wrappers like dynamite. For general use in blasting it is too violent, and therefore "gelatine dynamites" are made by mixing this costly and powerful material with diluents. A great many different dopes are used, but a good example of a gelatine dynamite is "gelignite," which is made by mixing 65 per cent of explosive gelatine with 35 per cent of an explosive wood-pulp dope, giving a substance consisting of nitroglycerin 62.5 per cent, nitro-cotton 2.5 per cent, sodium nitrate 26.25 per cent, wood pulp 8.4 per cent, and sodium carbonate 0.35 per cent. It is interesting to note that "ballisti," which is a smokeless powder, is also made by dissolving nitro-cotton in nitroglycerin, but while explosive gelatine contains at the most but 10 per cent of nitro-cotton ballistite contains 40 per cent of this material.

Explosives (from Lat. *explosus,* p.p. of *explodere,* to drive out, to drive out a player with clapping, to explode; from *ex,* out + *plaudere, plodere,* to clap, strike, applaud), are substances which easily react at comparatively low temperatures with the formation of a considerable volume of highly expanded gas, the evolution of heat and light and the production of sound. At ordinary temperatures they may be solid bodies like gunpowder or liquid like nitroglycerin or gaseous like fire damp mixtures. They may consist wholly of a single chemical compound like mercuric fulminate, or of mixtures of combustible substances with supporters of combustion or oxidizing agents like blasting powder, which is a mixture of charcoal, sulphur, and sodium nitrate. Though the temperature is different for each explosive they can all be caused to explode if heated to the explosion temperature, which for nitrogen chloride is 93° C.; mercuric fulminate, 152° C.; emmensite, 165° C.; nitrostarch, 175° C.; dynamite, guncotton, and nitroglycerin each, 180° C.; blasting gelatine, 204° C.; blasting powder, 270° C.; picric powder, 273° C.; rifle powder, 275° C.; best sporting powder, 315° C.

History.— The inventor of gunpowder, the oldest of explosives, and the place where it originated, are not known. The invention has been ascribed by different authors to Marcus Græcus, Albertus Magnus, Roger Bacon, and Berthold Schwarz; to the Arabians, whose works were largely used by Marcus Græcus in his writings; to the Hindus, because of certain passages occurring in the code of Gentoo laws prepared by Indian savants by order of Warren Hastings in the 18th century; and to the Chinese because of certain statements made by Marco Polo. There seems to be little doubt that this confusion exists (1) because modern meanings have been given to words and phrases used in the old manuscripts; (2) because of the intentionally confusing methods employed by the writers of the Middle Ages; and (3) because gunpowder for use in guns was not the invention of any one person, but was really the result of a progressive development.

It is recorded that what moderns call "Greek fire," and the ancients called "naphtha," was employed in the defense of Constantinople in the 7th century and that these fiery compositions were propelled against the enemy by means of arrows from bows, or in hollow vessels of stone or iron thrown by war engines. Though consisting at first of pitch, rosin, sulphur, and similar easily inflammable and highly combustible substances, it is easy to imagine that in the tentative development of these materials of war nitre was added to the combustible substances and that there was thus produced a deflagrating composition for use as bursting charges in bombs and grenades and for the manufacture of devices analogous to modern firecrackers and rockets with which to frighten and confuse their foes.

The supposition that gunpowder was known before it was applied for use in guns is supported by the older historians. All the components and mixtures for Greek fire similar to gunpowder were already known in the time of Hassan-al-Rammah (1290). From an exhaustive search of the literature Guttmann arrives at the conclusion "that gunpowder was gradually developed from Greek fire, and that it was known for years before cannons and guns were thought of. The use of purer materials in making it developed its propulsive power, and led to the subsequent invention of cannons and guns. The Arabians were the first to make gunpowder-like mixtures, probably about 1280 A.D., while the idea of utilizing their propulsive force, that is, the invention of guns and cannons, belongs to the monk, Berthold Schwarz, of Freiburg, Saxony; the date of the latter invention being probably 1313 A.D." It is accepted as indisputable that gunpowder mills existed at Augsburg, Germany, 1340, and at Spandau, Germany, 1344, and that the English used gunpowder in guns at the battle of Crécy, 1346.

Though many improvements were made in the manufacture of gunpowder, such as in the preparation and purification of the raw materials from which it was produced; the methods of incorporation; and its granulation to adapt it to special uses, this substance remained unrivaled until the end of the 17th century, when the French chemist, Berthollet proposed the substitution of potassium chlorate for the potassium nitrate and produced by this means a much stronger and quicker powder, but one which was also much more dangerous than gunpowder. Beginning with the discovery of mercuric fulminate by Howard, an English chemist, 1880, there was added to the achievements of the 19th century the discovery of nitrogen chloride by the French chemist Dulong, 1812; nitrostarch by Braconnot, 1832; guncotton by Schoenbein of Basel, Switzerland, 1845; nitroglycerin by Sobrero at Turin, Italy, 1846; the invention of blasting powder by L. DuPont of Wilmington, Del., 1856; the discovery of diazo compounds by the German chemist, Griess, 1860; the invention of dynamite by A. Nobel of Sweden, 1866; smokeless sporting powder by Schultze of Potsdam, Germany, 1867; blasting gelatine by Nobel, 1878; military smokeless powder by Vieille of France, 1886; hard-grained smokeless sporting powder by Richard von Freeden of Walsrode, Germany, 1889; homogeneous smokeless powder composed of a single chemical substance in a state of chemical purity by Charles E. Munroe of Newport, R. I., 1890; and the discovery of triazoic acid by Curtius of Kiel, Germany, 1890, while in the meantime picric acid, which was discovered by Hausmann, 1788, was shown to possess explosive properties and adapted for use in shell, it having been pointed out by Sprengel, 1873, that it contains a sufficient amount of available oxygen to render it, without the help of foreign oxidizers, a powerful explosive when fired with a detonator.

This growth has been coincident with the development of the chemical and physical sciences and has been the more rapid, the more completely experimental methods of research have been perfected and applied. In addition to those enumerated above this advance in the science and art of explosives has been chiefly due to the labors and intelligence of Hess, Lauer, Trauzl, and von Lenk in Austria; Abel, Cundill, Debus, Dewar, Dixon, Dupré, Majendie, and Noble in England; Berthelot, Chalon, Daniel, Desortiaux, Gay-Lussac, Lavoisier, Le Chatelier, Mallard, Maurouard, Roux, Sarrau, Turpin, and Violette in France; Bunsen, Dittmar, Guttmann, Liebig, Meyer, Schischkoff, Upmann, Will, von Förster, and von Romocki in Germany; Abbot, Barnard, Craig, Emmens, Judson, Hill, Maxim (q.v.), Mixter, Mowbray, Quinan, Rodman, Count Rumford, and Woodbridge in the United States; Mendeléeff in Russia; Cronquist in Sweden, and Hebler and Lunge in Switzerland. Because of their prominence in this science Abel and Berthelot deserve special mention.

Sir Frederic Augustus Abel, K.C.B., D.C.L., chemist, was born in London 1827 and died 6 Sept. 1902. He was tutor to Edward VII., the present king of England; professor of chemistry at Woolwich 1851; chemist to the war office 1854–88; chairman Government Committee on Explosives 1888; member of Royal Commission on Accidents in Mines; president of the London Chemical Society, Society of Chemical Industry, Institute of Chemistry, Institute of Electrical Engineers, Iron and Steel Institute, and of the British Association for the Advancement of Science; he perfected the manufacture of guncotton, making it a valuable explosive; conducted with Capt. Nobel elaborate researches on fired gunpowder; together with Prof. Dewar invented the smokeless powder, known as cordite, which was adopted and used by the British government; and was the chief authority in the United Kingdom on explosives and explosions. Among his published works may be cited: 'Guncotton' (1866); 'The Modern History of Gunpowder' (1866); 'On Explosive Agents' (1872); 'Researches on Explosives' (1875); 'Electricity as Applied to Explosive Purposes' (1884).

Marcellin Pierre Eugène Berthelot, chemist, was born in Paris 25 Oct. 1827, and has been professor of chemistry in the Collège de France since 1865; member of the Institute 1873, perpetual secretary of the Academy of Sciences 1889; inspector-general of higher education 1876; life member of senate 1881; minister of public instruction 1886–7; minister of foreign affairs 1895–6; he has achieved equal fame for his researches, discoveries, and philosophical deductions in synthetic chemistry, thermochemistry, explosives, and historical chemistry. Among his published writings may be cited: 'Chimie Organique Fondée sur la Synthèse' (1860); 'Mecanique Chimique Fondée sur la Thermochimie' (1879); 'Les Origines de l'Alchimie' (1885); 'Sur la Force de la Poudre et les Matières Explosives' (1871, 1872, and 2 vols. 1879). The last was translated into English, 'Explosives and Their Power' (1892).

Theory of Explosives.— When wood or other combustible substances containing hydrogen and carbon are ignited in contact with air they burn, giving forth heat and light and are converted into water and carbon dioxide, which pass off as invisible and highly expanded gases. As the wood is subdivided so as to expose a continually increased surface to the air the rapidity of the combustion is increased until, when the wood is reduced to dust like sawdust and suspended in the air so as to be intimately mixed with it, the velocity of the combustion is so great and the evolution of the gases so rapid that the reaction becomes an explosive one and such a mixture of sawdust and air is an explosive. All inexplosive combustible substances can, when finely divided and intimately mixed with air, form explosives, and volatile liquids and gases are especially likely to do so. Many accidents have arisen from the ignition of mixtures of air with the dust of charcoal, coal, flour, malt, soap, starch, sugar, zinc, wood, and other solids; with the vapors of alcohol, ether, gasoline, and other naphthas, spirits of turpentine and other liquids, or gases like acetylene, coal gas, hydrogen, and marsh gas since each of these substances, though in themselves non-explosive, form explosive mixtures with air if they be mixed with it in the right proportions. The best proportions are those in which the volume of oxygen in the air present is just sufficient to convert all of the hydrogen in the combustible into water and all of the carbon into carbon dioxide, or, in other words, to produce complete combustion. Less violent explosions may occur when the proportion of air is greater or less than the "best proportion," the limit being fixed in each case by the character of the combustible substance, the quantity of the mixture, the temperature and pressure to which it is subjected and the manner in which it is ignited. Mixtures of these substances whose proportions are outside of these limits may be ignited and may burn, but do not explode.

If pure oxygen in the proper proportions be substituted for air in the above mixture the velocity of the reactions will be still greater, and the energy set free in unit of time and consequently the violence of the explosion will be greatly increased. Besides the proportions that determine the limits between explosion and combustion will be extended. Such mixtures if confined and out of contact with the air will still take fire and explode. Oxygen may be supplied either in the free state or in solid bodies which contain it and which give it up when heated to comparatively low temperatures. Among such solids are the nitrates of metallic radicles, like ammonium nitrate, potassium nitrate (India saltpetre), and sodium nitrate (Chile saltpetre); chlorates such as potassium chlorate; peroxides like sodium peroxide, and many others. If these solids be dried, finely divided, and intimately mixed with a combustible, in the right proportions, a solid explosive is produced. Often, as in the case of mixtures of charcoal and saltpetre the temperature to which they must be heated in order that combustion shall begin, called the point of ignition, is so high that they are difficult to ignite and in such cases a small portion of a substance like sulphur, which has a low point of ignition, is incorporated in the mixture.

Another method by which oxygen may be brought into intimate contact with combustible bodies so as to form an explosive is through the action of nitric acid upon them. Two cases present themselves. First when the combustible body is a simple or mixed primary alcohol and the nitric acid reacts with the acidic hydrogen. Second, when the combustible substance is a hydrocarbon or its derivative and the nitric acid reacts with the hydrogen of the hydrocarbon or the hydrocarbon nucleus. The products of the first case are organic nitrates called also nitric esters. The products of the second case are nitro-substitution compounds. Examples of the first case are ethyl nitrate from ethyl or grain alcohol, glycol nitrate from ethylene glycol, glyceryl nitrate (nitroglycerin) from glycerol (glycerin), mannitol nitrate from mannitol (mannite), starch nitrate (nitrostarch) from starch, and cellulose nitrates (guncotton and pyroxylin) from cotton. Examples of the second case are mono and di nitro benzene from benzene, tri nitro phenol (picric acid) from carbolic acid (phenol), and nitro-naphthalenes from naphthalene. These explosives differ markedly from mixtures like gunpowder, for, whereas in the mixtures the combustible substance and the oxidizing agents are in different masses, in the explosive compounds like nitroglycerin, they are both in the same molecule. Therefore in the latter the contact is more intimate and the reaction takes place with greater velocity.

In addition to the explosives of the characters lescribed above is another class of chemical compounds, of which mercuric fulminate, silver amine (fulminating silver) and diazo benzene nitrate are notable examples, whose explosive properties are due to a phenomenon (namely, a molecular disruption), which is quite unlike that of combustion ascribed to those of the previous classes. This case of disruption arises from the fact that these substances are endothermous compounds, or in other words, that they absorb heat during their formation and are therefore reservoirs of energy.

Classification of Explosives.— Following the foregoing theories of their constitution and behavior, explosives may be classed as

(1) *Nitrate mixtures.*— Amide powder (charcoal, potassium nitrate, and ammonium nitrate); amidogene (bran or starch, charcoal, magnesium sulphate, potassium nitrate, and sulphur); azotine (petroleum, charcoal, sodium nitrate, and sulphur); blasting powder (charcoal, sodium nitrate, and sulphur); carbazotine (bark or wood pulp, lampblack, ferrous sulphate, potassium nitrate, and sulphur); Courteille's triumph safety powder (charcoal, peat, coal, oleaginous matters [animal or vegetable], metallic sulphates, sodium nitrate, and sulphur); diorrexine (sawdust, sodium nitrate, potassium nitrate, and sulphur); fractorite (rosin, dextrine, potassium dichromate, ammonium nitrate); gunpowder (charcoal, potassium nitrate, and sulphur); haloxyline (charcoal, sawdust, potassium ferro-

cyanide, and potassium nitrate); Himly's powder (hydrocarbons and potassium nitrate); Nordenfeldt and Meurling's powder (hydrocellulose, potassium nitrate, and sulphur); pyrolithe (charcoal, sawdust, sodium carbonate or sulphate, potassium nitrate, sodium nitrate, and sulphur); saxifragine (charcoal, barium nitrate, and sulphur).

(2) *Chlorate mixtures.*— Asphaline (hydrocarbons, potassium sulphate, potassium nitrate, potassium chlorate); Berthollet's powder (charcoal, potassium chlorate, and sulphur); britainite (naphthalene, potassium nitrate, ammonium nitrate, potassium chlorate); Callow's powder (orpiment, potassium ferrocyanide, and potassium chlorate); carlsonites (naphthalene, or dinitrobenzene, and other combustible substances with ammonium perchlorate); comet powder (rosin and potassium chlorate); cycene (cane sugar, paraffin oil or coal dust, potassium nitrate, and potassium chlorate); Ehrhardt's powder (tannic acid, charcoal, rosin, potassium nitrate, and potassium chlorate); Hahn's powder (charcoal, spermaceti, antimony sulphide, and potassium chlorate); Himly and von Trutschler-Falkenstein's powder (coal tar, potassium nitrate, and potassium chlorate); Horsley's powder (nutgalls and potassium chlorate); Kellow and Short's safety powder (tanbark or sawdust, potassium nitrate, sodium nitrate, potassium chlorate, and sulphur); Knaffl's powder (ammonium ulmate, potassium nitrate, potassium chlorate and sulphur); Melland's paper powder (porous paper which has been soaked in a paste composed of starch, charcoal, potassium ferrocyanide, potassium chromate, potassium nitrate, potassium chlorate, and water and dried); Oriental powder (gum gambier and potassium chlorate); Parone's explosive (carbon disulphide and potassium chlorate); Pertuiset's powder (sulphur and potassium chlorate); pyrodialites (mixtures of coal tar with chlorates or perchlorates and with or without nitrates, nitrosubstitution compounds, charcoal, and oxidizing salts); pyronome (rye flour, charcoal, metallic antimony, sulphur, potassium chromate and potassium chlorate); rossellite (asphalt oil and potassium chlorate); Siemen's powder (a solid hydrocarbon, potassium nitrate, and potassium chlorate); thorite (cane sugar and potassium chlorate); tutonite (metallic sulphides, sulphur and potassium chlorate); and white powders of Augendre and Pohl (cane sugar, potassium ferrocyanide, and potassium chlorate).

(3) *Oxidizing mixtures.*—These are mixtures of combustible substances with oxidizers other than the nitrates, chlorates or perchlorates. Among such bodies may be named sodium peroxide, potassium permanganate, potassium dichromate, liquid air, and liquid nitrogen tetroxide. As examples we have mixtures of sodium thiosulphate with sodium peroxide; metallic aluminum with sodium peroxide; cotton wool with liquid air, and panclastite, which is a mixture of carbon disulphide with liquid nitrogen tetroxide.

(4) *Organic nitrates or nitric esters and mixtures containing them.*— Esters: Guncotton, which is a cellulose nitrate of high nitration and practically insoluble in a mixture of ether and alcohol at ordinary temperatures; nitrocellulose, a term applied to all cellulose nitrates; nitroelectrite (isomannitol nitrate); nitroerythrite (erythrol nitrate); nitroethyl (ethyl nitrate); nitroglucose, a nitrate produced from grape sugar; nitroglycerin, pyroglycerin or glonoin oil (glyceryl trinitrate); nitrolactose (nitrated sugar of milk); nitrolignin (nitrated wood); nitromannite (mannitol nitrate); nitromethyl (methyl nitrate); nitrostarch or xyloidine (starch nitrate); nitrosugar or nitrosaccharose, a nitrate produced from cane sugar; pyroxylin, collodion cotton, nitrocotton or pyrocellulose, are cellulose nitrates of medium nitration and practically completely soluble in a mixture of ether and alcohol at ordinary temperatures. In this class is also to be included the explosive mixtures into which these esters enter as essential components and of which the dynamites are conspicuous examples. These are classified, according to the nature of the *dope* or absorbent, into

A. *Dynamites with an inert base.*— Nobel's dynamite No. 1, giant powder No. 1; dynamite blanche de Paulilles; dynamite de Vonges; E. C. dynamite; S, 1, dynamite; Rutenberg's explosive; dynamite rouge, all consist of nitroglycerin with kieselguhr; Hill's powder (nitroglycerin with precipitated silica); Mowbray's mica powder (nitroglycerin with asbestos); Hercules powder (Extra No. 1); (magnesia powder, nitro-magnite; dynamagnite; fulgurite; nitroglycerin with magnesia alba); dynamite de boghead (nitroglycerin with ashes from Boghead coal); selenitic powder (nitroglycerin with plaster of Paris); Horsley's powder No. 1 (nitroglycerin, alum, and magnesium sulphate); metalline nitroleum (nitroglycerin, red lead, and plaster of Paris); renish dynamite (nitroglycerin, kieselguhr, and naphthalene); dynamite noire (nitroglycerin, sand, and coke); mataziette (nitroglycerin, sand, ochre, charcoal, and resinous matter); porifera nitroleum (nitroglycerin, sponge, or vegetable fibre, and plaster of Paris); Burstenbender's explosive (nitroglycerin, spongy vegetable substances with glycocoll or chondrin); Morse's explosive (nitroglycerin with rosin); Borland's carbo-dynamite (nitroglycerin with charcoal from cork); white dynamite (nitroglycerin with lime-guhr); boritine (nitroglycerin, kieselguhr and boric acid); fluorine (nitroglycerin, kieselguhr, and calcium fluoride).

B. *Dynamites with an active base.*— *a.* Consisting of nitroglycerin absorbed by a gunpowder like dope — Ammonia dynamite; ammonia krut; ammonia powder; Coad's explosive; Champion's powder; colonia powder; Dittmar's powder; dynamite No. 2; dynamite au charbon; dynamite d'ammoniaque; dynamite grieses de Paulilles; extra powder; Fowler's explosive; giant powder No. 2; Gotham's powder; Hercules powder; Horsley's powder No. 2; Judson's powder; Jupiter powder; lithofracteur; Monakay's explosive; miner's powder Co. dynamite; Neptune powder; potentia; petrolithe; sebastine; thunderbolt powder; Titan powder; virite powder; Vulcan powder.

b. Consisting of nitroglycerin absorbed by or gelatinized with a cellulose or ligno-cellulose nitrate — Blasting gelatine; cellulose dynamite; Clark's explosive; Dean's explosive; Dittmar's explosive; extra dynamite; explosive gelatine; glyoxyline; grisoutine; gum dynamite; nitrogelatine; paleine; Punshon's explosive; Schultze's dynamite; straw dynamite; Trauzl's dynamite.

c. Consisting of nitroglycerin or an explosive gelatine incorporated with wood pulp or sawdust and a nitrate, principally sodium nitrate. Such dynamites are styled lignin-dynamites — Ætna powder; amidogene; Atlas powder; Brain's powder; carbonite; diaspon; dualin; dynamite de Krummel; dynamite de Lanky; forcite; gelatine dynamite; gelignite; giant powder; Hecla powder; meganite; miner's friend powder; grisoutite; kadmite; petralithe; rendrock; rhexite; safety nitropowder; Schultze dynamite; stonite; stowite; vigorite.

d. Other dynamites.— Americanite (nitro glycerin and methyl alcohol); Castellano's powder (nitroglycerin, fibrous material, earth and nitrobenzene); cerberite (nitroglycerin, wood oil, nitrobenzene, wood pulp, and sodium nitrate); Engle's powder (nitroglycerin, ammoniacal salts, saltpetre, pyroxyline, nitrostarch, nitromannite, nitrobenzene, and water glass); glukodine (nitroglycerin and nitrosaccharose); perunite or terrorite (nitroglycerin, nitromethyl, nitroethyl, and pyroxylin); thunder powder (nitroglycerin and nitroglucose).

C. *Organic nitrate mixtures other than dynamites.*— Casteau's explosive (nitrodextrine and ammonium nitrate); Cooppal's powders (resinous bodies, barium nitrate, and nitrocellulose); diflamyr (metallic nitrates and nitrocellulose); flamminore (collodion cotton, ammonium sulphate, and ammonium nitrate); grenée powder (paraffin; agar-agar, nitrocellulose, potassium nitrate, and barium nitrate); explosive P, (nitrocellulose and ammonium nitrate); potentite and tonite (guncotton and barium nitrate).

5. *Nitrosubstitution compounds and mixtures containing them.*— Compounds: Nitrobenzenes; nitrocresols; nitrocumenes; nitronaphthalenes; nitronaphthols; nitrophenols; nitroresorcinols; nitrotoluenes; picric acid or cabazotic acid (trinitrophenol); picramic acid; styphnic acid or oxypicric acid (nitroresorcinol).

A. Mixtures containing nitrosubstitution compounds.— Abel's powder; ammonite; amvis; bellite; boritine; Borlinetto's powder; Boyd's powder; bronolithe; Brugere's powder; explosive A; explosive C; explosive N; cremonites; Du Bois-Raymond's powders; duplexite; ecrasite; emmensite; Faversham powders; Favier explosives; ferrifractor; Fontaine's powder; Gathhurst powder; gelbite; Geserick's powder; Girard's powder; hellhoffite; Hill's powder; Johnite; joveite; kinetite; lyddite; melinite; oxonite; rackarock; roburite; romite; securite; streetites; Volney powders.

(6) *Fulminates.*— Compounds: Copper acetylide; diazobenzene nitrate; fulminating gold (auramine); fulminating silver (argentamine); mercuric fulminate; mercuric triazotate; nitrogen chloride (chloramide); nitrogen iodide (iodamide); silver fulminate; and triazoic acid, also called hydrazoic acid and azoimide.

In addition to these classes there are four groups of explosives which have received such widespread notice as to merit especial mention here, though the members of each may all be and many of them are included in the classes given above. These groups are Sprengel explosives, safety or flameless explosives, permitted explosives, and smokeless powders.

Sprengel Explosives.— These explosives were invented by Dr. Hermann Sprengel, 1873, and he advocated their use because of their safety, as they are non-explosive during manufacture, storage, and transportation, but are very powerful explosives when prepared and detonated. His plan was to employ mixtures of combustible and oxidizing substances, which should be kept separate until needed for use, the bodies to be employed in the compounding of the explosives being either all liquid or part liquid and part solid, for by taking advantage of the liquid state speedy and intimate mixing could be realized and the explosives could be compounded on the spot and at the time they were wanted for use. Among the oxidizing agents proposed were the nitrates and chlorates, which are solids, and nitric acid and nitrogen tetroxide, which are liquids. Among the combustible substances were the nitrosubstitution bodies, carbon disulphide, and petroleum. A conspicuous example of a Sprengel explosive is rackarock, which was used in blowing up Flood Rock in Hell Gate, N. Y., and which may be made by pouring mononitrobenzene upon potassium chlorate crystals. Other examples are some forms of emmensite; explosive A; hellhoffite; oxonite; panclastite; and Parone's explosive.

Safety or Flameless Explosives.— These explosives are for use in fiery mines, particularly coal mines, where there is a chance of an accident arising through the ignition of the fire damp from the flame or incandescent particles given off by the explosive as the blast is fired. Among the earlier devices employed to prevent this was the mixing in the dope of the dynamite or with the powder of a quantity of washing soda, alum, Epsom salts or other salt containing a large amount of water of crystallization that would be set free when the mixture was fired. In 1883 Mallard and Le Chatelier discovered that when explosives were detonated unconfined in air containing 10 per cent of methane (marsh-gas), the fire damp could not be ignited if the temperature of detonation was below 2200° C., owing to the cooling of the gases due to their rapid expansion and to the retardation of the inflammation of the fire-damp. An investigation by the French Fire Damp Commission showed that, among others, certain salts of ammonia and especially ammonium nitrate, were capable of reducing the temperature of the gases produced by detonation very materially, the temperature of the gases from explosive gelatine being reduced from 3090° C., when detonated alone, to 1493° C., if detonated when mixed with 88 per cent of ammonium nitrate. In August 1890 the French government prohibited the use of black powder in fiery or dusty mines and permitted the use in them of explosives whose gases are not combustible and the detonation temperature of which does not exceed 1900° C., where blasting is to be done in the rock, nor 1500° C., where the work is to be done in the coal seam. Among the explosives designed to meet such conditions and styled abroad safety or flameless explosives are: Ammonite; amvis, aphosite; bellite; benedite; britainite; cambrite; Casteau's explosives; dahmenite; Favier's explosive; fractorite; Geserick's powder; grisoutine; grisoutite; nitroferrite; progressite; roburite; securite; westphalite; wetterdynamite.

Permitted Explosives are those which have passed the prescribed tests of the governmental authorities in Great Britain and whose sale and use is authorized under carefully prescribed conditions.

Smokeless Powders are high powdered propellents used as substitutes for gunpowder in firearms and cannon. They are formed of the highest grade of cellulose nitrate only, like indurite, or of the medium grade only, like pyrocellulose powder, or they may be mixtures of different grades together with metallic nitrates like the B. N. powders. Another class are mixtures of cellulose nitrates with nitroglycerin and a restrainer, like vaseline; ballistite, cordite, and filite being examples of this kind. In robin-hood, gold dust, and gelbite, we have examples of such powders made from nitrosubstitution compounds and oxidizing agents. Other smokeless powders are amberite; Brackett's powder; cannonite; Curtis and Andre's powder; Du Pont powder; E. C. powder; fulgor; granulite; hornite; J. B. powder; kolfite; poudre J; poudre S; pyrocollodion; rifleite; Schultze powder, and Walsrode powder.

Methods of Firing Explosives.— Explosives may be made to explode by heating them to their explosion temperatures. This may be accomplished by a flame, a spark, an incandescent body, friction, percussion, concussion, pressure, or chemical action, provided the resulting temperature is sufficiently high. Gunpowder was originally ignited in muskets, guns, and boreholes by the application of a torch, a glowing tinder, or a heated iron rod. Later muskets were fired by the sparks from a flint striking steel. Joseph Egg, an English gunmaker, 1815, invented percussion caps, and to-day all fixed ammunition is fired by percussion primers, while the charges in very large guns are fired by friction primers or by electric primers. In firing blasts a train of powder was laid from the mine to a safe distance by which to convey the inflammation. Later quills, straws, or paper or wooden tubes were used to hold the train and permit of the charge being tamped so as to secure the advantage which comes from confining an explosive. Bickford of Tuckingwall, England, 1831, invented the «running» or «tape» or «safety» fuse, in which a core of gunpowder is enclosed in a tube of jute yarn impregnated with a waterproof composition, and this is to-day largely used in firing blasts. Dr. Watson of England, 1745, succeeded in igniting gunpowder by means of electric sparks, and in 1749 a battery of 11 guns was fired by means of a frictional electric machine at Annapolis, Maryland. Dr. Robert Hare of Philadelphia, 1832, invented the method of firing gunpowder charges by means of the electric current, using low tension fuses, and he had for some time prior to this employed the voltaic battery, in eudiometrical experiments, for igniting explosive mixtures of gases. Sir Charles Wheatstone, 1856, introduced the magneto-exploder in blasting, and Moses G. Farmer, of Newport, R. I., 1871, invented the dynamo-electric machine with which to generate the current and applied it to firing electric ignitors or detonators, and to-day great guns, military and naval mines, and torpedoes and many blasts, especially those in which several charges are to be fired simultaneously or where the blast is under water, are fired by this means.

It has long been known that when a notable quantity of a mixture of two volumes of hydrogen with one volume of oxygen is ignited at any point, the inflammation extends almost instantaneously throughout the mass and a most violent explosion ensues. This phenomenon is called detonation, and this mixture has long been known under the name of detonating gas. Certain chemical compounds such as nitrogen chloride, nitrogen iodide, and mercuric fulminate undergo an almost instantaneous decomposition, giving rise to violent explosive effects, if heated, struck or rubbed, and they are known as detonating explosives. At first guncotton, nitroglycerin, and dynamite were fired by ignition as gunpowder had been, but Nobel, 1866, discovered that if a quantity of mercuric fulminate was detonated in contact with nitroglycerin or dynamite they then underwent a detonating explosion also. E. O. Brown of the chemical department at Woolwich, England, 1868, discovered that not only could dry compressed military guncotton be detonated in this way, but that if the dry charge, called a primer, was in contact with wet guncotton, the latter was detonated also, even though it was saturated with or submerged under and in contact with water. There are then two kinds of explosion, namely, explosion by simple combustion and explosion by detonation. Explosives of the gunpowder class undergo only the first kind of explosion. Explosives of the nitric ester or nitrosubstitution classes undergo both kinds of explosions. Explosives of the fulminate class practically undergo only the second kind of explosion. A marked difference between the two kinds of explosion is found in the velocity with which the explosive reaction is propagated within the mass of the explosive. Thus in detonating gas, which can undergo both kinds of explosion, Bunsen found, when using very narrow tubes where only combustion could take place, that the velocity of the reaction was 34 metres per second, while Berthelot, using long and wide tubes in which detonation could take place, found that the velocity of the reaction was 2,810 metres per second. Experiments made by laying trains of the materials and firing them showed that while the velocity of combustion of gunpowder in the open air is but from 1.5 to 3.4 metres per second, the velocity of detonation of dynamite and of guncotton is about 6,000 metres per second. Provided each explosive gave the same volume of gases, having the same temperature and that the conditions were in all other respects alike, it is evident that the explosion in which the reaction velocity was the greater would be the more violent one. But they are not alike since guncotton, nitroglycerin, and mercuric fulminate, besides being endothermous compounds, are completely resolved into gases, while gunpowder, besides being a mixture, yields but about 44 per cent of gaseous products. The pressure developed by gunpowder when fired in a space completely filled by it is, from Noble and Abel's experiments, 6,150 atmospheres. The theoretical pressures developed by guncotton, nitroglycerin, and mercuric fulminate when detonated in contact with bodies, are respectively 24,000 atmospheres, 25,000 atmospheres, and 28,000 atmospheres. Investigation has shown that no other explosive known will give in contact an instantaneous pressure at all comparable with that of mercuric fulminate.

Owing to these differences in behavior explosives have been distinguished as high explosives and low explosives. Gunpowder and explosives of the nitrate class, together with smokeless powder are low explosives. They act with comparative slowness and are used where it is desired to lift or push a load without cracking it or in propelling projectiles. Nitroglycerin and explosives of the class of nitric esters or nitrosubstitution bodies are high explosives. They are shattering and crushing in their effect. Detonators containing mercuric fulminate are used to fire high explosives, the detonators being themselves fired by means of a Bickford fuse or by an electric current. The high explosives are usually put up for use in paper cylinders, and, when loaded for shipment, these are called cartridges or «sticks.» Usually several sticks are required for one borehole. In this case the detonator is inserted in one of these sticks, usually the last one inserted in the hole, and this stick is then called the priming cartridge or «primer.»

Direction in Which Explosives Explode.— There is a very common but erroneous belief that gunpowder explodes upward and that high explosives explode downward. It arises from the fact that if a quantity of dynamite be laid unconfined upon the surface of the rock on detonating it the rock will often be fractured, whereas if gunpowder is thus placed and fired, it produces no effect whatever upon the rock. The facts are that each explosive tends to act in all directions about the centre of explosion. As exposed in air they are subjected to the weight of the air above them, and are to that extent under confinement. When the high explosive is detonated the gases are set free so fast that the air acts as a tamping agent; when the gunpowder explodes the gases are generated so slowly that they have time to move the air. Besides the «pressure in contact» exerted by the high explosives is enormously greater than that of the low explosives. That high explosives exert pressure in all directions may be easily demonstrated by fastening blocks of guncotton of equal size and weight on opposite sides of a plate of iron, but at some distance apart, by means of light cords or wires, suspending the plate in any position and detonating both charges simultaneously when holes will be blown through the plate away from each of the charges. Although high explosives usually produce a shattering effect when fired unconfined upon a body the effect is markedly increased by increasing the confinement. Thus in the method of breaking boulders and large masses of stone called «plastering,» after the charge is laid upon the stone and fused, one or two shovelfuls of earth are placed over it before firing. In «blockholing,» when it is desired to break the rock into fragments of definite size, a small hole is bored in the rock and the explosive inserted in this cavity whereby the gases obtain a greater leverage.

Explosions by Influence.—In detonating explosive substances it has been found that the influence of the detonation is exerted to a distance all about the mass depending on the kind and the amount of the explosive used and its environment and that a second charge of explosive within the sphere of influence may be detonated by the detonation of the first charge without being in contact with it. Thus in accidental explosions in explosive works the initial explosion occurring in one building may detonate the explosives in other buildings unless care is taken in the construction of the works to separate the buildings by a safe distance from one another. Care, too, must be taken in forming fixed ammunition that the primers are not heavily charged with fulminate, and that the cartridges are so packed that the accidental explosion of one cannot explode the others by influence. Application of this principle is made in military engineering in the operation of countermining, the enemy's submarine mines being blown up by firing a heavy torpedo charged with guncotton in the vicinity of them. To-day large quantities of explosives are frequently used in big blasts. According to Eissler, it is an almost daily occurrence in California for 20,000, 30,000, and even 50,000 pounds of explosives to be used in a single charge. The system of large blasts has even become common in hard rock excavations, such as quarries and railroad cuttings, and in these large blasts it is common practice to dispose the larger part of the mass of explosive so that it may be exploded by influence and not by contact or by propagation of flame or fire.

The largest single blast ever fired was that used in the blowing up of Flood Rock at Hell Gate in the East River, N. Y., 10 Oct. 1885. There was used in the blast 240,399 pounds of rackarock and 42,331 pounds of dynamite, or 283,000 pounds of explosive. There were 13,000 separate charges of rackarock embedded in drill holes with a dynamite cartridge on top of each, and there were 591 primary charges of dynamite placed on timbers 25 feet apart within the mine. When all the charges had been placed in the excavation and the primary charges connected with the firing batteries, the mine was filled with water, the primary charges were exploded by the electric current and these exploded the 13,000 other charges by influence through the intervening water. Munroe founded on this principle a method of testing the relative sensitiveness of explosive substances.

Uses of Explosives.— The uses of explosives as propellents in war and in the chase; as rupturing agents in mining, quarrying, and engineering operations; and as an essential component of fireworks is well known. It is not so generally known that they are employed for saving life and property in signal lights, rockets, and guns; in projecting lines from the shore to stranded ships, and, in case of fire, to the upper stories of high buildings; in casting oil upon the water to quell a raging sea; and in railroad torpedoes to prevent collisions. Gunpowder guns are also used in bridge building to project a line across a chasm which is to be bridged, and they are used in the whale fishery to project the harpoons, while the latter may carry an explosive charge with which to stun or destroy the whale. Detonating explosives have been improperly used in taking fish; in burglarious operations against safes and vaults and in anarchistic outrages. Dynamite has been used to knock the blocking from the ways when launching ships. Fired on an iron plate placed on the top of a pile and covered with a tamping of earth or clay, it has successfully replaced the pile driver. It has been found efficient in excavating holes in which to plant telegraph and telephone poles and fence posts; in driving water out of quicksands in which foundations are to be laid or shafts to be driven; in slaughtering cattle; in breaking down ice dams to prevent inundations; in blowing up buildings to prevent the spread of conflagrations; in razing unsafe walls of burned buildings; in destroying wrecks which endanger navigation, and in freeing vessels which are hard aground on shoals. The farmer uses them in breaking boulders, grubbing stumps, and felling trees; in shaking the soil to fit it for deep-soil cultivation, and, in wine growing districts, to free the soils from the phylloxera: while their aid has been sought in breaking droughts and diverting hailstorms from their courses. The iron founder uses them in breaking large castings. The iron smelter employs them to clear out obstructions in blast furnaces while the latter are still in operation. Munroe proposed using detonating explosives as a means of testing the integrity of large masses of metal and their resistance to shock.

Explosives Industry in the United States.— From the reports of the Twelfth Census of the United States it appears that in the year ending 30 June 1900 there was produced 25,638,804 pounds of gunpowder; 977,442,237 pounds of blasting powder; 35,482,947 pounds of nitroglycerin; 3,662,633 pounds of cellulose nitrates; 85,846,456 pounds of dynamite, and 3,053,126 pounds of smokeless powder. The comparative condition of the industry from 1840 to 1900 is shown in the following table:

TOTAL PRODUCTION AND VALUE OF EXPLOSIVES IN THE UNITED STATES BY DECADES, 1840–1900.

	No. of establishments	Capital	Average No. of wage earners	Products	
				Pounds	Value
1840....	137	$ 875,875	496	8,977,348	....
1850....	54	1,179,223	579	....	$ 1,590,332
1860....	58	2,305,700	747	....	3,223,090
1870....	36	4,099,900	973	....	4,237,539
1880 ...	54	6,585,185	1,340	....	5,802,029
1890....	69	13,539,478	2,353	98,645,912	10,993,131
1900....	97	19,465,846	4,502	215,590,719	*16,950,976

* This value is for the explosive substances only. When materials of all kinds produced in these establishments are included, the value is $17,125,418.

The establishments reported for 1900 were most numerous in the sections where mining or engineering operations were carried on most extensively. Though Pennsylvania had 36 factories and the largest output was in the Middle Atlantic States, yet California alone manufactured over one fourth of the entire annual output, and was the largest producer in the United States. See DYNAMITE; FIRE-DAMP; GUNPOWDER; NITROGLYCERIN; MAXIMITE; STABILITE.

Bibliography.— In addition to the books heretofore cited, the following are of value: Abbott, ‹Report Upon Experiments and Investigations to Develop a System of Submarine Mines› (1881); Bernadou, ‹Smokeless Powder› (1901); Berthelot, ‹Les feu grègois et les origines de la poudre à canon› (1891); Chalon, ‹Les Explosifs Modernes› (1886); Cundill, ‹A Dictionary of Explosives› (1889); Daniel, ‹Dictionnaire des Matières Explosives› (1902); DeKalb, ‹Manual of Explosives› (1900); Désortiaux, ‹Dictionnaire des Explosifs› (1892); Drinker, ‹Tunneling, Explosive Compounds, and Rock Drills› (1882); Eissler, ‹A Handbook on Modern Explosives› (1890); Eissler, ‹The Modern High Explosives› (1893); Guttmann, ‹The Manufacture of Explosives› (1895); Hill, ‹Notes on Certain Explosive Agents› (1875); Maquet, ‹Explosifs de Sureté› (1893); Mowbray, ‹Tri-nitro-glycerin as Applied in the Hoosac Tunnel› (1874); Munroe, ‹Lectures on Chemistry and Explosives› (1888); Munroe, ‹Index to the Literature of Explosives› (1893); Munroe and Chatard, ‹Chemicals and Allied Products,› Bulletin 210 United States Census (1902); Nobel, ‹Les Explosifs Modernes› (1876); Walke, ‹Lectures on Explosives› (1897); Wisser, ‹Compressed Guncotton for Military Use› (1886).

CHARLES E. MUNROE,
The George Washington University, Washington, D. C.

Exports and Imports, American. The interchange of commodities among nations, a process now seen in its highest and most elaborate forms of development in the commercial relations between manufacturers, merchants, and financiers of the United States and those of other countries, owes its origin to the brave, enterprising adventurers of Southern Europe, France, Holland, and England, who, during the 14th, 15th, and 16th centuries, scoured the seas in quest of territory for occupation and the exploitation of trifling commercial ventures.

The motives of these men were not primarily patriotic as a rule, but they were, in the hands of Providence, to be the foundation-layers of a gigantic, world-wide commercial, political, and social structure such as now exists and is forever expanding.

The discovery and occupation of the Canary Islands, Madeira and the Azores; the doubling of the Cape of Good Hope by Vasco de Gama; the finding of Zanzibar and penetration eastward to the mainland of India; the crossing, thrice, of the Atlantic by Columbus; his landings at Jamaica and Porto Rico; the finding, by Cabot, of Newfoundland, Labrador, Nova Scotia, Virginia, and the present Canadian territory — these events, and such as these, gave an impetus to adventurous navigation that has continued without intermission and still dominates among expert sailors and explorers. Arctic and Antarctic expeditions are among the most modern illustrations of the Caucasian tendency to seek a further knowledge of the world's resources and hidden treasures.

The establishments, by Portuguese traders, of the first European factory in India, soon after the results of de Gama's expedition became known; the founding of the English East India Company and the explorations of Spain in Mexico and Peru were among the most important events leading, directly or indirectly, to a magnitude of commercial operations such as is now illustrated in the grand aggregates of United States exports and imports.

Portugal, figuring but little in 20th century commerce, at that time led the way in discoveries of subsequently profitable markets on the coast of Africa, in India, and in the Indian archipelago. Spain, now so trifling in stature among nations, in those days pervaded what might be termed the atmosphere of adventure and by her mining work in Central and South America greatly increased the world's available stock of precious metals. French activity in the East and West Indies, in Canada and in the Mississippi region helped to swell the tide of commercial progress. Dutch aggressiveness in New Amsterdam and English colonial development also contributed substantially to the general advance.

Conspicuous among events connected with the beginnings of New World commerce, which consisted principally of dealings in foodstuffs, metals, dyes, tissues, and chemical substances, was the importation of negroes, begun by Spain, in the early part of the 16th century. The employment of this class of forced-servitude workers into the West Indies was started by England in 1652. Then followed their introduction by landowners and others in New England and the Southern States.

The declaration of peace in 1783 found the United States occupying, as their only territory, the strip bordering the Atlantic from Maine to Florida. This territory was bounded on the west by the Mississippi River. Seven years later, with a total settled area of 240,000 miles and an aggregate population estimated at four millions, the principal commercial products were as follows:

Tobacco, grown in Virginia and Maryland and sent abroad to all countries.

Rice and indigo, grown in the Carolinas and highly esteemed in European markets.

Fish and lumber, products of New England and sold extensively in the West Indies, then European colonial possessions.

Furs. New York was the centre of the fur trade.

Agriculture. Agricultural industries were developing in the Northwest.

Commercial extension in the United States, from 1790, was brought about by annexation of territory west of the Mississippi and to the southward, including Florida and Texas. From the start, agriculture has furnished, and still furnishes, the bulk of United States exports, cotton, hog products, wheat flour, wood, animals, beef products, and wheat figuring as leading items, with an aggregate value of $786,000,000. Manufacturing, as a recognized feature of United States commerce and, consequently, an important division in the consideration of increasing exports and decreasing imports, began in 1816. The inventive genius of Americans, ever since that time, has aided and encouraged capital and enterprise in bringing American-manufactured products to the prominence now so universally accorded them. The Federal census returns of 1900, recently issued, report, in their completed form, 641,000 manufacturing establishments in the United States, employing $10,000,000,000 of capital owned by 709,000 proprietors. The number of wage-earners is given as 5,400,000, receiving $2,400,000,000 in wages. The total cost of materials is reported as nearly $7,400,000,000 and the value of products as over $13,000,000,000.

The American export trade, in spite of many fluctuations in financial, commercial, and political conditions, has shown a steady growth, unmarked by any startling decreases such as might reasonably have been expected as a result of panics, wars, labor troubles, and other disturbances, local, State, National, and international. During the past 27 years the total of merchandise exports from the United States has remained above $600,000,000. During 1879, 1882, 1884, 1885, 1887, and 1889 the total was between $700,000,000 and $800,000,000; during 1880, 1883, 1890, 1891, 1893–1896, it was between $800,000,000 and $900,000,000; during nine other years the total of exports has exceeded $1,000,000,000.

Exports from United States — Merchandise and Specie.— The grand total of merchandise and specie exports, domestic and foreign, from the United States during the fiscal year 1904 amounted in value to $1,600,000,000. The 10 largest aggregates, in their order of value, were: Cotton (unmanufactured), $371,000,000; iron and steel (manufactures of), $112,000,000; hog products, $105,000,000; mineral oils (refined or manufactured), $72,000,000; wheat flour, $69,000,000; wood (and manufactures of), $65,000,000; copper (manufactures of), $57,000,000; animals, $48,000,000; beef products, $40,000,000, and wheat, $36,000,000. The aggregate for the 10 industries, 1904, as shown above, is $975,000,000.

For the fiscal year ending June 30, 1905, the same ten export aggregates as shown above were: Cotton (unmanufactured), $381,000,000; iron and steel (manufactures of), $135,000,000; hog products, $106,000,000; mineral oils (refined or manufactured), $73,000,000; wheat flour, $40,000,000; wood (and manufactures of), $58,000,000; copper (manufactures of), $86,000,000; animals, $47,000,000; beef products, $35,000,000, and wheat, $4,000,000.

Imports to United States — Merchandise and Specie.— The grand total of merchandise and specie imports into the United States during the fiscal year 1904 amounted in value to $1,125,000,000. The 10 largest aggregates, in their order, were: Sugar, $72,000,000; coffee, $70,000,000; chemicals, $65,000,000; hides and skins, other than fur, $52,000,000; manufactures of cotton, $50,000,000; silk (unmanufactured), $46,000,000; india rubber and gutta percha (crude), $41,000,000; fibres, vegetable (manufactures of), $40,000,000; fibres, vegetable (unmanufactured), $38,000,000, and silk (manufactures of), $32,000,000. The aggregate for the 10 industries, 1904, as shown above, is $506,000,000. Considering only the 10 classes of products outgoing and incoming, the excess of outgoing over incoming products, 1904, was, in round numbers, $469,000,000. A remarkable feature of the aggregate showing for 1904 under the two general headings shown above, including all industries and products, is that almost exactly the same proportion of excess in exports over imports as revealed in 10 products appears. (See table following.)

For the fiscal year ending June 30, 1905, the same ten import aggregates as shown above were: Sugar, $98,000,000; coffee, $85,000,000; chemicals, $65,000,000; hides and skins, other than fur, $65,000,000; manufactures of cotton, $49,000,000; silk (unmanufactured), $61,000,000; india rubber and gutta percha (crude), $51,000,000; fibres, vegetable (manufactures of), $40,000,000; fibres, vegetable (unmanufactured), $38,000,000; silks (manufactures of), $33,000,000.

Exports and Imports, 1791–1904, with Excesses of Each.— The following table presents a compact view of United States exports and imports covering a period of 113 years. It will be noted that there has been a substantial excess of exports over imports each year since 1893.

TOTAL VALUES OF ALL EXPORTS AND IMPORTS, EXCEPT GOLD AND SILVER,† FROM 1791 TO 1905.

Year	Exports	Imports	Excess
1791........	$19,012,041	$29,200,000	Imp. $10,187,959
1800........	70,971,780	91,252,768	Imp. 20,280,988
1810........	66,757,970	85 400,000	Imp. 18,642,030
1820........	69,691,669	74,450,000	Imp. 4,758,331
1830........	71,670,735	62,7[illegible]9,956	Exp. 8,940,779
1840........	123,668,932	98,258,706	Exp. 25,410,220
1850........	144,375,726	173,509,526	Imp. 29,133,800
1860........	333,576,057	353,616,119	Imp. 20,040,062
1870........	392,771,768	435,958,408	Imp. 43,186,640
1880........	835,638,658	667,954,746	Exp. 167,683,912
1885........	742,189,755	577,527,329	Exp. 164,662,426
1890........	85[illegible],828,684	789,310,409	Exp. 68,518,275
1892*.......	1,030,278,148	827,402,462	Exp. 202,876,686
1893**......	847,665,194	866,400,922	Imp. 18,737,728
1895........	807,538,165	731,969,965	Exp. 75,568,200
1897*.......	1,050,993,556	764,730,412	Exp. 286,263,144
1900........	1,394,483,082	849,941,184	Exp. 544,541,898
1901........	1,487,764,991	823,172,165	Exp. 664,592,826
1902........	1,381,719,401	903,320,948	Exp. 478,398,453
1903........	1,419,991,290	1,025,619,127	Exp. 394,372,163
1904........	1,460,868,185	991,090,978	Exp. 469,777,207
1905........	1,518,561,666	1,117,513,071	Exp. 401,048,595

*Given because exports here passed the billion mark.
**Given because last year of excess of imports.
†Gold specie exported, 1904, $81,000,000; silver specie, $50,000,000.

Exports, Merchandise, 1904; *Value, by Principal Countries.*— The ten greatest values in merchandise sent from the United States during the fiscal year 1904 went to the following countries: Great Britain and Ireland, $538,000,000; Germany, $213,000,000; British North America, $134,000,000; France, $85,000,0000; Netherland, $72,000,000; Mexico, $46,000,000; West Indies, $44,000,000; Belgium, $41,000,000; Italy, $36,000,000, and British Australasia, $27,000,000. The aggregate value of merchandise sent to the ten countries given above is $1,250,000,000.

1905. Great Britain and Ireland, $523,000,000; Germany, $194,000,000; British North America, $143,000,000; France, $76,000,000; Netherlands, $73,000,000; Mexico, $46,000,000; West Indies, $55,000,000; Belgium, $38,000,000, and British Australasia, $26,000,000. The aggregate value of merchandise sent to the ten countries given above during the year ending June 30, 1905, was $1,174,000,000.

EXPORTS FROM THE UNITED STATES TO OTHER COUNTRIES.

Divisions	Value, 1800	Value, 1850	Value, 1905
Europe..........	$41,000,000	$114,000,000	$1,021,000,000
North America..	27,000,000	25,000,000	261,000,000

Africa..........	1,000,000	977,000	19,000,000

*1810.

Imports, Merchandise, 1904; *Value by Principal Countries.*— The ten greatest values in merchandise received in the United States from other countries, in their order, during the fiscal year 1904 were: From Great Britain and Ireland, $164,000,000; Germany, $109,000,000; France, $81,000,000; Cuba, $77,000,000; Brazil, $76,000,000; East Indies, $58,000,000; British North America, $50,000,000; Japan, $47,000,000; Mexico, $44,000,000 and Italy, $34,000,000. The aggregate value of merchandise sent to the United States from the ten countries given above is $740,000,000.

1905. Great Britain and Ireland, $176,000,000; Germany, $118,000,000; France, $89,000,000; Cuba, $86,000,000; Brazil, $100,000,000; East Indies, $72,000,000; British North America, $63,000,000; Japan, $52,000,000; Mexico, $46,000,000, and Italy, $39,000,000. The aggregate value of merchandise sent to the United States from the ten countries given above during the year ending June 30, 1905, was $841,000,000.

THE WORLD'S EXPORTS TO THE UNITED STATES.

Grand Divisions	Value, 1800	Value, 1850	Value, 1904
Europe	$47,000,000	$125,000,000	$499,000,000
North America..	32,000,000	24,000,000	199,000,000
South America...	*6,000,000	17,000,000	120,000,000
Asia	12,000,000	10,000,000	144,000,000
Oceanica	143,000	1,500,000	20,000,000
Africa	551,000	682,000	9,500,000

*1830.

Exports from United States, from Principal Ports.— In their order of value, the principal ports of the United States shipped to other countries, during the fiscal year 1904, as follows: New York, $507,000,000; New Orleans, $149,000,000; Galveston, $145,000,000; Boston and Charlestown, $90,000,000; Baltimore, $83,000,000; Philadelphia, $71,000,000; Savannah, $54,000,000; San Francisco, $33,000,000; Puget Sound, $23,000,000, and Wilmington, N. C., $19,000,000. The increase for the above ports over 1903 were: New York, $1,000,000; Galveston, $40,000,000; Boston and Charlestown, $1,750,000; Baltimore, $1,000,000; Puget Sound, $250,000; Wilmington, N. C., $4,000,000.

Imports Received at Principal Ports of United States.— In their order of value of imports the record shows the following amounts: New York, $600,000,000; Boston and Charlestown, $81,000,000; Philadelphia, $54,000,000; San Francisco, $38,000,000; New Orleans, $34,000,000; Baltimore, $20,000,000; Puget Sound, $11,000,000; Detroit, $4,000,000; Mobile, $4,000,000; Newport News, $2,000,000; Galveston, $1,800,000; Charleston, $1,700,000, and Portland, Me., $1,400,000. The increase in imports received for the above ports over 1903 were: San Francisco, $1,000,000; New Orleans, $5,000,000; Detroit, $165,000; Mobile, $100,000; Galveston, $300,000. The decreases were: New York, $18,400,000; Boston and Charlestown, $6,000,000; Philadelphia, $6,000,000; Baltimore $7,500,000; Puget Sound, $1,000,000; Newport News, $2,000,000; Charleston, $400,000, and Portland, Me., $1,000,000.

Exports from United States by Classes.— The aggregates under several great headings in 1860 and 1904, respectively, are given below. They make a remarkable showing of national development.

Agricultural exports.....	1860, valued at.....	$257,000,000
	1904, " "	854,000,000
Mining exports..........	1860, " "	1,000,000
	1904, " "	46,000,000
Forest exports...........	1860, " "	10,000,000
	1904, " "	69,000,000

Fisheries exports........	1860, valued at	$4,000,000
	1904, " "	9,000,000
Total value of domestic manufactures exported	1860, " "	40,000 000
	1904, " "	452,000,000

Exports and Imports, Cuba, Porto Rico, Hawaii, and the Philippines.— The following tabular exhibit is interesting as an example of progress through close commercial and political contact with the United States:

Years	Cuba	Porto Rico	Hawaii	Philippines
1888				
Exports from U. S.	$10,000,000	$2,000,000	$2,000,000	$166,000
Imports to U. S...	49,000,000	4,000,000	11,000,000	10,000,000
1899				
Exports from U. S.	$19,000,000	$3,000,000	$9,000,000	$400,000
Imports to U. S...	25,000,000	3,000,000	18,000,000	4,000,000
1905				
Exports from U. S.	$38,000,000	$14,000,000	$12,000,000	$6,000,000
Imports to U. S...	86,000,000	16,000,000	36,000,000	13,000,000

Exports from United States, Increase during Decade.— The increase in total value of exports from the United States to Europe 1893–1904, as shown by comparison of totals for 1893 and 1904, was $396,000,000; to North America, $115,000,000; to South America, $18,000,000; to Asia and Oceanica, $66,000,000; Africa and other countries, $18,000,000. The total increase in volume of outward trade of the United States to the geographical divisions shown above is $613,000,000.

Exports and Imports, 1904, *Compared by Same Principal Classes of Products.*— The value of provisions exported from the United States, 1904, was $175,000,000; imported to the United States, $4,000,000; iron and steel (manufactures of), exported, $112,000,000; imported, $27,000,000; oils, exported, $109,000,000; imported, $11,000,000; animals, exported, $48,000,000; imported, $3,000,000; leather (and manufactures of), exported, $34,000,000; imported, $11,000,000; cotton (no manufactures of), exported, $22,000,000; imported, $50,000,000; coal (bituminous), exported, $18,000,000; imported, $5,000,000.

Exports, American Vessels.— The value of exports carried from the United States in American vessels 75 years ago (1830) aggregated $64,000,000. Twenty years later the records show $100,000,000. The official reports for 1904 give a total of $97,000,000.

Exports, Foreign Vessels.—Foreign merchantmen, in 1830, took from United States ports commodities valued at $10,000,000. The amount reached, 1850, exceeded $52,000,000. The aggregate of exportations in foreign bottoms, 1904, showed values totaling $1,211,000,000.

Imports, American Vessels.—American vessels, in 1830, brought to the United States goods worth $66,000,000. This, after two decades, increased to $140,000,000. The latest official reports (1904), indicate $132,000,000 as the value, in that year, of imports arriving in American vessels.

Imports, Foreign Vessels.— The aggregate value of such imports, 1830, was over $4,000,000. In 1850, a grand total of more than $38,000,000 had been reached. The figures for 1904 under this heading show $791,000,000 as the amount represented for that year in imports brought in foreign ships.

Summary of Statistics.— The statements of fact, taken from official reports, following the introductory part of this article, show:

Exports from United States, merchandise and specie.

Imports to United States, merchandise and specie.

Exports and imports from 1791, with excesses of each.

Exports, merchandise, value of, by principal countries.

Imports, merchandise, value of, by principal countries.

Exports from United States, from principal ports.

Imports received at principal ports.

Exports from United States by classes.

Exports and imports, *Cuba,* Porto Rico, Hawaii, and the Philippines.

Exports from United States, increase during decade.

Exports and imports, compared by principal classes of products.

Exports, past and present, in American and foreign vessels.

Imports, past and present, in American and foreign vessels.

Comparison of United States Exports (1902–3) *with Those of Principal Nations.*— The ten countries showing the greatest value of exports (1904–5) from their own territory are: United States, $1,492,000,000; United Kingdom, $1,463,000,000; Germany, $1,243,000,000; France, $864,000,000; Netherlands, $797,000,000; Russia, $516,000,000; British India, $500,000,000; Austria-Hungary, $424,000,000; Belgium, $421,000,000; Italy, $312,000,000.

Comparison of United States Imports (1904–5) *with Those of Principal Nations.*— United Kingdom, $2,682,000,000; Germany, $1,515,000,000; United States, $991,000,000; Netherlands, $1,118,000,000; France, $876,000,000; Belgium, $537,000,000; Austria-Hungary, $416,000,000; Italy, $359,000,000; Russia (1903), $351,000,000; British India, $314,000,000.

Conclusion.— The exports of any country furnish a reliable indication of its productive capacity. The three countries having the greatest productive capacity are, in their order, the United States, the United Kingdom (Great Britain and Ireland) and Germany, with France and the Netherland holding creditable fourth and fifth places.

Imports show, approximately, the ability and necessity of a nation to buy. In the figures it will be noted that Great Britain and Ireland are the largest buyers, Germany being second, and the United States third.

THOMAS C. COPELAND,
Expert Statistician.

Exports and Imports of the Latin-American Republics. *Argentina.*—The total value of exports from the Argentine Republic to all other countries during the year 1902 was $179,486,727 gold; an increase of $11,760,625, as compared with the exports in 1901; and the imports aggregated only $103,039,256 gold; a decrease of $10,920,493, as compared with those of 1901. Imports during 1902 from the United States into the Argentine Republic were: Agricultural implements, valued at $2,381,735; carriages, $412,033; cycles, $10,710; cotton cloths, $77,821; wearing apparel, $214,853; electric and scientific apparatus, $110,915; builders' hardware, $232,464; sewing-machines, $129,600; steam-engines, $8,380; typewriting-machines, $24,940; leather, $56,901; rosin, tar, etc., $136,958; turpentine, $124,161; oils, $1,132,402; lard, $5,040; tobacco, $17,213; wood, $54,098; lumber, $858,888; furniture, $98,220. Imports into the Argentine Republic from Great Britain during 1902 were: Cotton manufactures, valued at $5,776,336.22; jute manufactures, $229,104.28; linen piece goods, $269,452.23; woolen tissues, $601,887.91; worsted tissues, $798,908.89; carpets, $158,440.58; cutlery, $74,126.21; hardware, $99,830.13; iron (bar, bolt, etc.), $131,548.44; railroad iron, $1,956,566.33; wire (of iron or steel), $298,516.23; galvanized sheets, $1,354,663.55; tin plates and sheets, $3,669.54; wrought and cast iron, $1,044,020.86; cement, $147,483.08; earthen- and china-ware, $163,391.48. The distribution of exports and imports is shown in the following table:

Exports from Argentina to	Value in Argentine gold	Imports into Argentina from	Value in Argentine gold
Great Britain..	$35,084,066	Great Britain..	$36,995,460
France	29,587,457	France	9,243,071
Germany	22,939,881	Germany	13,229,275
Belgium	13,760,219	Belgium	5,484,233
United States ..	10,037,576	United States..	13,303,504
Brazil	8,368,742	Brazil	4,583,645
Africa	8,285,387	Africa	
Italy	4,215,756	Italy	12,265,003
Uruguay	3,673,633	Uruguay	744,694
Netherlands ...	2,834,288	Netherlands ...	622,359
Spain	2,025,428	Spain	3,166,902
Chile	684,113	Chile	213,189

Paraguay	212,212	Paraguay	1,469,510
Other countries	10,196,675	Other countries.	1,485,124
Orders	26,509,935		

Among the articles exported to the United States in 1902 were: 224 tons of tasajo (jerked beef); 800,000 pounds of bone and bone ash; 11,020 tons of wool; 966 tons of wheat; and 14,113 tons of linseed. Exports to Great Britain during that year were: Wheat, valued at $7,129,589.47; maize, $17,287,180.23; fresh beef, $8,414,574.84; fresh mutton, $11,069,641.49; unrefined sugar, $1,483,634.44; wet hides, including shipments from Uruguay, $737,975.45; linseed, $8,681,643.18; tallow and stearin, $3,290,318.10. The total shipments of wheat from Argentina in 1902 were estimated at 700,000 tons, and the exports of butter (5,837,282 pounds) were nearly four times as large as those of 1901.

Bolivia.— The exports during 1902 were valued at $13,566,734, against $13,621,237.56 in the year 1901. Importations from all countries into Bolivia, according to consular invoices (values as given to the customs officers), amounted to $6,120,113, and to 16,953,223.75 *bolivianos*, or $6,476,131.47 United States currency, in 1901 and 1902. Exports from Bolivia consisted chiefly of silver, rubber, tin, and copper. Imported articles were bought principally from Germany, England, France, and the United States.

Brazil.— During the year 1902 Brazil exported to the United States coffee to the value of $47,004,453; india rubber, $15,209,295; sugar, $2,534,760; and cocoa, $1,302,493. Her imports from the United States in the same year were: Agricultural implements, valued at $35,702; wheat flour, $2,209,881; carriages, $54,266; cycles, etc., $6,799; cotton cloths, $603,161; wearing apparel, $81,143; electric and scientific apparatus, $323,941; builders' hardware, $188,404; sewing-machines, $74,114; steam-engines, $133,759; typewriting-machines, $12,428; leather, $155,119; rosin, tar, etc., $226,676; turpentine, $79,804; oils, $2,568,684; beef, $9,926; tallow, $26,905; bacon, $167,981; hams, $2,612; pork, $13,021; lard, $924,582; butter, $116,410; lumber, $353,175; and furniture, $16,639. Exports from Brazil to Great Britain in 1902 were: Raw cotton, valued at $5,299,665.49; coffee, $2,290,862.61; unrefined sugar, $932,001.12; wet hides, $271,850.49. Imports from Great Britain were: Coal and coke, valued at $3,687,880.53; cotton manufactures, $6,845,427.84; jute yarn, $1,787,220.33; jute manufactures, $93,148.49; linen piece goods, 246,509.66; woolen tissues, $401,940.58; worsted tissues, $490,652.50; cutlery, $147,826.77; hardware, $135,634.37; iron (bar, angle, bolt, and rod), $155,933.05; railroad iron, $597,315.24; iron- or steel-wire, $60,329.56; galvanized sheets, $205,820.55; tin plates and sheets, $372,900.77; wrought and cast iron, $890,377.75; cement, $55,513.13; earthen- and china-ware, $307,160.64; and seed oil, $295,657.70. There was a marked increase in exports to Spain and France. The aggregate of exports to all countries during the first six months of 1902 was $84,291,922.61; while the imports from all countries during the same period amounted only to 219,886 *contos*, or $52,971,457.52.

Chile.— Exports to all countries during the first half of the year 1902 had an aggregate value of $93,955,450, including gold and silver specie; or $79,745,933, excluding specie. In the corresponding period of 1901 the value of the exports was $78,682,883, including gold and silver specie, amounting to $203,119. The total value of imports in the first half of 1902 was $63,158,537; that sum being less by $2,608,044 than the imports during the corresponding period of 1901. It is stated that the diminution is due to the following causes: "In the first place, there are the rectifications made in the valuations of sugar, coffee, and tea. In the statistics for 1901 these articles figured with an excess of $3,652,000 over their real value. In the second place, the last harvest sufficed for the wants of the country, and consequently there were no heavy imports of wheat and flour, which articles in 1901 represented a value of $8,578,000. In the third place, there was the higher premium on gold, and transitory circumstances which perturbed trade and reduced personal consumption." Instead of importing wheat, as in 1901, Chile sent more than 15,000 tons of that product to Peru. Imports from the United States during the entire year 1902 were: Agricultural implements, valued at $132,242; carriages, cars, etc., $115,276; cotton cloth, $520,642; wearing apparel, $29,311; electric and scientific apparatus, $52,979; builders' hardware, $123,116; leather, $28,398; rosin, tar, etc., $15,593; turpentine, $34,105; oils, $554,080; beef, $7,493; tallow, $3,020; lard, $42,681; wood, $5,371; lumber, $199,183; and furniture, $14,844. Imports into Chile from Great Britain during 1902 were: Cotton manufactures, valued at $3,065,788.29; woolen tissues, $520,422.81; worsted tissues, $810,723.76; carpets, $121,409.10; cutlery, $65,384.62; hardware, $102,771.61; iron (angle, bar, bolt, and rod), $166,554.00; railroad iron, $181,173.74; galvanized sheets, $378,598.67; and wrought and cast iron, $171,163.62. Exports from Chile to Great Britain in 1902 were principally nitrate of soda and copper (namely, copper ore, $1,419,224.76; regulus and precipitate, $1,226,558.20; and wrought and unwrought copper, $4,452,300.10). British importations of nitrate of soda during 1902 had a total value of $5,122,606.90, most of which came from Chile. The British empire (on account of the business done with India) heads the list of importers, and Germany stands next in order.

Colombia.— According to official statistics of the United States, Colombia imported from this country in 1902: Agricultural implements, $3,553; wheat flour, $231,828; carriages, $21,675; cycles, $937; cotton cloths, $1,286,535; wearing apparel, $76,398; builders' hardware, $55,667; sewing-machines, $19,129; steam-engines, $21,400; typewriting machines, $3,227; leather, $14,297; boots and shoes, $80,514; rosin, tar, etc., $11,705; turpentine, $5,802; oils, $115,884; beef, $27,310; tallow, $3,880; bacon, $2,971; hams, $15,444; pork, $14,133; lard, $109,952; butter, $13,626; cheese, $10,960; tobacco, $70,869; wood, $12,718; lumber, $36,992; and furniture, $24,327. Imports into Colombia from Great Britain during the same year were: Cotton manufactures, $3,129,788.29; and linen piece goods, $60,595.52. The only available commercial statistics of a Colombian source are those of the port of Cartagena. The total value of imports there during 1902 is given as $1,601,159.28 United States gold. Reliable statistics of exports in 1902 cannot be obtained.

Costa Rica.— Exports of coffee (1 Oct. 1901 to 30 Sept. 1902) amounted to 236,057 sacks. Exports of bananas in 1902 were greater than in any preceding year — 4,174,199 bunches, worth, approximately, $1,878,389.55. Other exports in 1902: cocobola logs, valued at $7,187.04; fustic (*palo mora*), $43,514.28; mahogany, $2,487.60; cedar timber, $117,007.80; cacao, $24,051.20; sundry merchandise by parcels-post, $8,934.67; gold by parcels-post, $11,630.63; total gold and silver coin and bullion, $147,340.59; not enumerated, $41,184.44. Imports into Costa Rica from the United States in 1902 were valued at $2,048,809; that sum being 54 per cent of the total value of Costa Rica's imports, which was $3,794,642. Great Britain furnished 24 per cent of the imports, Germany 12½ per cent, and France a little over 5 per cent. The chief imports from the United States were foodstuffs, machinery, and tools, cotton prints, dynamite, drugs, paints, and oils. Foodstuffs of European origin were imported to the value of $118,329 in 1901, but only $87,675 in 1902, while similar imports from the United States increased from $493,078 in 1901 to $554,251 in 1902. This increase is due to frequent and easy maritime communication with the ports of New York, New Orleans, and Mobile, which has also "raised the percentage of Costa Rican products shipped to the United States, such as gold bullion, rubber, hides, and coffee." From Nicaragua 14,587 head of cattle were imported. Imports of gold coin in 1902 amounted to $250,000, of which $150,000 was consigned to the government and $100,000 to the Bank of Costa Rica.

Cuba.— The principal exports from Cuba to the United States in 1902 were sugar, tobacco, bananas, mahogany, and logwood. Imports into Cuba from the United States were: Wheat flour, valued at $2,059,876; agricultural implements, $45,304; corn, $827,538; carriages, $457,217; cycles, $12,320; cotton cloths, $208,039; wearing apparel, $158,313; builders' hardware, $322,500; sewing-machines, $97,355; steam-engines, $125,730; typewriting machines, $33,982; leather, $68,348; rosin, tar, etc., $28,576; turpentine, $30,154; oils, $586,946; beef, $9,105; tallow, $7,276; bacon, $379,188; hams, $505,757; pork, $316,383; lard, $2,197,928; butter, $26,624; cheese, $14,593; tobacco, $137,339; wood, $151,614; lumber, $877,880; and furniture, $261,683. Cuba's exports to all countries in 1902 were valued at $64,329,000, an increase of $1,051,000, as compared with those of 1901. The United States took 76 per cent of the exports, $49,498,000, an increase of $1,431,000 over 1901; England 9 per cent, $5,087,000, a decrease of $134,000; Germany 6 per cent, $3,967,000, a decrease of $272,000; Spain 2 per cent, and France 1 per cent. The island produced 880,000 tons of sugar in 1902–3; or nearly 30,000 tons more than in 1901–2; yet the value of the sugar exported in 1902 was less by $1,391,000 than in the preceding year. Tobacco exported in 1902 was valued at $25,404,000, an increase of $77,000. See CUBA.

Dominican Republic.— During the year ending 30 June 1902, exports to all countries amounted to $3,095,691.43. Those to the United States were valued at $2,500,000, and imports from the United States at $1,500,000. See DOMINICAN REPUBLIC.

Ecuador.— For the year ending 30 June 1902 trade with the United States was represented by exports valued at $1,500,000, and imports $1,400,000. See ECUADOR.

Guatemala.— Exports to the United States during the fiscal year ending 30 June 1902 were valued at $2,600,000; imports from the United States, $1,680,000. See GUATEMALA.

Haiti.— The value of exports to the United States during 1902 is given as $1,200,000; of imports from the United States, $2,700,000. The principal articles exported were coffee, cocoa, and logwood. Haiti imports from Great Britain considerable quantities of cotton and linen goods and hardware.

Honduras.— The total value of exports from this republic in 1902 was $6,170,353.27, a decrease of $12,670.10 as compared with 1901. But during the past four years Honduras has increased the value of her exports by $1,387,666.69, and the value of her imports by $2,777,161.42. The total value of imports during 1902 was $4,377,161.42. The United States took two thirds of the exports ($4,077,108.89), and supplied three fifths of the imports ($2,841,484.10). Other countries to which exports were sent: Great Britain, $778,293.60; Central American republics, $775,473.90; Cuba, $303,509; Germany, $136,214.54. Metals valued at $938,976 (23,235 ounces of gold, 1,010,204 ounces of silver, and 25,198 ounces of copper) were exported during the year. (In this paragraph the dollar mark means *peso*, standard "dollar" of Honduras; value $0.39 in 1892.)

Mexico.— The exports from Mexico for the fiscal year ending 30 June 1902 were valued at $156,168,145.66 silver. In the preceding year the amount was $148,659,001.71 silver. The largest items were precious metals, to the value of $68,897,126.17 in 1901–2; and of $81,376,319.78 in 1900–1. The imports form a study of special interest to American business men, as indicated in the following table:

IMPORTS OF MEXICO (VALUES GIVEN IN GOLD).

Source	Fiscal Year 1900–1901	Fiscal Year 1901–1902
North America	$35,201,400.35	$37,450,613.84
Europe	28,956,971.89	26,380,111.76
Asia	545,410.29	514,309.08
Africa	26,938.62	25,030.06
Central America	70,044.75	41,091.93
South America	140,212.27	156,101.38
West Indies	58,009.00	53,851.65
Oceania	84,466.12	35,239.73
Total	$65,083,453.29	$64,656,349.43

But Mexico's imports from the United States were valued at $35,189,955.85, in 1900–1; and at $37,435,099.29, in 1901–2, being nearly the entire amount credited in the table to North America: this statement may, therefore, be regarded as evidence of a decided improvement in the commercial relations of the United States with Mexico. European countries which supplied Mexican imports in the fiscal year 1901–2 were: Germany, to the value of $6,451,099.24; Austria-Hungary, $354,401.75; Belgium, $1,074,743.17; Spain, $2,719,909.77; France, $6,296,001.72; Great Britain, $8,266,096.33; Holland, $235,246.35; Italy, $397,450.06; Norway, $79,056; Portugal, $41,265.45; Russia, $3,062.83; Sweden, $49,789.77; Switzerland, $405,811.53; other countries, $16,177.25. Imports during the last six months of 1902 from all countries were valued at $36,973,133 gold; against $29,586,547 for the same period of 1901. Exports also increased, being valued at $93,254,675 silver for the last six months of 1902; or $19,990,745 silver more than for the corresponding period of 1901. Exports from Mexico to the United States during the calendar year 1902 were: copper, value in United States gold or silver, $14,373,820; coffee, $2,785,633; coal, $25,022; logwood, $18,206; sisal grass, $12,907,629; oranges, $90,534; hides and skins, $3,611,628; india rubber, $97,534; lead, $3,884,285; sugar, $8,624; tobacco leaf, $61,595; and mahogany, $394,720. Imports from the United States during the calendar year 1902: agricultural implements, value in United States gold or silver, $340,514; corn, $4,275; wheat, $59,551; wheat flour, $217,485; carriages, $1,429,573; cycles, $27,052; copper, $829,035; cotton, $3,142,223; cotton cloths, $219,476; wearing apparel, $439,032; electric and scientific apparatus, $852,373; iron and steel, $427,192; builders' hardware, saws and tools, $765,317; sewing-machines, $422,845; steam-engines, $1,099,806; typewriting machines, $163,521; leather, $13,573; boots and shoes, $680,607; rosin, tar, etc., $16,558; turpentine, $3,415; oils, $1,543,776; beef, $20,566; tallow, $30,990; bacon, $32,754; hams, $61,932; lard, $533,365; butter, $86,160; cheese, $50,288; tobacco, $242,666; wood, $611,161; lumber, $1,509,983; and furniture, $613,608. Imports into Mexico from Great Britain in 1902 were: cotton manufactures valued at $1,506,379.24; linen piece goods, $70,595.52; railroad iron, $1,556,008.83; and galvanized sheets, $405,695.35. Importations of textiles and woven goods were less in value by $843,755.48, as a result of the increased manufacture of such goods in the Mexican mills.

Nicaragua.—Exports to the United States for the year ending 30 June 1902 were valued at $1,900,000; imports from the United States during the same year, $1,300,000. The total amount of foreign merchandise imported into Nicaragua during 1902 was said to be considerably less in quantity and value than that of any of the preceding 10 years. British trade with this republic has declined, or has been transferred to the United States or Germany. Mahogany logs, shipped from the port of Bluefields in 1902, represented 6,759,325 feet of lumber, valued at $337,966 United States currency.

Paraguay.— Exports, during 1902, were valued at $3,252,650 gold; imports at $2,050,000 gold, 35 per cent less than in 1901. Exports to the Argentine Republic in 1902 amounted to $1,469,510, and imports from that country to $1,681,722. See PARAGUAY.

Peru.—In the first half of the year 1902 imports amounted to $7,391,681. Ores to the value of $8,526,632 were exported; the value of such exports in the previous year having been $8,259,319. Exports to the United States in the year ending 30 June 1902 were valued at $3,200,000; imports from the United States at $2,500,000. Exports to Great Britain in 1902 were: unrefined sugar, valued at $278,276.34; alpaca, vicuña, and llama, $1,266,144.49; copper regulus and precipitate, $661,399.57. Imports into Peru from Great Britain during 1902 were: Cotton manufactures to the value of $1,785,751.08; woolen tissues, $356,985.61; worsted tissues, $125,285.62; railroad iron, $225,541.01; and wrought and cast iron, $171,063.62.

Salvador.— Exports in 1902 were valued at 10,278,151.98 *pesos,* and imports at 2,747,385.08 *pesos;* value of a *peso* in United States gold or silver being $0.384. The imports were chiefly from Great Britain, the United States, and Germany. In the fiscal year ending 30 June 1902, exports to the United States amounted to $600,000; and imports from the United States to $890,000. Coffee was exported to Austria, Holland, and Norway; sole leather to Cuba; manufactured tobacco to Curaçao; indigo to Chile; Ecuador, and Peru; and to Spain, Salvador sent indigo, coffee, and manufactured silk.

Uruguay.— The exports in 1902 were valued at $32,549,483; and the imports at $23,757,471. During the six years from 1897 to 1902, the exports of this republic exceeded the imports by $44,485,150. Exports to the United States, during the fiscal year ending 30 June 1902, were valued at $2,500,000; and imports from the United States at $1,500,000. Imports into Uruguay from Great Britain during 1902 were: Cotton manufactures, to the value of $2,097,426.21; woolen tissues, $128,105.35; worsted tissues, $213,843.11; iron (bar, angle, bolt, and rod), $48,641.56; railroad iron, $16,071; and galvanized sheets, $215,770.22.

Venezuela.— Exports through Puerto Cabello in 1902 were: 374,786 cattle hides; 11,205 deerskins, and 70,053 goatskins; the United States being the principal purchaser. Imports into Venezuela from the United States in 1902 were: Agricultural implements, valued at $1,694; carriages, $13,620; cycles, $462; cotton cloths, $460,888; wearing apparel, $17,328; electric and scientific apparatus, $28,320; builders' hardware, $22,682; leather, $27,406; rosin, tar, etc., $20,341;

turpentine, $3,488; oils, $108,870; hams, $31,154; lard, $298,888; butter, $84,363; lumber, $1,946; and furniture, $8,555. Cotton manufactures to the value of $911,440 were imported during 1902 from Great Britain. Complete statistics were not prepared owing to the disturbances in the country. A statement of the foreign commerce during other years will be found in the article VENEZUELA.

Consult: 'Monthly Bulletins' of the International Bureau of the American Republics from July 1902 to July 1903, inclusive.

MARRION WILCOX.

Express Service. The creation and development of express service in the United States, and the extension of the American express system, under American control, throughout the length and breadth of the civilized world, and beyond, offers positive, convincing proof of unique native constructive and administrative genius along the lines of greatest utility to mankind.

One of the most prominent, successful, and progressive express companies, now operating on every continent, began, some sixty years ago, with a simple service for delivery of packages between a few eastern and western points. To-day, the same organization has, in addition to traffic in the United States, British North America, and the Latin-American republics, at least a dozen agencies with commodious quarters on leading thoroughfares in principal European cities, each fully equipped with men, wagons, and horses for the most rapid and effective express service.

As part of its routine business, the company is in touch with thirty of the world's largest banking institutions and has shipping and banking correspondents at all large cities and ports in both hemispheres. As a means of comparison with express conditions of half a century ago, when the system was merely an adjunct to the railroads, a brief outline of the work now being carried on in progressive express companies will be of interest. Since the express plan first began, in 1838, the situation of the railroads toward the express companies has, by mutual consent, and to meet ever-growing demands, been entirely reversed. The railroads, in their own interests, so far as carriage of express freight is concerned, are now adjuncts of the express companies.

The most modern American express service, when conducted on a large scale, usually includes, in addition to conveyance of ordinary merchandise packages, the following special features:

Travelers' cheques, letters of credit, sight drafts, money orders, money transfer by cable and telegraph, payment of taxes, dues, etc., for nonresidents, conveyance of valuables and securities, collection of accounts, collection of notes, drafts, and C. O. D. parcels, purchase of goods, household supplies, books, articles, or commodities, rare or otherwise, and the performance of every other legitimate commercial, financial, or other transaction requiring the service of a personal representative of intelligence and discretion.

The "cheque" system has been so perfected that travelers in foreign countries save time and avoid delay by their use, as they are promptly recognized and cheerfully cashed or accepted by the principal hotels, steamship and sleeping-car companies, by many railroad companies, and by merchants, shopkeepers, and others, in settlement of accounts. Travelers often avoid loss of time in specially visiting banks to obtain funds for such expenses, as well as the delays resulting from inability to obtain money on Sundays, holidays, or fête days, or before or after business hours.

For those traveling in the United States, Canada, Mexico, Central and South America, these cheques afford the advantages of a secure and convenient means of carrying funds immediately available, combined with the avoidance of delays, of the risk of loss of money by fire or destruction, and of the annoyance of negotiating personal checks in places where such may be unacceptable. Being cashed by agents of the companies and by banks in all the principal cities and pleasure resorts of the United States, the Canadas, Mexico, Cuba, Central and South America, accepted in payment of fares by the principal steamship companies and many railroad companies throughout the United States, and received by agents and conductors of the Pullman Palace Car Company and by many hotels in settlement of account, travelers cheques are found to be a most satisfactory form of credit for use during a tour.

"Letters of Credit" now form a usual express office specialty. These documents are drawn in sterling and are available in all parts of the world. Through the Letters of Credit system, cheques may be obtained from express agencies at all important points. Every foreign express correspondent has a cable address, also every express agency.

The "C. O. D" system and bank of account collection are among the useful developments of express service. "C. O. D." shipments are subject to collection of bill or invoice for the goods, with prompt return of proceeds made at a small charge for such service. C. O. D. shipments to foreign countries are usually made under the same system as applied to domestic points.

Several of the big express companies attend to the collection of accounts, bills, notes, drafts, etc., in any part of the commercial world. Collections in United States and Canada are effected with unusual promptness and at less risk and cost to payee than by other methods. Collections in foreign countries of drafts or deposits, or by powers of attorney, are undertaken by express companies through their own organizations in Europe or through banking correspondents. The proceeds of C. O. D.'s or collections are transferred by cable when patrons desire, with a charge for collecting, plus only the cost of cablegrams.

The transfer of money is another useful and much appreciated feature of express service. Purchases are made and commissions executed for patrons, in the quickest possible time, at places in United States, Canada, and Europe, by a special department. Besides attending to orders for the purchase or sale of goods and property, including household supplies, this department pays tax bills, redeems articles pawned, collects baggage at railroad stations, secures seats at theatres, berths on sleeping cars, staterooms on steamboats, passage and staterooms on European steamers. Rare goods or books or articles requiring exact matching, or the maker or seller of which is unknown, are obtained without annoyance or loss of time to patrons.

Imports and exports of every class and size are handled by express companies now, as a rule, this work being deemed part of their regular business. Bills of lading, bills of exchange and all other documents of that character are prepared and attended to from first to last.

Money orders and drafts are issued by several express companies for any amount, at the posted rate of exchange, in sterling, francs, lire, lei, marks, kroner, rubles, kronen, gulden, finmarks, Turkish pounds, Mexican dollars, local dollars, pesos, rupees, yen, and U. S. dollars on all parts of the commercial world.

The regular transportation service of express companies includes merchandise, parcels, produce, money, bonds, valuables, and baggage. The routes extend over 50,000 miles of railroads in the United States alone. Shipments are frequently made in through express cars, with burglar and fire-proof safes for valuables and iron express trunks for parcels, all in charge of special messengers, fully armed. The swiftest trains are almost invariably used for express service. The aim of the companies is to cover the ground in the least time at the lowest rates. They accept entire responsibility for loss or damage. Some express companies run special express trains to facilitate business during very busy seasons. Other companies have this feature as a permanent arrangement.

Novel and highly useful features of the most modern express service are the securing of ocean passages, European railroad tickets, and passports for patrons at a nominal charge. It is only necessary for those who desire to utilize express companies in this way to state their wishes — the companies do the rest rapidly, perfectly, and inexpensively.

So much for the work-scope of express companies to-day as compared with that of earlier periods. Before reviewing briefly the evolutionary processes connected with express service developments it may be well to mention what has been brought about through the use of express enterprise and by such methods as are peculiar to the service.

1. The creation of wagon service, and, in connection with this, special cars and trains for transportation of express matter at high speed.

2. The creation of transportation business for carriage to and from all advantageous producing points of game, poultry, fish, oysters, and fruit to localities where these commodities are not easily obtainable.

3. The creation of a novel method of selling goods for merchants by collecting on delivery the amount of invoice and returning cash to the shipper.

4. The creation of a method of collecting the proceeds of negotiable paper and assuming, for the time being, responsibility of indorsees.

5. The creation of an efficient means of safe transportation of moneys and valuables shipped by individual citizens and by firms, banks, railroads, and the government. In one year $4,000,000,000 have been shipped in the United States through the express companies in this manner.

6. The creation of a vast and perfect network of money-order agencies. The present number of these agencies is estimated at 40,000.

The creation of improved facilities for immediate transportation of foreign goods from ports of entry to destination. Heavy bonds are demanded by the government and given for proper execution of this service.

Origin and Evolution of the Express Idea.— The "Express" idea sprang from the system of sending parcels in care of coach-drivers, by stage-coach, and from the shipping of such parcels in care of captains, by coasting vessels.

When the railroads took the place, gradually, of the coaches, much parcel traffic was performed by means of the steam-cars. Then the conductors of these cars had to assume responsibility for safe-keeping. Eventually, this transfer overcrowded them with work. A division of duties naturally followed. Finally, the railroads insisted that their employes should chose between railroad and the supplemental delivery traffic.

The principal events following this decision were:

1838–9. The starting of an express company to operate in New England. Alvin Adams, who later began business for himself in New York, was with this company.

1839. "Harnden's Express" started between New York and Boston.

1840. "Adams' Express" began operations between the same points.

1840–45. Other expresses opened up business, extending service to Philadelphia, Baltimore, Washington, Buffalo, Pittsburg, Detroit, Chicago, Cincinnati, Louisville, St. Louis, and New Orleans.

The men most active in the new field at this time were William F. Harnden, William B. Dunsmore, Henry Wells, Edward P. Sanford, Samuel M. Shoemaker, Johnston Livingston, and William G. Fargo.

Almost all of the western transportation was carried on over the Ohio, Mississippi, and Missouri rivers, with their tributaries, which included canals then recently completed in several of the States to connect those rivers with the lakes.

From 1840 the construction of railroads continued uninterruptedly, express business expanding in proportion. Then came the inauguration of express "continuous lines," enabling goods to be carried quickly between many points without transfers.

At this period people sent their letters by express as being safer than the government's mail service. In course of time the authorities at Washington protested, and finally prohibited by law the private conveyance, without United States contract, of private letters.

1848. The stampede of gold-seekers, 1848–9, to California, brought out a great extension of the express system. Money and gold-dust were transmitted direct from the coast to eastern points through the express companies, many new agencies being established for the purpose.

1854. In this year a consolidation of express interests took place. "Adams & Co." bought up and worked several minor eastern routes and secured the right to much southern traffic.

During the same year the "American Express Co.," first established in 1841, was formally organized, to operate from the east to the far west.

The "United States" express also came into existence in 1854 to operate along the New York & Erie railroad and the route running westward.

1854–5. About this time "Wells, Fargo & Co." were organized. They started the famous "Pony Express" and several stage lines. Other firms competed in these special forms of rapid transportation.

1855. The "National" Express Co. began operations in this year, with routes between New York, Albany, Troy, Saratoga, Whitehall, Rutland, and Montreal.

1858. Wells, Fargo & Co. and the Pony Express lines organized the "Overland Mail Co.," which, until the completion of the Union Pacific railroad, carried the whole of the United States mails between the Missouri river and the Pacific coast. By this time the express had become a recognized necessity in the commercial and individual transactions of the country. Its lines had amplified in every direction. It had attracted to itself sufficient capital to place it on a firm financial basis. Obligations to insure the safe and speedy transmission of merchandise, valuables, and money were readily assumed. When loss or damage occurred, due reparation was promptly made. Thieves were and are, to-day, followed up by them until caught and punished.

1861. Henry S. Plant and associates organized the "Southern Express Co.," which operated principally in the southern States.

1861–5. Upon the breaking out of hostilities, the express was the only means of communication between soldiers in the field and their friends at home. Government securities, being purchased largely by the people, were sent by government through the express, it being officially recognized that, during that critical period, the express was much safer than the official mail service.

After the war a contract was made by the United States government with the Adams Express Co., acting for itself and other companies, to transmit all securities and moneys of the government by express.

1865–1905. This period represents a phenomenal growth of the express movement. The present organization of the great companies, each with the experience of half a century to guide it, is practically perfect in its workings and labors continuously at high tension to keep even pace with calls which increase day by day. As railroad and steamship facilities become more and more complete the pressure becomes greater.

The routes now aggregate over 250,000 miles. The total number of packages handled per annum has reached nearly 150,000,000. The estimated total of men employed is 75,000, with 20,000 horses and 10,000 vehicles. The capital represented in this line of commercial activity is now at least $100,000,000.

Expressed Oils, in chemistry, oils obtainable from bodies by pressing, to distinguish them from mineral and essential oils, which last are obtained by distillation.

Expulsion. Usually this word is used to describe the act of depriving one or more members of a political or corporate organization, or of a society, of their right of membership. The act is frequently brought about by a vote of the organization or society after the submission of a committee report, for some violation of duty or some other offense rendering such member or members, in the opinion of their associates, unfit or unworthy.

It is provided in the Constitution of the United States that the members of the Senate or House of Representatives may expel members of their respective bodies, by a two-thirds vote, for disorderly conduct.

Corporations have the right of expulsion in cases where good order and proper control make the exercise of such power essential as, for example, (1) when the offense is not within corporate duties, but nevertheless disgraceful or infamous, or (2) when the offense is against his duty as a corporation member or officer or director, or (3) when the offense is of such a character as to infringe corporation rules and the statutes at the same time.

Before a person can be expelled from a corporation or society for disgraceful conduct outside of the jurisdiction of such organizations, a previous conviction by jury is necessary before expulsion. If the offense is against or in violation of corporation or society rules or duties, a trial and conviction may be had before the authorities of the organization.

The word "expulsion" is also used to describe the ejection of people from meetings when they create a disturbance or otherwise make their presence obnoxious. Those who convene meetings have, in the eyes of the law, the right to expel objectionable persons, providing they only use as much force as is necessary for the purpose.

Club members are not liable to expulsion for striking fellow members, refusing to submit to arbitration, refusing to pay awards of arbitration, or refusal to pay dues after illegal suspension.

Non-members of any organization, if present at any meeting of such organizations, are liable to expulsion.

The Constitution of the United States provides that Federal judges cannot be expelled from their posts during good behavior. See DISFRANCHISEMENT.

Expunging Resolution. See CENSURE, CONGRESSIONAL.

Extension, in physics and metaphysics, that property of a body by which it occupies a portion of space. Extension is an essential as well as a general property of matter, for it is impossible to form a conception of matter, however minute may be the particle, without connecting with it the idea of its having a certain bulk and occupying a certain quantity of space. Every body, however small, must have length, breadth, and thickness; that is, it must possess the property of extension. Figure or form is the result of extension, for we cannot conceive that a body has length, breadth, and thickness without its having some kind of figure, however irregular. In logic, extension is the extent of the application of a general term, that is, the objects collectively which are included under it; thus European is more extensive than French, Frenchman, German, etc. Matter and mind are the most extensive terms of which any definite conception can be formed. Extension is contrasted with comprehension or intension. See PHYSICS.

Extension, University. See EDUCATION; UNIVERSITY EXTENSION.

Extension Teaching. See HOME EDUCATION; UNIVERSITY EXTENSION.

Extenuating Circumstances, in legal practice, those circumstances, in connection either with the position of the prisoner or with the act alone, which are taken into consideration by the court in mitigation of the punishment. The previous good character of the person convicted may always be proved as a circumstance giving him some claim to leniency of punishment. Besides character, there are other circumstances, the presence of which in a case sometimes serves to mitigate the sentence, sometimes to take the act done out of the category of crime altogether. One is youth. Thus, no act done by any person under seven years of age is a crime. Defective mental power in the person convicted will always be considered in determining the severity of his sentence. Such disease of mind as prevents a man from knowing that the act he does is wrong will excuse him from the consequences of an act otherwise criminal. Drunkenness, when voluntary, is not held an extenuating circumstance, but if a man is made drunk by the fraudulent administration of drugs, and while under their influence kills another, not knowing what he does, the act is not a crime. It is a good excuse for persons charged with crime that they have been compelled by others by threats of death or great violence to do the criminal act; and the acts of a married woman in presence of her husband are presumed to be done under his coercion, and so, unless the presumption is rebutted, will be excused. Ignorance of the law is no excuse for an offense. Nor, in general, will ignorance of facts be a good excuse, though in particular circumstances it might form a valid defense. Sir James Fitzjames Stephen states, in language purposely vague, to represent the vagueness of the law, a principle under which the stress of necessity is held to excuse acts otherwise criminal. He says: «An act which would otherwise be a crime may in some cases be excused if the person accused can show that it was done only in order to avoid consequences which could not otherwise be avoided, and which, if they had followed, would have inflicted on him or on others whom he was bound to protect inevitable and irreparable evil, that no more was done than was reasonably necessary for that purpose, and that the evil inflicted by it was not disproportionate to the evil avoided.»

Extinct Animals. Many animals which inhabited the earth in bygone periods have entirely disappeared, leaving not even a modern representative of their race. Others, no doubt, were known to pre-historic peoples, concerning which no record has come down to us. But, within the period of recorded observations, many animals have lived and died out; various causes contributing to their extermination, not least among these being the presence of mankind. Man reconstructs the face of the earth to suit his needs: he cuts down forests, plows or burns over prairie lands, changes the course of rivers, drains the swamps, and thus destroys the natural environment of many of nature's wild children. Then, too, he destroys creatures directly; he kills them for food, for clothing, or for other utilitarian purposes; he hunts them because he fears them, as dangerous foes to himself, or to his agricultural pursuits; he destroys them for his sport; and, finally, he draws them from feral conditions by domestication. Not only thus does man directly injure the wild creatures; but his coming, accompanied by exterminating influences, kills out certain other creatures. These, when man has destroyed their natural prey, practically die of starvation before they can adapt themselves to changed conditions. Then the domestic dogs, cats, etc., help on the work of slaughter in certain ways, by preying upon wild life.

That pre-historic man was partially responsible for the extinction of certain animals, scientists are agreed; but they are also assured that except in the cases of the horse, the camel, and perhaps the domestic dog, the extinction was due more to their inability to adapt themselves readily to the changes of climate of that remote time, than to human agency. The wild progenitors of the horse and camel have not been known in historic times. That aboriginal man in Europe aided the elemental forces in their work of destruction, by hunting to death the mastodon, and the great cave-haunting lions, bears and hyenas, and other huge creatures of his time, is most probable; but in America this is not at all likely to have been the case.

Since the earliest records were made, however, various species have been eliminated from the European fauna; many from that of the other continents as well. In the days when the Romans fought the Dacians, various members of the cat family were common along the Rhine-Danube frontier, among them, lions, tigers, leopards, and wild-cats. They found also the great herds of wild cattle, which have entirely vanished. The ibex, too, is gone, and, but for the protective legislation, the chamois and the deer would have been exterminated, as well. The bear, the beaver, the wolf, and the wild boar, have all gone, within the last 10 centuries, from Britain, the wild-boar, which was hunted by royal cavalcades, disappearing at the close of the 17th century.

Records concerning Asiatic animals show few cases of extinction except those of a few cases of a species of sea-cow native to the Commander Islands, off the Kamchatkan coast. This animal, the rhytina, was pursued for its flesh, chiefly, and, so far as is known, the last survivor was killed in 1768. Among the same islands lived the now extinct Pallas's cormorant, a great bird also exterminated because of its edible quality.

Animals which are restricted in habitat to small islands seem liable to suffer from the inroads of man, more surely and swiftly, because they have no adequate means of escape, many such examples being furnished of birds whose power of flight is limited. Such species, especially in the Australasian and South Sea islands, have been in almost all cases, destroyed; notably several representatives of the moa tribe in New Zealand, the dodo, the solitaire, and certain parrots, rails, and fowls. The disappearance of the gigantic edible tortoises from the islands of the Indian Ocean and from the Galapagos, presents another striking instance of the extermination of animals owing to man's depredations.

Both Africa and America have presented fields for indiscriminate slaughter. In the former continent, where once there roamed great herds of antelopes, countless buffaloes and elephants, the slaughter has been so great since the middle of the 19th century as to make many of these denizens of plain and forest extremely rare, if not altogether extinct. The search for hides was perhaps the strongest destructive force; but the European hunters for "big game," and their followers, have done much in the same direction. The mountain zebra, the quagga, and various species of antelopes are examples of this; while the giraffe, to escape entire extinction, has retired to almost inaccessible regions in the Kalahari Desert and northward.

As for America, with her long list of lost species, most people are more or less acquainted with the efforts that have been made (and sometimes with signal success), within the past few years, to save, by protective legislation, such of her native birds as are still found; and to prevent the wholesale slaughter of her wild denizens of field and forest. The best-known example of extinction is furnished by the bison (q.v.), which roamed in vast herds over the grass lands, until it was destroyed by hide-gatherers; so that now there are no wild bison except one small herd, carefully protected by law, dwelling beyond the North Saskatchewan River. The American sea-elephant and the monk-seal are also practically gone; and the long lists of birds, from the great auk and the "passenger pigeon" to the California condor, give evidence how much this continent has been depleted as to its wild life. Many fishes, too, have decreased or wholly disappeared; and there is no doubt that, but for timely protection, many species, now small, would soon follow these vanished representatives of the earlier fauna, and swell the already lamentably long list of extinct animals. See SPECIES, EXTINCTION OF. L. H. HELLER,
Dewitt Clinton High School, New York City.

Extinction of Species. See SPECIES.

Extra-uterine Gestation. See PREGNANCY.

Extract, a term to denote all that can be dissolved out of a substance by a specified menstruum, such as water, alcohol, ether, etc. In modern pharmacy the term is applied to two kinds of preparation from vegetables. One is obtained by digesting the plant in water or other solvent, and evaporating or distilling away the excess of solvent till the extracted matter is sufficiently inspissated. The other is obtained by bruising the plant in a mortar, separating the juice, warming it till the green coloring matter separates, and filtering it off. The juice is next heated till the albumen coagulates, and again filtered. The juice is now evaporated to a syrup, the green coloring matter added and well mixed, and the evaporation is thereafter continued till the required concentration is attained. Extracts must be capable of being redissolved, so as to form a solution like that from which they were derived. Extracts are used in cookery, medicine, and the manufacture of perfumery.

Extract of Meat is a soft, yellowish-brown, solid or very thick syrup, which is employed as a portable soup. It is now manufactured on the large scale by processes proposed by Liebig. Finely chopped flesh is exhausted with water, the extract is heated, when, at 133° F., albumen coagulates; afterward the blood coloring matter also separates, and when these are removed and the clear liquid is evaporated at a low temperature, the extract is ready. This substance has a characteristic odor of roast meat, has a strong taste, dissolves in water, and forms a not unpalatable soup. It contains no fibrin, gelatine, albumen, or fat, but creatine, inosic acid, and other organic bodies are present, and it is especially rich in potassic salts and in phosphoric acid. It has the invaluable property of not spoiling by keeping; and it has been strongly recommended for its nutritious qualities; but its price limits the sale, and there is, besides, a dislike to food from other sources than perfectly fresh and new meat. It is very useful, however, for travelers, for troops, and for all persons who have to carry supplies of food about with them, or to prepare it rapidly.

Extradi'tion is the surrender of a criminal who has escaped from a territory under one government and taken refuge in a territory under another government. Extradition has two specific meanings in the United States. In the first place it refers to the surrender by one State government of a criminal who seeks asylum from another State of the Union in which he is held to be guilty of a heinous crime. (See EXTRADITION, INTERSTATE.) In the second place, it refers to the surrender of a criminal by one nation to another. The demand for extradition made by one nation of another is a matter of international law, and implies merely the control to be exercised by one nation over the right of affording asylum claimed by another. The Jay Treaty of 19 Nov. 1794 with Great Britain specified for powers of extradition during a period of 12 years. After its expiration in 1807 no provisions for international extradition were renewed until 1842 when the Ashburton treaty of 9 August of that year with Great Britain was concluded, in which extraditable offenses were enumerated. France on 9 November was the next country to enter into a treaty of extradition with the United States, since when treaties have been arranged with some 24 foreign governments providing for the mutual extradition of criminals, fugitives from justice, charged with heinous crimes, among which are enumerated robbery, burglary, arson, rape, embezzlement and the making and circulation of counterfeit money. In order to justify a claim for extradition, it is necessary to establish that the supreme political authority in the country where the crime has been committed has made a demand for the criminal's surrender; that an inquiry has been made into the facts of the case by a judge or United States commissioner, under direction of the President, in cases where the demand comes to the United States government from abroad; that a complaint be made on oath before the judge or commissioner; that a warrant be issued by the judge or commissioner for the apprehension of the party charged; that the charge be supported by suitable evidence; that a certificate be sent to the President of the United States signed by the commissioner, and stating that the charges are sufficiently well grounded to warrant a surrender; that such certificate so satisfy the President that he grant the writ of surrender.

The British extradition act of 1870 makes special provision that no criminal shall be surrendered for a political offense, and that the criminal shall not be tried for any but the crime of which he was demanded. In 1890 an extradition treaty was ratified between Great Britain and the United States extending somewhat the list of extraditable offenses in the direction of the commercial crimes of fraud and embezzlement. Consult: Moore's 'Treatise on Extradition and Interstate Rendition' (1891).

Extradition, Interstate. The New England Confederation of 1643 provided for mutual extradition of criminals between the different provinces; the Articles of Confederation did likewise; and the Constitution provides for it between the States, which are independent countries in all save the functions they have resigned to the general government. But the wording of the provision, though as definite as it can safely be made, leaves room for the widest difference in construction, and the evasion of the mandate in a large share of the cases that arise. It is: "A person charged in any State with treason, felony, *or other crime*, who shall flee from justice, and be found in another State, shall, on demand of the executive authority of the State from which he fled, be delivered up, to be removed to the State having jurisdiction of the crime." But must the offense be a crime by the law of the State requisitioned as well as of the State demanding? The judicial decisions say decidedly no — that "the obligation to surrender the fugitive . . . is the same as if the alleged act was a crime by the laws of both." On the other hand, the State executives, for obvious reasons, have stubbornly refused to tie their hands from exercising discretion, and have again and again acted on the theory that the offense must be a crime by the law of their own State. Thus, in the Dorr Rebellion (q.v.), Gov. Cleveland of Connecticut refused to extradite Dorr — though Dorr was actually using Connecticut soil to organize an attack on Rhode Island — on the ground that the latter's treason laws were not valid outside itself; and Gov. Seward of New York refused to surrender persons charged with stealing slaves (though his predecessors had done so), on the ground that it was not a crime by New York law, by common law, or the common consent of civilized nations. Even the principles of decision are not agreed upon. In some States the courts hold that the courts of the State making the demand are entitled to decide as to the sufficiency of the cause; in others their own courts make their own law without regard to that of the other States. Still another question is, whether the governor has any discretion in the matter, supposing his State law to demand extradition. The answer is somewhat startling; it is, that the governor legally has no discretion, that he is imperatively bound to issue the warrant, but if he does refuse, there is no power to compel him and no punishment for the refusal. The Constitution, in other words, has issued an imperative mandate with no provision for its enforcement. Indeed, it is difficult to see how there could be any; the only remedy being a State impeachment of its executive for malfeasance, which is out of the question in such cases. The forms of interstate extradition are provided in the act of 1793. The accused must be indicted in the State where the offense is committed; if the magistrate before whom the charge is brought is satisfied of its truth, he issues a warrant for the arrest of the criminal, and a copy is forwarded to the executive of the State, who makes requisition for the fugitive's surrender on the executive of the State to which he has fled. If the latter is satisfied of the legality of the process and the sufficiency of the evidence of guilt, he is to issue a warrant for surrender; but habeas corpus proceedings may always be interposed. The expense of the proceedings and transportation is borne by the State making the demand.

Extraordinary Ray. See LIGHT.

Extravagan'tes, two collections of decretals and constitutions of popes which were made up subsequent to 1317. Before the *Extravagantes* the Canon Law comprised the *Decretum* of Gratian (1234), the *Liber Sextus* (1298), and the *Clementinæ* (1317). No further collections were made by papal command, nor were any further collections officially promulgated; nevertheless, two collections were made by jurists, the *Extravagantes* of John XXII., and the *Extravagantes Communes;* and these, though lacking official promulgation, came in time to be recognized as part of the Canon Law. The *Extravagantes* of John XXII. consist of constitutions of that Pope only; the *E. Communes* comprise decretals of several popes between 1298 and 1484. The *Extravagantes* are so called because they wander out beyond (*extravagantur*) the limits of previous collections.

Extravaganza, ěks-trăv-ạ-găn'zạ, in music and the drama, a species of composition designed to produce effect by its wild irregularity and incoherence; differing from a burlesque in being an original composition and not a mere travesty. See DRAMA; STAGE.

Extravasa'tion, in contusions and other accidents, occurs when blood vessels are ruptured by the injury, and the blood finds its way into the neighboring tissues. A good illustration may be found in an ordinary bruise, when the part becomes blue in consequence of the vessels having been ruptured, and blood having escaped into the tissues. Extravasation in the cranium is a most serious accident, as the pressure on the brain which is the result often produces death very rapidly. The term is, however, applied to the escape of any fluid into the tissues from the vessels or cavity containing it.

Extreme Unction, a sacrament of the Roman Catholic Church for the bodily and spiritual comfort of the sick whose death is deemed to be imminent. The words of the apostle St. James in his epistle, ch. v., "Is any among you sick," etc., relate to this sacrament. The unction therefore is administered to the sick, and to those only who are in danger of death from sickness or from injury or accident; hence, it is not administered to persons under sentence of death, nor to those about to undergo a dangerous surgical operation, or the like; neither is it administered to children who have not reached the age of reason; for the principal end of this sacrament is, not restoration of bodily health, but forgiveness of sins. "If he has committed sins they shall be forgiven him." In the passage from St. James are found all the essential conditions of a sacrament, namely, the "outward sign," to wit: the anointing and the prayer of faith; and the "inward grace," typified by the outward sign, namely, forgiveness of sins. The divine institution of this sacrament is implied in the words of the gospel of St. James where it recommends its use and declares its efficacy for the remission of sins. Nevertheless extreme unction is not administered save after the person has made confession of his sins and received absolution in the sacrament of penance. In administering extreme unction the priest, with olive oil that has been blessed by the bishop, anoints the organs of the sense, pronouncing at each anointing the words, "By this holy unction and by his most tender mercy may the Lord forgive thee whatsoever sin thou hast commited by sight" (*per visum*), or "by hearing" (*per auditum*), etc.

Exuma, ĕks-oo'mä, **Great** and **Little,** two of the Bahama Islands. The Great Exuma is 30 miles long and 3 miles wide, and has a good harbor. Little Exuma has also a good harbor. The two islands together with Exuma Keys have an area of about 110 square miles. Pop. 2,374.

Eyas, ī'as, in falconry (q.v.), a hawk reared from the nest.

Eyck, īk, **Hubert van,** Flemish painter: b. Maaseyck, near Liège, Belgium, 1366; d. Ghent 18 Sept. 1426. It has been claimed that he and his brother Jan were the inventors of oil painting. For transparent and brilliant coloring and minute finish their works have never been surpassed. Their masterpieces are for the most part in Ghent, Bruges, Antwerp, Berlin, Munich, and Paris. The only painting that can now certainly be assigned to Hubert is the altarpiece with folding doors, 'The Adoration of the Lamb,' begun by him and finished by Jan, and afterward presented to the Cathedral of St. Bavon, Ghent, where only the two central divisions now remain, the wings being in the Gallery at Berlin, with the exception of those representing Adam and Eve, which are in the Brussels Museum.

Eyck, Jan van (also called **Jan van Brugge,** or **John of Bruges**), Flemish painter: b. Maaseyck about 1381; d. Bruges 9 July 1440. Hubert (q.v.) gave him his first instruction in the principles of the art, and his talents were so rapidly and vigorously developed that he soon surpassed his brother. The two resided at Bruges, then much frequented by the noble and the wealthy on account of its flourishing commerce. About 1420, or soon after, they went to Ghent for a considerable time, to execute together a work which Jodocus Vydt, a Flemish noble, had engaged them to do. This is the celebrated 'Adoration of the Lamb' for the cathedral of Ghent; a painting which contains above 300 figures, and is a masterpiece. It is painted on wood, with side panels which contain the portraits of the two artists and of their sister Margaret (q.v.), likewise a painter.

The reputation of this celebrated painter became very notable, even during his lifetime, by his great share in the introduction of oil painting; the original invention of which has been incorrectly ascribed to him by many. It was a general custom, before his time, to have for the background of the picture a flat gold ground, from which the figure stood out without perspective, as may still be seen in numberless works of earlier date. Van Eyck followed this practice in his earlier efforts, but, as he made further advances in his art, conceived the idea toward which there had been hitherto only some distant advances of giving a more natural grouping and perspective to his figures by a natural background. In this he succeeded so eminently, as many of his still remaining works prove, that he may be called in this respect the father of modern painting, since he gave the art a new turn and impulse, and laid the foundation of that high degree of improvement which it afterward attained in the brightest era of the great masters who succeeded him in the Netherlands and in Italy. In the art of painting on glass he is considered as the author of the mode of painting with colors delicately blended and yet so firmly fixed that obliteration was impossible — an object before attained only by joining together (in mosaic) several small panes of different colors. The school of which he was, in some measure, the founder, does not yield in celebrity to the best contemporary or succeeding artists, although it must be allowed to be often defective in the representation of the extremities of the human body — a fault occasioned by that excessive delicacy which prevented the study of naked forms, and of anatomy in general. On the other hand, the face, dresses, grouping, distribution of light and shade, are always superior, and the color brilliant and splendid, in the works of this painter and most of his scholars. Many of his paintings are still preserved, either in churches and museums, or in private collections.

Eyck, Margaret van, Flemish painter, sister of Hubert and Jan van Eyck: d. about 1430. A 'Virgin and Child,' in the National Gallery, London, was formerly assigned to her, but in the catalogue of 1889 is attributed to an unknown painter of the Early Flemish school; and she is believed to have executed the miniatures in the missal of the Duke of Bedford.

Eye, August von, ow'goost fōn ī'ĕ, German historian and critic: b. Fürstenau, Hannöverschen, 24 May 1825. His 'The Kingdom of the Beautiful' (1878); 'The Life and Work of Albert Dürer' (1860), together with his studies in art developments and tendencies, have been widely read.

Eye, the peripheral organ of vision by which light and images from the outer world are received and from which these images are transmitted to the visual centres in the brain or its equivalent by means of nerve fibres.

Anatomy and Physiology of the Human Eye. — The human eye is situated within a quadrilateral pyramidal cavity, surrounded by bony walls, called the *orbit.* The bony walls separate the orbit from the neighboring cavities, namely, the intracranial, the frontal, the nasal, and the Highmorean antrum. The anterior open-

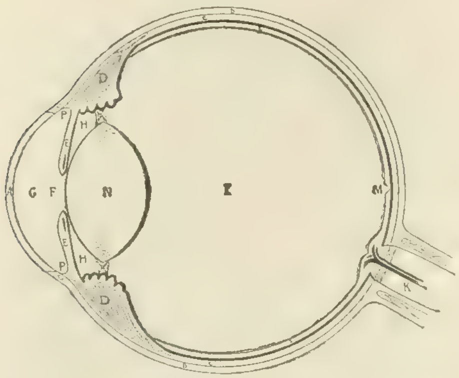

FIG. 1.

ing of the orbit forms the base of the pyramidal cavity; the apex lies in the depth and is penetrated by a number of openings for the passage of blood vessels and nerves. The bony rim of the anterior opening of the orbit is called the orbital margin. It is made up of very hard bone-tissue. Its upper, outer, and lower parts are more or less sharp and overhang the interior of the orbit slightly. The nasal part is rounded off toward the nose.

The walls of the orbit are formed by the union of seven bones of the skull and face. The upper wall consists of the frontal and sphenoid bones; behind its margin temporally it has a depression for the orbital lacrimal gland, near its nasal end there is a depression for the supraorbital artery and nerve and for the pulley through which the superior oblique muscle goes to the eyeball. The outer wall consists of the zygomatic and sphenoid bones. The lower wall, which is higher on its nasal than on its temporal side, consists of the supramaxillary, zygomatic, and palatine bones. The inner wall consists of the ethnoid, lacrimal, and sphenoid bones. All of the walls have openings and grooves for the passage of blood vessels and nerves. Where the supramaxillary and the lacrimal bones join together they form a bony canal for the lacrimal nasal duct.

At the apex of the orbit lies a round or oval funnel-shaped opening, the optic canal or foramen, through which the optic nerve comes from the brain; it runs slightly inward and upward. With this nerve, and underneath it, the ophthalmic artery enters the orbit. At the junctions of the outer wall with the upper and lower ones two fissures are formed, the upper one the sphenoid and the lower one the sphenomaxillary fissure. The ophthalmic nerve and vein, and the motor-nerves for the eye pass through the former.

The nasal walls of the two orbits run nearly parallel with each other, while the temporal walls converge toward each other. Therefore, the axes of the two orbits diverge towards their bases. The conformation and situation of the orbits and of their walls differ within certain limits very much in different individuals. They are sometimes so misshaped as to displace their contents and to interfere materially with comfortable binocular vision.

The periosteum of the orbital walls, which comes from the dura mater of the brain, besides covering the bones, furnishes numerous trabeculæ which hold the contents of the orbit in place, a sheath for the optic nerve, a serous capsule in which the posterior four fifths of the eyeball are encased and rotate (Tenon's capsule), and an anterior fascia-like diaphragm pierced by the anterior fifth of the eyeball. The posterior part of the orbit, besides blood vessels, nerves, and muscles, contains the orbital fat, which forms an elastic cushion on which the eyeball rests. Fig. 2.

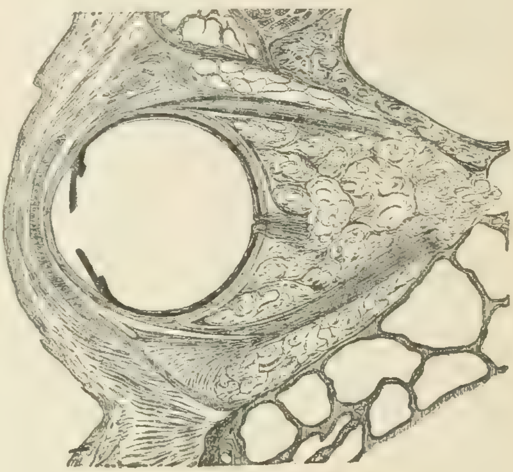

FIG. 2.

The eyeball itself consists of three membranes and several additional organs. The outer membrane, by which the shape of the eyeball is retained, has two parts of the cornea (horny membrane) (A, Fig. 1) and the sclerotic (hard membrane) (B, Fig. 1). The shape of the eyeball is nearly that of a sphere with the segment of a smaller sphere superadded anteriorly. The former (sclerotic) makes up about four fifths, the latter (cornea) one fifth of the eyeball. The former appears white, is very tough but elastic and translucent. The latter is, also, very tough and elastic, but perfectly transparent with a refractive index like that of water. The sclerotic consists of very dense connective tissue, similar to tendon-tissue, the fibres of which are interwoven in an irregular manner and form bundles. In a general way these bundles run in a meridional direction, but equatorial ones are always to be found anteriorly at the junction between cornea and sclerotic, and posteriorly where the optic nerve enters the eyeball. These fibres and bundles are held together by a cementing substance in which lie lymphatic canals and stationary cells. The sclerotic has but few and small blood vessels and nerves of its own, but gives passage to all the blood vessels and nerves which enter the interior of the eyeball or come from it. The former are the ciliary nerves, the optic nerve, and the ciliary arteries, the latter are the vorticous veins of which from four to six carry the blood away from the interior of the eyeball at or near its equator. Where the optic nerve enters the eyeball there is not one large opening for its admittance in the sclerotic, but the optic nerve fibre bundles pierce the sclerotic tissue separately. Thus this part of the sclerotic has a sieve-like appearance (*lamina cribrosa*). The tendons of the muscles of the eyeball are inserted into the sclerotic after having pierced Tenon's capsule.

The cornea is joined to the sclerotic anteriorly very much like a watch-crystal to its rim, that is the translucent tissue of the sclerotic slightly overlaps the transparent corneal tissue on the outer surface. The tissue of the cornea proper is a modified, perfectly transparent, dense connective tissue which consists of finest fibres united together by a cementing substance into bundles and these again into layers (*lamellæ*) which run more or less parallel with its surface. The layers are thicker in the posterior part and grow thinner toward the surface and finally form one perfectly compact layer, Bowman's or Reichert's membrane, on the outer surface. This may be looked upon as the basal membrane on which rests the outermost coating of several layers of epithelial cells. The inmost layer of these is single and is formed of cylindrical cells, then follow flatter and flatter cells outwardly, the outermost layer being true pavement epithelium, the cells of which never undergo a horny metamorphosis like those of the epidermis. The posterior surface of the corneal tissue proper is lined with a thin elastic vitreous membrane, Descemet's membrane, on which rests posteriorly a single layer of endothelial cells. In the cementing substance of the cornea lie very numerous lymph canals, von Recklinghausen's canals, which contain the fixed corneal cells (corneal corpuscles) in lacunæ-like enlargements. The cornea proper has no blood vessels; a ring of vascular loops enters its periphery only to the distance of one millimetre. Where cornea and sclerotic are joined the fibres and lymph canals of the one membrane pass over into those of the other. Here, also, a larger ring — like venous plexus, Leber's venous plexus or Schlemen's canal, is embedded, by which fluids from the anterior chamber are carried off. A large number of ciliary nerves enter the cornea at its periphery, are at first distributed in the corneal tissue proper, then having been divided into branches and just under Bowman's membrane into terminal fibres, they pierce this membrane and are lost in the epithelial cells.

Inside the sclerotic and loosely connected with it except at two points (the nerve entrance and the tendon of the ciliary muscle) lies the uveal tract, the vascular membrane of the eye. This membrane is divided into three distinct parts with distinct functions. The posterior one is the *chorioid* (C, Fig. 1); forward from it lies the *ciliary body* (D, Fig. 1); and in front of this the *iris* (E, Fig. 1). The chorioid begins around the entrance of the optic nerve and reaches forward beyond the equator of the eye. Inwardly it is lined by a very thin elastic membrane, the *lamina vitrea;* outwardly fibres of its tissue mingle with those of the sclerotic, leaving lymph spaces between them, *lamina suprachorioidea* and *fusca*. The tissue proper of the chorioid is made up of very loose connective tissue in which are embedded innumerable stellate pigmented cells and endothelial cells. The pigment in the stellate cells varies from almost no tint in the albino to jet black in the negro. In the loose connective tissue lie, furthermore, the innumerable blood vessels of the chorioid. The arteries coming from the short posteriociliary arteries and the veins, forming together the vorticous veins, lie in the outer two, the capillary blood vessels in the inner third of the membrane (Fig. 3). In the suprachorioideal tissue the long posterior ciliary arteries and the ciliary nerves run forward to the ciliary body. The function of the chorioid is the nutrition of the interior of the eyeball, especially of the outer layers of the retina, and the absorption of light.

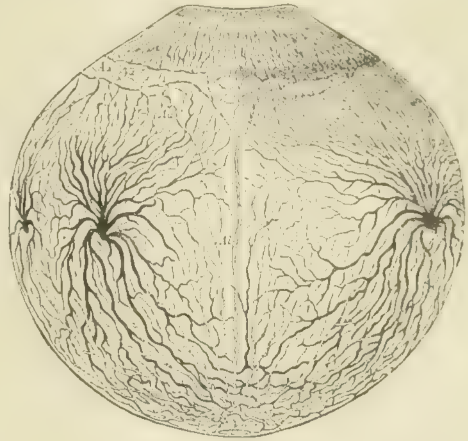

FIG. 3.

On the inside of the *lamina vitrea* lies a single layer of mostly hexagonal epithelial cells filled with pigment, the *pigment epithelium,* which though genetically belonging to the retina, must be looked upon as a gland-like organ interposed between retina and chorioid. Its cells send pigmented offshoots in between the outer parts of the rods and cones of the retina and by their secretion give the rods a slightly purplish tint, the retinal purple. This purple is continually bleached by the action of light and regenerated in the dark. Thus photochemic changes are produced, the exact value of which for the function of vision is as yet unknown.

Somewhat in front of the equator the chorioid becomes thicker, at first slowly and then more abruptly, and wrinkled, and thus the second part of the uveal tract in the ciliary body is formed (*pars non-plicata* and *plicata*). The thickening of the tissues is due to the addition of muscular tissue on the outside of the chorioideal tissue proper. This is the ciliary muscle or muscle of accommodation. Its anterior tendon is inserted into the corneo-scleral tissue inward of Leber's plexus, its posterior tendinous fibres are lost in the fibrous tissue of the chorioid. We recognize in this muscle two sets of fibres, one running meridionally on the outside, the other lying inward and forward running in an equatorial direction. The two act, however, together. In nearsighted eyes the former is more developed, in farsighted eyes the latter. The inner surface of the ciliary body which is represented by the chorioideal tissue shows about 70 meridional folds, the ciliary processes, on which microscopically a great many smaller wrinkles can be recognized and by which means the surface is immensely increased. These are covered by the continuation of the pigment epithelium and a layer of cylindrical unpigmented cells, the continuation of the retina, the retinal part of the ciliary body. The function of the ciliary body is twofold. Its muscular tissue governs the accommodation of the eye; the wrinkled inner surface is an immense secreting surface for the production of the aqueous and probably also, the anterior part of the vitreous body.

At the apex of the ciliary body and just inward from the tendon of the ciliary muscle, the third part of the uveal tract begins, the *iris*. This membrane lies in a plane almost at right angles with the one of the ciliary body. It has a round central opening, the pupil, which is the hole through which light reaches the interior of the eye and which is smaller when much light falls into the eye and larger under the reverse conditions. The tissue of the iris resembles that of the chorioid. It consists of a very loose, sponge-like connective tissue, richly supplied with stellate pigmented cells, and containing innumerable blood vessels. These come from the larger arterial circle at the periphery of the iris formed by the anastomosis of the branches of the long posterior and anterior ciliary arteries. They form a capillary network near the pupillary edge of the iris, the small iris circle. Both the anterior and the posterior surfaces of the iris show later in life circular folds and wrinkles, especially near the periphery, which result from the play of the pupil. Moreover, the anterior surface is studded with smaller and larger openings leading into small pouches, crypts of the iris. Posteriorly the iris is covered by the continuations of the two cell layers which cover the inner surface of the ciliary body. On the iris both of them are deeply pigmented so that without bleaching it is impossible to recognize the single cells. This pigmented layer reaches inward to the pupillary edge. The anterior surface of the iris is covered by endothelial cells. At its periphery the iris tissue receives fibres which come from Descemet's membrane and the innermost layers of the cornea, and which together form a network lying inside of the tendon of the ciliary body. This network of fibres which are partly covered by endothelial cells is called the pectinate ligament; the openings in it are called Fontana's spaces. Through this tissue the fluids passing out of the eye are filtered. The angle formed by the iris and corneo-scleral tissue is, therefore, usually termed the filtration angle of the eye. Around the pupillary opening and lying near the posterior surface of the iris a ring muscle is situated by the contraction of which the pupil is made smaller. A layer of spindle cells in front of the pigmented layer seems to represent an antagonistic pupil-dilating muscle. The function of the iris is that of a movable screen with a central opening, the size of which by reflex action regulates the amount of light which is to fall into the eye, the pupil contracting in strong and dilating in weak light. The pupil also contracts during the acts of accommodation and convergence.

Inward from the chorioid and closely applied to it lies the nervous membrane which receives the images, the expansion of the optic nerve, the *retina* (L, Fig. 1). This membrane consists of the optic nerve fibres to which are added nerve cells and neuro-epithelial cells, the whole held together by connective tissue, Mueller's fibres. The optic nerve (K, Fig. 1) having entered the orbit through the *foramen opticum*, and on its way to the eyeball, has three sheaths, the *dura mater* and *arachnoid* together forming the outer and the *pia mater* an inner sheath which closely invests the whole nerve and sends numerous trabeculæ into it which hold its fibre bundles together and in place. Between the sheaths lies the intervaginal space, a lymph-space communicating with the intracranial cavity and with the lymph-spaces in the eyeball. The dura mater and arachnoid together join the sclerotic where the nerve enters through this membrane, the pia mater ends where the nerve passes through the chorioid, unless we can look upon Mueller's fibres as its continuation. The double contoured nerve fibres coming from the chiasma lose their Schwann's sheath just before the nerve reaches the eyeball. Having reached the inner surface of the chorioid the fibres turn abruptly so as to cover the interior. This manner of distribution causes the nerve fibres at first to form a roundish elevation with a central depression, the optic papilla. This part consisting of conducting fibres only, does not perceive images and is known as Mariotte's blind spot.

The optic nerve fibres form the inner layer of the retina. The retina proper getting thinner and thinner reaches forward to the ciliary body where it ends with a serrated edge, *ora serrata*. It has a very complicated structure and including the pigment epithelium, has 10 distinct layers. The other nine are the rods and cones, the outer limiting membrane, the outer granular layer, the outer molecular layer, the inner granular layer, the inner molecular layer, the ganglion cell layer, the nerve fibre layer and the inner limiting membrane. The impressions received in the rod and cone layer are carried from neuron to neuron and finally back to the brain centres. The point of most acute perception lies opposite the center of the cornea, about 15° outward from and a little above the optic papilla. It is called the yellow spot (*macula lutea*) and has a central depression, the *fovea centralis*. Here the retina gets thinner on both surfaces till it consists but of a few nerve cells and conducting fibres, the rods have disappeared and the outer layer is formed of cones alone. The cones must, therefore, be considered as the organs of greatest importance in the act of distinct vision. From the neighborhood of the macula lutea to the ora serrata the proportion between rods and cones increases continually in favor of the rods. The retina is supplied with blood vessels in its inner layers only. They come from the central retinal artery and supply the retina only.

Close behind the iris lies the crystalline lens (N, Fig. 1), a lentil-shaped transparent body enclosed in a transparent capsule, the anterior half of which is thicker than the posterior one. The anterior capsule is lined with a single layer of cuboid epithelial cells which a little behind the equator of the lens grow longer and longer and form the lens fibres, long prismatic bands, of which the bulk of the lens tissue consists. These bands are arranged concentrically, new ones being added from the surface to the older ones which form a dense nucleus in the centre of the lens. With advancing age this nucleus grows larger, harder and less and less elastic. The lens is held in position by a ring of glassy tough fibres, the zonule of Zinn (O, Fig. 1) or suspensory ligament, which being firmly attached to the ciliary body and its processes, insert themselves on the anterior and posterior capsules near the equator. The origin of these fibres is still doubtful. The function of the lens is to focus images on the retina.

Behind the lens and supporting it in a cup-shaped depression, *fossa patellaris,* lies the *vitreous body* (I, Fig. 1). It fills the large posterior cavity of the eyeball. It is a perfectly transparent gelatine-like substance in which fine fibrillæ and a few wandering cells are found.

The space bounded by the inner surface of the cornea, *ligamentum pectinatum*, anterior surface of iris and anterior lens capsule, as far as it lies in the pupil, is called the *anterior chamber* (G, Fig. 1). The prismatic ring bounded by the posterior surface of the iris, the anterior part of the ciliary body, the zonule of Zinn and the peripheral part of the anterior lens capsule, is called the *posterior chamber* (H, Fig. 1). These two chambers are filled with a watery fluid, the *aqueous humor.*

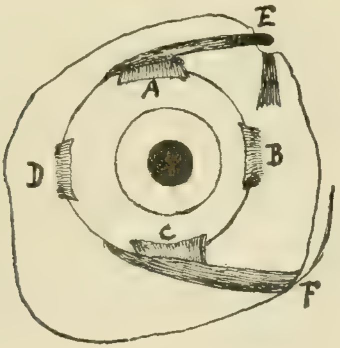

Fig. 4.

The eyeball within certain limits, can be moved in all directions around a centre of rotation by means of six *muscles* (Fig. 4). Five of these come from the apex of the orbit (Fig.

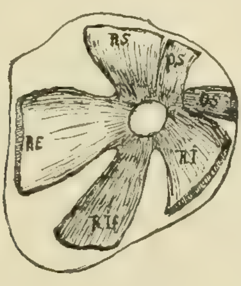

Fig. 5.

5). Four of these five, the recti muscles, run almost straight forward to their insertion on the sclerotic, namely, the superior, inferior, inner (nasal) and outer (temporal) rectus muscle. The fifth one, the trochlearis or superior oblique muscle, runs forward to the upper orbital margin, there passes over a pulley and returns to the eyeball from above in an oblique direction. The sixth muscle, the inferior oblique, springs from the lacrimal bone and running backward inserts itself on the eyeball in an oblique direction from below. The recti muscles turn the eye, the oblique ones roll it. By the single or combined action of these muscles the eye can be turned in all directions.

The *eyelids* are formed by two duplicatures of the skin, an upper and a lower one. The inner skin lying close to the eyeball assumes the character of a mucous membrane, the palpebral conjunctiva. It is folded over on the anterior third of the eyeball which it covers to the corneal periphery, bulbar or ocular conjunctiva. The fold of reversion, fornix or cul-de-sac, is very loose, so that the motions of the eyeball are not interfered with. When the lids are closed, the parts of the conjunctiva form with the cornea a closed sac, the conjunctival sac.

At the free margin of the lids, skin and conjunctiva merge into each other. This free margin has two edges, an inner sharp one and an outer rounded one; between them lies the intermarginal space, in which lie the eyelashes and the orifices of numerous glands. The stiffness of the lids is due to the very dense tarsal tissue plates which, semilunar in shape, form the inner layers of the lids, to which the palpebral conjunctiva is closely adherent. In this tissue and near its posterior surface lie the Meibomian glands which secrete a fatty substance the presence of which prevents the tears from running over the edges of the lids. In front of these the eyelashes, *cilia,* spring forth, short, strong, curved hair which interlock when the lids are closed. They live only about 100 days, and then fall out to be replaced by new ones. The lashes have the usual sebaceous glands and between them lie the so-called modified sweat glands of Moll. Between the outer skin and the tarsal tissue the fibres of the orbicularis muscle are embedded which when contracting closes the lids. The upper lid is rolled backward on the eyewall in the act of opening by means of its levator muscle which coming from the apex of the orbit is inserted on the upper edge and anterior surface of the tarsal tissue. From the orbital edge of each tarsal plate a non-striated muscular layer goes backward into the orbital tissue, Mueller's muscle. The opening between the lids is called the palpebral fissure. Where they join each other the lids form an outer, sharp angle, outer canthus, and an inner rounded angle, the inner canthus.

The eye, as far as it is exposed to the air, is kept moist and lubricated by the tear-fluid. The glands secreting it and the means of carrying the surplus away together are called the *lacrimal apparatus.* The tears are secreted by a number of acinous glands. The largest one lies in the orbit in the lacrimal fossa of the upper orbital wall. Right underneath it in the upper eyelid itself and down beneath the canthus in the lower lid smaller glands are situated, and still smaller ones are found all along the upper edge of the tarsal tissue of the upper lid, clear over to the inner canthus. All of these glands empty their secretion into the conjunctival sac by means of ducts. The fluid flows over the anterior surface of the eyeball and towards the inner canthus where the drainage apparatus is situated. Behind the inner canthus of the lids lies a round, dermoid body supplied with sebaceous glands and hair, the lacrimal caruncle, and in front of it a semilunar fold of conjunctiva, the remnant of the third lid in animals. When the stream of tears reaches the fatty caruncle it is held back and thus more easily sucked up. This is done by means of two capillary lacrimal canaliculi, which have their orifices (*lacrimal puncta*) in little papillæ at the edge of each lid near the caruncle. The sucking up of the tears is materially aided by a special muscle, Horner's muscle. The canaliculus in the upper lid runs in a slight curve downward toward the nose, the one in the lower lid upward. They meet behind the junction of the lids, the internal palpebral ligament, and empty their contents either singly or together into a larger receptacle, the lacrimal sac, from which in turn the tear-fluid is drained by the nasal lacrimal duct which opens on the lower floor of the nose.

The blood supply of the eye comes from a branch of the internal carotid artery, the ophthalmic artery, which gives off branches to the optic nerve sheaths, the orbital fat, the muscles of the eyeball, the lacrimal gland, besides the supraorbital, posterior, ethmoidal, and naso-frontal branches. From the muscular branches of the four recti muscles the anterior ciliary arteries pass through the sclerotic to the ciliary body and iris. Fom the ophthalmic artery directly or from one of its larger branches spring about 6 arteries which in turn split into about 20 branches and enter the sclerotic and the chorioid directly in a ring around the optic nerve entrance, called the short posterior ciliary arteries. Usually two of these branches run very obliquely forward through the sclerotic before reaching the uveal tract, the long posterior ciliary arteries.

The central retinal artery, which supplies the retina alone, comes from the ophthalmic artery, or one of its larger branches, enters the optic nerve near its entrance into the eyeball and then lies in its central canal together with the central retina vein.

The venous blood coming from the eye and orbit is collected into a superior and an inferior ophthalmic vein, both of which carry it to the cavernous sinus; a small portion is carried off by the temporal and facial veins.

The *nerves* of the eye, aside from the optic nerve, are motor, sensitive and sympathetic nerves and enter the orbit through the sphenoid fissure. The trochlearis nerve goes to the superior oblique muscle, the abduceus nerve to the external rectus muscle. The oculo-motor nerve, soon after its entry into the orbit, forms two branches. The upper one of these goes to the superior rectus muscle and to the levator of the upper lid. The lower one splits into three smaller branches for the internal and inferior rectus and for the inferior oblique muscle. This last branch forms the short root of the ciliary ganglion. The ophthalmic nerve (the sensitive nerve) a branch of the trigeminus gives off the supraorbital, naso-ciliary and lacrimal nerves. The naso-ciliary nerve forms the long root of the ciliary ganglion. Thus this ganglion from which originate the short ciliary nerves which go to the eyeball, contains motor, sensory and sympathetic fibres, the latter from the carotid plexus. The short ciliary nerves reach the sclerotic in a ring around the optic nerve entrance. The long ciliary nerves come from the naso-ciliary nerve (Fig. 6).

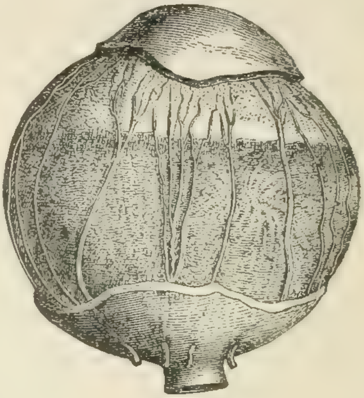

Fig. 6.

The optic nerve proper comes from the optic chiasma, the anterior commissure of the brain. The centres of vision are at present thought to lie in the occipital lobe of the brain in the cuneus and the region of the angular gyrus. From here fibres eradiate forward in the internal capsule to the pulvinar of the optic thalamus and are joined by fibres from the *corpora geniculata* and *quadrigemina*. These fibres together form the optic tract of each half of the brain. In the chiasma the two tracts join and partially cross each other, the smaller portion remaining uncrossed and going to the eye of the same side, the larger portion going to the eye of the opposite side.

Physiology.—As an optical instrument the eye has several refractive media. The main ones are the cornea and the crystalline lens. The curvature of the cornea, which is altered under special circumstances only, is not ideally spherical, but rather as if curved over a revolving ellipsoid. Therefore, most corneæ are asymmetrical in curvature, a condition which is called astigmatism. Rays of light impinging on the cornea are refracted so as to pass through the pupil; where they impinge on the crystalline lens by which they are farther refracted in such a manner as to come to a focus on the retina, on which an inverted image results. In order to change the focus of the lens so as to give clear images as well of distant objects, as of near ones, the eye is provided with the apparatus of accommodation. That is, it is enabled through the contraction of the ciliary muscle and the consequent increase in convexity of the lens to increase its refracting power and to shorten its focus or by relaxation to lengthen it. This faculty is gradually lost as age advances and at about 45 years of age accommodation for near objects can no longer be accomplished, *presbyopia.*

When an eye, perfectly at rest, focuses parallel rays on its retina it is called emmetropic. When in an eye, perfectly at rest, parallel rays are focused behind the retina, it is called hypermetropic or farsighted. When in an eye, perfectly at rest, parallel rays come to a focus in front of the retina, it is called a myopic or nearsighted eye. These differences depend chiefly on the axial length.

In astigmatism the asymmetry of the curvature of the cornea (or the lens) prevents rays of light from being focused in one point. As we can in this case usually recognize a principal meridian of lowest and one of highest curvature which generally lie at right angles to each other, we may find a number of combinations, as for instance the focus of the one principal meridian emmetropic and the other hypermetropic, or the one hypermetropic and the other myopic, etc. In consequence of astigmatism no clear images can be perceived by the retina of such an eye.

The whole area in which an eye, when steadily gazing at one point, can perceive objects, is called its field of vision. This has an irregular round outline and for white reaches upward and inward to between 60° and 70°, downward between 50° and 60°, and outward to 90° and more. The fields for colors are smaller in the following order: Blue, red, green. The binocular field is not as large as twice the monocular one, since the fields overlap at the nasal side to quite a considerable extent.

In binocular single vision the images must fall on the so-called identical spots in the two retinæ. When they do not, double vision, *diplopia*, results.

The perception of colors, a faculty which in man is congenitally wanting in about four pro mille (sometimes in one eye only), has been explained by a number of theories. That of Young-Helmholtz and the one of Hering assume special nerve cells for the perception of different colors. Oliver and others believe in the central location of color perception. Others believe in a combination of the two arrangements.

Comparative Anatomy.— The eye of man is a comparatively perfect visual organ and optic instrument. The farther we go down the scale of the animal kingdom the less perfect, the simpler does the eye become. In a general way we may distinguish between eyes which can differentiate between light and dark only, and eyes which perceive more or less perfect images of objects. The former are those of the lowest animals which have barely light perception and perhaps orientation. The latter are those of the higher classes, especially the vertebrata. The eyes of this group are so arranged that they can perceive a number of impressions at the same time and independently of each other, or in other words, images perceived by such eyes are composed of a large number of single impressions arranged like mosaic-work. The finer the parts of this mosaic, the more detail is perceived. This arrangement has reached its highest development in the eye of man.

In this second group we may recognize three forms of eyes. The *composite eye* (see article on COMPARATIVE ANATOMY), that of insects and crustaceans, is a hemispherical body composed of a varying number of single eyes of which from 20 to many thousands have been counted in different insects. Covered by a common transparent membrane, the cornea, these eyes form little prismatic boxes with from four to six angles, which lie close to each other arranged like radii. Their walls are usually pigmented, and thus virtually a vertical ray only can enter each of them. Sometimes the inner end of these boxes is convex, forming something like a lens, sometimes a lens-like transparent body lies in front, or the cornea is thickened so as to act like a lens. Others have a crystal cone going from each box to the nerve fibre connected with it. Such eyes cannot change their focal power. A higher form of eye is found in the nautilus. It forms a small camera obscura with a narrow pupil through which the light is admitted. This eye is supplied with a retina covering the wall opposite the pupil, with no arrangements of adjustment. The highest form of the eye, as found in the vertebrata, is a camera obscura, with a collective lens, capable of different degrees of focal adjustment. In the lower vertebrates this adjustment is made by bringing the retina nearer to the lens, in the higher ones the refraction of the lens is changed by an apparatus of accommodation. The former eyes are particularly adapted for seeing near objects.

There is a close relation between the eye and the mode of life and habitat of its possessor. Animals living in the water, or being most active at dusk, have a large flat cornea and a large pupil which admit much light. Some have, even, a reflecting apparatus behind the retina. The mode of locomotion has something to do with the position of the eye. Thus in the vertebrates, arthropods and cephalopods the eyes are situated at the head, while in the sea star, for instance, they lie at the tip of each of the five rays, in the worms on their gills, etc.

Man and the higher animals have two eyes. Most insects and some crustaceans have two composite eyes and a number of single supernumerary ones. Spiders have eight, some worms four or more supernumerary eyes. Some mollusks have up to several hundred eyes which lie along their mantle.

The eyes of the vertebrates, cephalopods and some snails have an external muscular apparatus. Those of the crabs lie at the end of a movable stem.

The shape of the eyeball is more or less spherical with a difference in the radius of curvature of the cornea and sclerotic. No eye seems to be perfectly spherical. That of aquatic birds is flatter than that of birds living in the air. The fishes have the flattest eyes.

The tissues of which the eye is composed show interesting differences in different species. The cornea is thickest in mammals; in the bat it is even much thicker than the sclerotic. In the terrestrial animals the radius of the corneal curvature is smaller than that of the sclerotic, in the animals living in the water the reverse obtains. In the mammalia the sclerotic consists of dense connective tissue, in the remaining vertebrata cartilage and even bone is added to this. In a large number of fishes we find on the outer surface of the chorioid a layer of iridescent crystals, the so-called argentea, which acts as a light reflector. In other fishes a cellular or fibrous membrane is found near the inner surface of the chorioid, called tapetum. The mammals, also, have a tapetum, hence their shining eyes.

The osseous fishes have a voluminous separate vascular tissue, improperly called chorioideal gland, interposed between the outer and inner layers of the chorioid. In birds a fan-shaped membrane, containing bloodvessels and being pigmented, springs from the optic papilla and its neighborhood and reaches into the vitreous body almost or altogether to the lens, the pecten or fan. It is less developed in nocturnal birds. A similar rudimentary appendage is found, also, in the eyes of some lizards.

The ciliary body and muscle, so well developed in man, is less and less developed the lower the animal. In the fishes its function seems to be reduced to the support of the lens and the nutrition of the anterior parts of the vitreous body. The lower the animal and the less accommodative function, the more spherical is the lens. The more developed the apparatus of accommodation, the more lentil-shaped is this organ.

The optic nerves in the lower animals seem to be as a rule totally crossed in the chiasma. The retina in a general way is very similarly constructed in all vertebrates. While man and the higher animals have one fovea centralis only, a great many birds have two foveæ centrales. One seems to serve for monocular and the other for binocular vision.

Diseases of the Eye.— The eye is subject to a great many diseases, which may originate in the eye itself or be symptoms and consequences of some systemic disease. The lids, conjunctiva and cornea being in an exposed position are very apt to become injured and diseased by direct infection from the outside. Infection from within and attacking the inner coats of the eye at first is, also, observed frequently. Certain toxins circulating in the blood produce characteristic diseases in the eye, like the neuro-retinitis of Bright's disease and the retinitis in diabetes. Certain diseases of the eye can be brought in connection with its refractive condition, thus glaucoma is more frequently seen in farsighted, detachment of the retina in nearsighted eyes. Many internal eye diseases may be traced to uncorrected errors of refraction. Thus, perhaps, this plays a decided role in the production of cataract. Errors of refraction and unequal visual acuity cause the parallelism of the eyes to be lost, farsightedness leading to convergent and nearsightedness to divergent squint. Some eye diseases are due to poisons ingested; the best known examples of this are, perhaps, the amblyopia from the abuse of nicotine and alcohol and the optic neuritis due to lead poisoning. Systemic diseases, like syphilis, rheumatism, gout, tuberculosis, are apt to cause diseases of the uveal tract, especially iritis and chorioiditis or of the retina and optic nerve. Brain diseases may lead to inflammation or atrophy of the optic nerve and to paresis or paralysis of the external and internal ocular muscles. Diseases of the vascular system are apt to produce hemorrhages in the eye or plugging of the central retinal artery and vein. Diseases of the nose are apt to produce stoppage of the drainage apparatus of the tears.

Injuries to the eyeballs are very frequent and may cause very serious results, especially iridochorioiditis with shrinkage of the eyeball, and such eyes are particularly prone to affect the fellow-eye by sympathetic inflammation, an almost incurable disease.

The most frequent eye diseases are those of the conjunctiva and lids, as stated above. The very situation of the conjunctiva and its being moist and warm renders it especially liable to infection from without and favorable to the propagation of germs. Thus blennorrhœa neonatorum, gonorrhœa, diphtheria, trachoma, let alone the milder forms of conjunctivitis, are due to such extraneous infection, as are also ulcers of the cornea.

Any dimness in the transparent media of the eye must of necessity interfere with vision, thus scars on the cornea, cataract, opacities in the vitreous body, etc., render the eye nearly or totally useless.

The eye is, furthermore, not infrequently the site of malignant tumors, as epithelioma, sarcoma and glioma of the retina.

Unlike other organs the eye is very often subject to important congenital malformations and anomalies.

A. Alt, M. D.,

Eyebright, a common name for the plants of the genus *Euphrasia* (q.v.).

Ey'erman, John, American geologist: b. Easton, Pa., 15 Jan. 1867. He studied at Lafayette College, Harvard, and Princeton, 1889–95, and was instructor in blow-piping at Lafayette 1888–93, and lecturer on determinative mineralogy. He has been an associate editor of the 'American Geologist' since 1890, and is a member of many English and American scientific societies. He has published: 'Notes on Geology and Mineralogy' (1889); 'Mineralogy of Pennsylvania' (1891); 'Course in Determinative Mineralogy' (1892); 'Bibliography of North American Vertebrate Palæontology' (1889–93); 'The Genus Temnœyon' (1895); 'A Study of Genealogy' (1898); 'General Index to the Wills of Northampton County, 1752–1802' (1898); 'The Old Grave Yards of Northampton' (1899–1901).

Eylau, ī'low, or **Prussian Eylau,** Germany, town, on the Pasmar River and the lake of Arschen; 22 miles south of Königsberg. It was the scene of a battle fought 7–8 Feb. 1807, between the French under Napoleon (q.v.) on the one side and the allied Russians and Prussians on the other side. (See Ney.) The French force numbered about 70,000, of whom fully 18,000 were killed. The allied forces were about the same in number with a loss of more than 18,000. Pop. 3,546.

Eyma, Louis Xavier, loo-ē ksăv-ē-ā ī-mä, French writer: b. Saint Pierre, Martinique, West Indies, 16 Oct. 1816; d. Paris 29 March 1876. After a tour through the United States, he returned to France and published several works, of which the best known are: 'The Women of the New World' (1853); 'The Red Skins' (1854); 'The Black Skins' (1856); 'The American Republic' (1861); 'The Slave Hunt' (1866); and many novels.

Eyra, ī'rä, in Scandinavian mythology, the physician of gods. See Mythology.

Eyra, a species of cat (*Felis eyra*) native to the western hemisphere from Mexico to Paraguay. It is rufous or chestnut in color, entirely without the spots found on other cats, except the puma, of which it seems almost a miniature. It has white spots on the face, is about the size of the domestic cat, and has rounded ears. The pupil of the eye also is round. The body and head are slender, and the tail is unusually long and thick. The legs are shorter than those of the domestic cat. The eyra is easily tamed, but never seems, even in domestication, to relinquish its fondness for preying upon poultry. In the feral state it hunts small animals and birds for food.

Eyre, ār, **Edward John,** English explorer and colonial governor: b. Yorkshire 5 Aug. 1815; d. Tavistock, Devonshire, 21 Dec. 1901. He went to Australia in 1833; in 1839 discovered Lake Torrens, and in 1840 explored its eastern shores and the adjacent Flinders Range. He then commenced his perilous journey along the shores of the Great Australian Bight, and reached King George's Sound, in western Australia, a distance of 1,200 miles, with a single native boy, having left Adelaide more than a year before. In 1845 he published 'Discoveries in Central Australia.' After filling several governorships he was appointed governor of Jamaica in 1862. In 1865 he was confronted with a negro rebellion which he crushed with some severity, and was recalled. On his return to England John Stuart Mill and others took measures to have him tried for murder, but failed. In regard to this question Carlyle was one of his most strenuous defenders.

Eyre, Lake, a salt lake of South Australia, lying due north of Spencer Gulf, at an altitude of 79 feet, and with an area of 3,706 square miles. Except in the season of rains, this lake is generally a mere salt marsh, and has no apparent outlet. It was discovered in 1840 by Eyre.

Eyre-Todd, George, Scottish miscellaneous writer: b. Govan, Scotland, 2 June 1862. He was educated at Glasgow University. He has published: 'The Lady of Ranza' (1884); 'The Sage of Thebes' (1885); 'Ossian' in Canterbury Poets Series (1888); 'Sketch Book of the North' (1890); 'Byways of the Scottish Border' (1892); 'Scotland; Picturesque and Traditional' (1895); 'Vignettes of the North' (1895); 'Anne of Argyle' (1895); 'The Book of Glasgow Cathedral' (1898); 'Bohemian Papers' (1898); 'Byways of Scottish Story' (1900); 'Songs of Caledonia' (1900); 'The Glasgow Poets' (1902).

Eyria (ī'rĭ-a) **Peninsula,** on the south coast of South Australia, triangular in shape, its base being formed by the Gawler Range, while its sides are washed on the southeast by Spencer Gulf, and on the southwest by the Great Australian Bight. It constitutes a rich pastoral country.

Eyster, Nellie Blessing, American writer: b. Frederick, Md., 7 Dec. 1831. She was married to A. S. Eyster 1853. She has published: 'Sunny Hours' (1865); 'On the Wing' (1860); 'Robert Brent's Three Christmas Days'; 'Lionel Wintour's Diary' (1882); 'A Colonial Boy' (1895); 'The Bright Side of Chinese Life' (1901); 'Opportunity and I' (1901); etc.

Eyth, Eduard, ĕd'oo-ärd īt, German poet: b. Heilbronn, Würtemberg, 2 July 1809; d. New Ulm 28 April 1884. He was author of a volume of 'Poems' (1843); 'Pictures in Frames' (1856); and a version of the 'Odyssey.'

Eytinge, ĕt'tĭng, **Rose,** American actress: b. Philadelphia 21 Nov. 1838. She made her début as an amateur in Brooklyn, N. Y., 1852, and the following year played through the West in a stock company. She has created many parts, including Rose Michel, Amande Chandoce in 'Led Astray,' and Felicia in the play of that name, but has been especially successful in her playing of Shakespearean roles, notably Cleopatra, Lady Macbeth, and Hermione (in the 'Winter's Tale'). She has written: 'It Happened This Way,' a novel; 'Golden Chains,' a play; and has dramatized Browning's 'Colombe's Birthday,' and Dickens' 'Dombey and Son'; 'David Copperfield'; 'Oliver Twist'; 'Tale of Two Cities,' and other works.

Eze'kiel, one of the greater Hebrew prophets. To him is attributed one of the larger prophetic books of the Old Testament, the visions and utterances which it contains being expressly attributed, in the work itself, to Ezekiel. He was the son of Buzi, a priest, and was carried captive, in the time of Jehoiachin, 595 B.C., about 11 years before the destruction of Jerusalem under Zedekiah. His prophecies are mostly in chronological order, those excepted which are launched against foreign nations. There is no direct quotation from Ezekiel in the New Testament, but there are a few allusions to his utterances, especially in the Book of Revelations, which, in the concluding portion, distinctly looks back to the temple arrangements prophesied in the last chapter of Ezekiel. The genuineness and authenticity of the prophecies of Ezekiel have not been seriously impugned either in the Jewish or Christian Church, and nearly universal suffrage has been given in favor of their canonicity.

Ezekiel, Book of, a series of prophecies, intended to warn and encourage the Hebrews during their captivity at Babylon in the 7th century B.C. The central point of the prophet's message is the destruction of Jerusalem, and his object is to call the people to repentance, to warn them against trusting in the help of Egypt (Ezek. xvii. 15-17), as a deliverance from the Babylonian yoke, and to assure them that the downfall of their city and temple was inevitable. At the same time, a future restoration is promised, and messages of consolation are mingled with denunciation and menace.

The whole book may be divided into nine main sections, as follows:

1. Ezekiel's call to the prophetic office.

2. The fulfilment of the commission symbolically outlined. Particular predictions of Jerusalem's destruction form the ground work of this vivid symbolism (Ezek. iii. 16.-vii.).

3. In a series of visions is revealed to the prophet the rejection of the people, because of their idolatrous worship. In these tableaux the temple is seen polluted by the worship of Adonis. But the denunciation of idolatrous priests and people is followed by promises of prosperity under a purer worship (Ezek. viii-xi.).

4. The sins, errors and prejudices of his contemporaries are rebuked in detail by the prophet (Ezek. xii.-xix.).

5. The especial and particular nature of the judgment, and the guilt that caused it, are unfolded in a series of thrilling denunciations, delivered about a twelvemonth later. The prophet announces that the judgment of God is drawing very near (Ezek. xx.-xxiii.).

6. He explains the significance of the now no longer impending, but actually commencing judgment. Jerusalem is being besieged, and the day when the siege began is announced to the captives. The city's complete overthrow is predicted (Ezek. xxiv.).

7. God's judgment against seven heathen nations is threatened (Ammon, xxv. 1-17; Moab, 8-11; Edom, 12-14; the Philistines, 15-17; Tyre, xxvi.-xxviii., 19; Sidon, 20-24; Egypt, xxix.-xxxii.).

8. A prophetic representation of the triumph of Israel and of the Kingdom of God on earth (Ezek. xxxiii.-xxxix.).

9. A symbolic representation, in whose glowing imagery the Messianic reign, and the establishment of God's Kingdom in power and prosperity are revealed (Ezek. xl.-xlviii.). Consult: 'Encyclopedia Biblica' (1903); also Cornill, 'Der Prophet Ezechiel Geschildert.'

Ezekiel, Moses Jacob, American sculptor: b. Richmond, Va., 28 Oct. 1844. He was graduated at the Virginia Military Institute 1866, having served in the Confederate army during the last year of his course. He studied art in Richmond and Cincinnati 1866-70, and Berlin, Germany, 1870-4, where he was the first foreigner to win the Michael Beer prize (1873). While there he studied under Prof. Albert Wolf, and was admitted to the Berlin Society of Artists on the merits of his colossal bust of Washington, now in Cincinnati. Later he went to Rome, Italy, where he has chiefly resided save for frequent visits to America. He has exhibited in the chief American and European expositions. Large and small, including statues, portrait-busts, ideal groups, and relievos. His works number several hundred of which the best known are: 'Cain, or the Offering Rejected,' an early ideal bust that showed considerable dramatic talent; 'Schiller and Goethe,' Berlin (1870); 'Religious Liberty,' Fairmount Park, Philadelphia (1874-6); bas-relief portraits of Farragut (1872), and Robert E. Lee (1873); 12 marble statues of artists for the Corcoran Art Museum, Washington (1880-2); marble busts of Beethoven (1884), and of Cardinal Hohenlohe (1888); bronze statue of Columbus in the Columbian Memorial building, Chicago, Ill.; statue of Mrs. Andrew D. White for Cornell University; bust of Lord Sherbrooke for Westminster Abbey; the fountain of Neptune for the town of Neptune, Italy, etc. In June 1903 the sculptor presented a bronze monument, 'Virginia Mourning Her Dead,' to the Virginia Military Institute.

Ez'ra, Jewish scribe and priest. Under his guidance the second expedition of the Jews set out from Babylon to Palestine under the reign of Artaxerxes I., about 458 B.C. The important services rendered by Ezra to his countrymen on that occasion, and also in arranging, and in some measure, it is believed, settling the canon of Scripture, are specially acknowledged by the Jews, and he has even been regarded as the second founder of the nation. Josephus states that he died in Jerusalem, and was buried there with great pomp; others assert that he returned to Babylon, and died there at the age of 120 years.

Ezra, The Book of, an Old Testament book, arranged in the English Bible between 2 Chronicles and Nehemiah. In the Thirty Nine Articles it is styled 'The First Book of Esdras.' The name Ezra, though commonly held to denote that he was the author of the book, however signifies no more than that the doings of Ezra are the main theme of the book, which is certainly the case. The period which the book spans is about 80 years, namely, from the first of Cyrus, 536 B.C., to the eighth of Artaxerxes Longimanus, 456 B.C.; the reigns embraced are those of Cyrus, Cambyses, Smerdis, Darius Hystaspis, Xerxes, and part of that of Artaxerxes. Both Jews and Christians consider the work part of the Scripture canon. It is written partly in Hebrew and partly in Chaldee, a fact which has led some to conclude that it is the work of different hands.

Ezra Church (Atlanta), **Battle of.** On 20 July 1864 the Confederate army under Gen. Hood was defeated at Peach Tree Creek, and driven into the inner defenses of Atlanta. On the 22d Hood attacked the Army of the Tennessee, and was again defeated, and Gen. Sherman began the investment of Atlanta. He began to force Hood from Atlanta by moving upon his communciations leading south from the city. The Army of the Tennessee was transferred from the extreme left of the investing line to the right, near Ezra Church, and Hood took measures to check its further extension and drive it back. On the night of the 27th he marched out of Atlanta with the greater part of his force, and on the 28th Gen. J. C. Brown's division was ordered to attack Logan's corps, then advancing on the right, and drive it back to and beyond Ezra Church. Brown drove in Logan's skirmishers, followed them 500 to 600 yards, and struck Logan's right, carried it at some points, but was quickly repulsed with great slaughter. He made a second attempt with no success and fell back. He had lost 694 killed and wounded and 113 missing. During Brown's attack four regiments from Dodge's and Blair's corps extended Logan's right, and took part in the action. Clayton's division attacked on Brown's right, but not until after Brown's first repulse, and by a misunderstanding his three brigades made isolated attacks upon Harrow's division, all of which were repulsed with great loss, some of the regiments losing 50 per cent. Walthall had led out his division while Brown and Clayton were engaged, and at 2 P.M., after they had been withdrawn, he was ordered to attack over the ground of Brown's fight. Walthall made several persistent efforts, but failed, although some parts of his force got within 50 yards of Logan's line. After more than an hour's severe fighting, in which he reports the loss of 152 officers and nearly 1,000 men, he fell back. At night Hood withdrew his troops to the works around Atlanta. The Federals in this battle numbered about 13,000 men; the Confederates about 18,000. The Union loss was 559 killed and wounded, 73 missing. The aggregate Confederate losses were apparently about 2,636 killed and wounded, and 200 missing. The estimates of Gens. Sherman, Howard, and Logan that the Confederate loss was from 5,000 to 7,000 are excessive. Consult: 'Official Records,' Vol. XXXVIII.; Cox, 'Atlanta'; Sherman, 'Personal Memoirs,' Vol. II.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. CARMAN.

F

F the sixth letter of the English and Latin alphabets and all alphabets derived from the Latin. The character F, though it does not appear in the Greek alphabet of the classic period, had a place in the earlier Greek alphabet, and is believed to have there represented the sound of *v* or of *w*. It is called by Greek grammarians, digamma or double-gamma, being formed of two gammas (g hard, Γ) written one above the other (F). From the Greek it came into Latin and, finally, was used to express the sound which it has for us. That the sound of F in Latin was the same as in English, we know from what Quintilian says of the mode of uttering it. The Greek letter Φ (phi) represented in Latin and English by *ph*, appears to have been very different in sound from the F of the Latins; and that in the pronunciation of F Greeks found great difficulty is known on the authority of Cicero; their difficulty was like that which people of other speech than ours find in pronouncing th in then, this, and in thin, think. A like difficulty in pronunciation of the F of Latin must have presented itself to the inhabitants of the Spanish peninsula, if not in the time of Roman domination, then after; else the initial F of words from the Latin would not have been so generally changed by them into a mere breathing, represented by the letter h. Examples: Lat. *faba* (bean), Span. *haba; fabulari* (to talk), *hablar; facere* (to make), *hacer.* In other languages, whether derived from one another or springing independently from a common original stem, as German, Anglo-Saxon, Greek, Latin, Celtic, etc., we see a different interchange as between F and P: thus to the English word fish answers the Latin *pisc* (*piscis*); to Eng. fire the Gr. *pyr*; to Eng. plow the Ger. *pflug.* In the local dialect of the English county of Somerset, F usually becomes V: fair becomes vair, friar vrier, five vive. As the Latin alphabet had but one character, V, to represent both the vowel U and the consonant V (or W) the Emperor Claudius ordered that in public inscriptions and state documents this consonant V should be represented by the F inverted, Ⅎ, and hence in monuments of that reign we find AMPLIAℲIT, TERMINAℲIT, OCTAℲIA, etc., for Ampliavit, Terminavit, Octavia, etc.

F. F. V.'s (First Family of Virginias), a jocular term applied in the North, before and during the war, to the Southern aristocracy in general.

Fa, fä, the name given by Guido to the fourth note of the natural diatonic scale of C, that is, the subdominant. In the major scale of C this tone is F.

Fabbri, fäb'rē, **Cora Randall,** American poet: b. New York 1871; d. there 1892. She was of Italian descent. A volume of her 'Lyrics' appeared but a few days before her death.

Fabens, Joseph Warren, American miscellaneous writer: b. Salem, Mass., 1821; d. 1875. Among his works are: 'The Camel Hunt,' a narrative of personal adventure; 'Facts about Santo Domingo'; and 'The Last Cigar,' a book of poems.

Faber, Frederick William, D.D., English theologian and hymn writer: b. Calverley, Yorkshire, 28 June 1814; d. Brompton, London, 26 Sept. 1863. He was a nephew of G. S. Faber (q.v.). He was educated at Balliol College, Oxford, where he came under the influence of John Henry Newman (q.v.), whom in 1845 he followed into the Roman Catholic Church. On becoming a Roman Catholic he founded a small community called Brothers of the Will of God, who three years later joined the oratory of St. Philip Neri. He afterward established a branch of this oratory at Brompton, with which he was connected till his death. His prose writings are numerous, but it is by his beautiful hymns that he is best known. Of these: 'Pilgrims of the Night,' and 'The Land Beyond the Sea,' are the most noted. See 'Life and Letters,' edited by Bowden (1869).

Faber, George Stanley, English theologian: b. Calverley, near Bradford, Yorkshire, 25 Oct. 1773; d. near Durham 27 Jan. 1854. Having been Bampton lecturer in 1801, he shortly after published his lectures under the title of 'Horæ Mosaicæ.' From the first he adopted evangelical views, and soon began to aid them by his pen, particularly by 'The Doctrine of Regeneration in the Case of Infant Baptism.' He was vicar successively of Stockton-upon-Tees, Redmanshall, and Longnewton, holding the last appointment 21 years, when he resigned it to become master of Sherburn Hospital. His principal writings, in addition to those already mentioned, are: 'A Dissertation on the Prophecies,' the most popular of all his works, having in 1818, only four years from its first appearance, reached a fifth edition; and the 'Difficulties of Romanism,' of which a third edition appeared in 1853.

Faber, Johann Lothar, German manufacturer: b. Stein, near Nuremberg, 12 June 1817; d. 1896. In 1760 he founded in his native town a manufactory of lead pencils, with only 20 hands employed. He made so many improvements in the manufacture that his factory gradually became the centre of that particular industry, and absorbed the trade of Germany and Austria. Particularly successful and profitable was the making of pencils of different grades, while his business capacity in distributing his goods did much to promote their popularity. He opened branches in great cities of Europe and the United States. In his factory at Noisy-le-Sec near Paris are employed more than a thousand operatives, and the Faber pencils are considered the best in the market.

Fabian, fā'bi-an, belonging or relating to the famous Roman family, or clan, the Fabian, used especially in the military phrase Fabian tactics, to denote tactics the chief point of which is to weary and exhaust the enemy. By such measures Quintus Fabius Maximus greatly harassed Hannibal in the Second Punic war.

Fabian Society, an English socialistic organization, having its headquarters in London, and with affiliated branches in most of the principal cities and towns of Great Britain and Ireland. The society includes in its ranks some very prominent writers on social economy, including Sidney Webb, and publishes 'Fabian Essays,' and 'Fabian Tracts.' In 1888 they began to hold public meetings. Above 700 lectures have been given in one year by members of the society. The Fabians aim to bring about the "emancipation of land and industrial capital from individual and class ownership and the vesting of them in the community for the general benefit"; "the extinction of rent"; and "the transfer to the community of the administration of such industrial capital as can be conveniently managed socially." They also advocate female suffrage. There is a society of the same name in the United States, which issues a periodical called the 'American Fabian.'

Fabié, François Joseph, frän-swä zhō-zef fä-byā, French poet: b. Durenque, France, 3 Nov. 1846. He filled important chairs in different colleges, attaining distinction as the author of 'The Poetry of the Foolish Ones' (1879); 'The Belfry'; etc., and by 'Roupeyrac's Mill,' a rustic drama, and other plays.

Fabii, fā'bi-ī, **Arch of the,** a commemorative arch in ancient Rome at the entrance of the Sacred Way (Via Sacra) to the Forum Romanum. It was constructed about 120 B.C. by Quintus Fabius Maximus Allobrogicus in celebration of his victories over the Allobroges and Arverni. Its material was the calcareous Italian rock called travertin, and its design simple. Some few of the travertin blocks were excavated in 1882 not far from the site of the arch.

Fabius, fā'bi-us, the name of one of the oldest and most famous families of Rome, every member of which was massacred at Cremera 478 B.C., except QUINTUS FABIUS VIBULANUS, who became one of the decemvirate. Among the most noted of the family in later times are: FABIUS AMBUSTUS, dictator, 350 B.C.; FABIUS RULLIANUS, to whose name MAXIMUS was added, twice dictator, conqueror of the Samnites and Etruscans, 323–280 B.C.; FABIUS GURGES, son of the preceding, consul of Rome; FABIUS PICTOR, the first writer of Roman history, 3d century B.C.; FABIUS MAXIMUS VERRUCOSUS, considered the greatest of his family, surnamed "Cunctator," "the Delayer" (see FABIAN), from his system of warfare. Died 203 B.C.; FABIUS MAXIMUS QUINTUS, son and next in office to the preceding, afterward consul; FABIUS MAXIMUS ÆMILIANUS, distinguished in the war of Persia and in Spain, consul 147 B.C.; FABIUS MAXIMUS SERVILIANUS, pro-consul for Spain, censor 126 B.C.; FABIUS MAXIMUS ALLOBROGICUS, consul 122 B.C.

Fable (Lat. *fabula*, a narrative, especially a fictitious one), in literature, a term applied originally to every imaginative tale, but confined in modern use to short stories, either in prose or verse, which are meant to inculcate a moral lesson in a pleasant garb. Imaginary persons, animals, and inanimate objects are introduced as the actors and speakers. The fables consist properly of two parts — the symbolical representation, and the application, or the instruction intended to be deduced from it, which latter is called the moral of the tale, and is indispensable to it.

Herder divides fables into (1) Theoretic, intended to form the understanding; thus a phenomenon of nature, as illustrative of the laws of the universe, is used to exercise the understanding. (2) Moral, which contain rules for the regulation of the will. We do not learn morality from the brutes, but view the great family of nature, and observe that she has connected the happiness of all living creatures with the unchangeable, eternal law of effort, and take example from the observance of this law by the lower orders of creation. (3) Fables of fate or destiny. It cannot always be made evident how one thing follows as a necessary consequence from another; here then comes in play that connection of events which we call fate, or chance, and which shows that things follow, at least after, if not from one another, by an order from above. Thus the eagle carries with her plunder a coal from the altar, which sets fire to her nest, and thus her unfledged brood becomes the prey of animals which she has already robbed of their young.

The oldest fables are supposed to be the Oriental; among these the Indian fables of Pilpay or Bidpai, and the fables of the Arabian Lokman, are celebrated. Æsop is well known among the Greeks, and was imitated by Phædrus among the Latin writers. Bodmer has published German fables of the time of the Minnesingers. The first known German fabulist is Stricker, who belongs to the first half of the 13th century, but the famous mediæval beast-epic of 'Reinecke Fuchs' (see REYNARD THE FOX) has a much more remote origin. Boner, who lived at the close of the 14th century, shows in his 'Edelstein' the true spirit of fable. Burkard Waldis may be mentioned in the 16th century. The most successful of German fable writers is undoubtedly Lessing. In the 17th century Gay among the English, and La Fontaine among the French, were distinguished. The writer last named made fable the vehicle of wit, and carried it to its highest stage of perfection. Among the most interesting modern productions in this department of literature the fables of the Russian, Ivan Kriloff, deserve special mention. See ALLEGORY; MYTH; PROVERB.

Fabliaux, fä-bli-ō (Fr. from the Lat. *fabula*, a narrative, particularly a fictitious narrative), in French literature, the short metrical tales of the Trouvères (q.v.), belonging for the most part in the 12th and 13th centuries. These productions were intended merely for recitation, not for singing, had as their principal subjects the current gossip and news of the day, and were epigrammatic and ironical in style.

Fabre, Amant Joseph, ä-mäṅ zhō-zef fäbr, a French author: b. Rodez, France, 10 Dec. 1842 (or 1843). A drama, 'Joan of Arc' (1890), made his name most widely known; his other works being largely represented by such books as: 'A Course in Philosophy' (1870); 'Washington, the Liberator of America' (1882).

Fabre, Ferdinand, fār-dē-näṅ, French novelist: b. Bédarieux, France, 1830; d. Paris 11 Feb. 1898. He published: 'Ivy Leaves,' poems (1853); then the novels: 'The Courbezons' (1861); 'Julien Savignac' (1863); 'My Uncle Célestin' (1881); 'King Ramiro' (1884); and 'Mr. John' (1886). The remarkable novel, 'Abbé Tigrane' (1873), first won him great distinction; 'Lucifer' (1884); portraying the struggle among the clergy between Gallicanism and Ultramontanism, is doubtless his greatest work. Among his shorter stories are: 'The Abbé Riotelet' (1891); 'Norine' (1890); 'Germany' (1891), etc. 'Ma Vocation' (1889) is a volume of leaves from his student diary.

Fabre, François Xavier Pascal, fräṅ-swä zäv-yā päs-cäl, French painter: b. Montpellier 1 April 1766; d. there 16 March 1837. He was a pupil of David, and produced in 1787 a painting representing the 'Execution of the Children of Zedekiah by order of Nebuchadnezzar,' for which he received the great prize of the academy, and was sent as a pensionary to Rome. He was believed to have been secretly married to the countess of Albany, who on her death in 1824 made him her sole heir, and bequeathed to him valuable MSS. which had been left to her by Alfieri. Fabre gave them to the city of Florence.

Fabre, Jean Raymond Auguste, zhŏṅ rā-mōṅ ōgüst, French poet, brother of Ferdinand Fabre (q.v.): b. Jaujac, France, 24 June 1792; d. Paris 23 Oct. 1839. He was prominent in journalism and wrote: 'Caledonia, or the Patriotic War' (1823); 'Histoire du Siège de Missolonghi' (1827); 'La révolution de 1830' (1833).

Fabre D'Eglantine, Philippe François Nazaire, fē-lēp fräṅ-swä nä-zār fäbr dā-glōṅ-tēn, French dramatic poet: b. Carcassonne 28 Dec. 1755; d. Paris 5 April 1794. Having gained the prize of the Eglantine in the Floreal games at Toulouse, he assumed the name of that flower as a surname. He now wrote several theatrical pieces, of which however only two, 'L'Intrigue épistolaire' and the 'Philinte de Molière,' were successful. The latter is still considered one of the best character-pieces of the modern French stage. He engaged with ardor in the Revolution, acting with Danton, Lacroix, and Camille Desmoulins. As deputy from Paris to the National Convention, he at first supported moderate principles, but afterward voted for the death of Louis XVI. without appeal, and was chosen a member of the committee of public safety. He afterward became suspected by the Jacobins, and being condemned to death was executed along with his colleague Danton (q.v.).

Fabretti, Raffaele, rä-fä-el'ā fä-bret'tē, Italian antiquarian: b. Urbino 1619; d. Rome 7 Jan. 1700. He was made papal treasurer by Alexander VII., and finally superintendent of the archives in the castle of San Angelo, which office he held till his death. Among his writings may be mentioned: 'De Aquæductibus veteris Romæ'; 'De Columna Trajani'; and 'Inscriptionum Antiquarum Explicatio,' in the last of which much light is thrown on the discoveries made by himself in the Catacombs.

Fabriano, Gentile da, jen-tē'lā dä fä-brē-ä'nō, Italian painter: b. Fabriano about 1370; d. Rome about 1450. His earliest work was perhaps the decoration of a chapel for Pandolfo Malatesta at Brescia. In 1423 he painted one of his best extant pictures, an 'Adoration of the Kings,' for the church of the Holy Trinity in Florence. To the same period belongs a Madonna with Saints (now in the Berlin Museum). A picture of the naval engagement between the fleet of Venice and that of the Emperor Barbarossa, which Fabriano painted for the Venetian senate, so pleased them that they conferred on him the dignity of a patrician and a pension of a ducat *per diem* for life. Fabriano next worked at Orvieto, but was called thence by Pope Martin V., who employed him in adorning the church of St. John Lateran with frescoes from the life of John the Baptist. Fabriano's pictures indicate a cheerful and joyous nature. He had a childlike love of splendor and rich ornamentation, but his coloring is never extravagant or meretricious.

Fabriano, Italy, city 20 miles northeast of Perugia. It is in the midst of mountain scenery, and in a fruit-growing region. This is the native place of the artist, Gentile da Fabriano (q.v.), a large number of whose paintings are preserved here in churches and in the city hall. Paper, parchment, gunpowder, glue, and felt-cloth are the chief manufactures. The paper and parchment factories were established in 1564. Pop. of the commune 21,000.

Fabricius, Hieronymus, hī-ĕr-ŏn'i-mus fā-brish'i-us (Ital. Fabrizio, Girolamo), Italian physician: b. Aquapendente 1537; d. Padua 23 May 1617. He studied at Padua under the celebrated Fallopius, whom he afterward succeeded in the anatomical chair, and had Harvey, the discoverer of the circulation of the blood, for a pupil. Harvey acknowledged that the discovery of the valves in the veins made by his master put him on the way of his discovery. During the lifetime of Fabricius his merit was fully recognized by the public and the state. His works were collected and published by Bohnius (1687).

Fabricius, Johann Albrecht, yō'hän äl'-breнt fä-brēt'se-ōs, German scholar: b. Leipsic 11 Nov. 1688; d. Hamburg 30 April 1736. He was versed in almost every department of human knowledge, particularly in philology and ancient literature, and understood the art of using these stores of erudition to the greatest advantage. He was professor of rhetoric and moral philosophy in the gymnasium at Hamburg. He published a 'Bibliotheca Græca' (1705–28); 'Bibliotheca Latina' (1697); 'Bibliotheca mediæ et infimæ Ætatis' (1734); 'Bibliotheca Ecclesiastica'; 'Bibliotheca Antiquaria' (1713).

Fabricius, Johann Christian, Danish entomologist: b. Tundern in the duchy of Schleswig 7 Jan. 1743; d. Kiel 3 March 1808. He pursued his studies at Leyden, Edinburgh, and Freiburg, in Saxony, and under Linnæus at Upsal. Few scholars of that great man profited more by his instructions. His works upon entomology show the principles, the method, and even the forms of expression, peculiar to Linnæus, applied to the development of a new, happy, and fruitful train of ideas. From his intercourse with him he derived his first notions of his system of arranging insects according to the organs of the mouth; and he endeavored to persuade Linnæus to make use of it in the new edition of his 'Systema Naturæ.' Fabricius obtained the professorship of natural history in the University of Kiel, and in 1775 appeared his 'System of Entomology,' which gave to this science an entirely new form. Two years afterward he developed in a second work the characters of the classes and orders, and demonstrated in the *prolegomena* the advantages of his method. In 1778 he published his 'Philosophia Entomologica,' written upon the plan of the well-known 'Philosophia Botanica.' From this time till his death he was constantly occupied in extending his system, and in publishing it, under various forms, in works of different titles. He was appointed counselor to the king of Denmark, and professor of political and rural economy.

Fabricius, Gaius Luscinus, kā'yus fā-brish'us lū-sī'nus, Roman general: d. after 275 B.C. He was twice consul, and gained several victories over the Samnites and Lucanians and was famed for his integrity and contempt of riches. This was shown on the occasion of his embassy to Pyrrhus in 280 B.C., when he firmly withstood all the attempts of Pyrrhus to allure him into his service. When consul, he discovered to Pyrrhus a plot formed to poison him by his physician; and in gratitude Pyrrhus released the Roman prisoners without ransom. Fabricius was afterward censor, and endeavored to check the growing passion for luxury. He lived a simple life and died poor.

Fabrics, Names of. The names given to most fabrics are derived from cities, towns, and persons. Damask is from Damascus; satins from Zay in China; calico from Calicut, India; muslin from Mosul; drugget is from Drogheda, Ireland; cambric from Cambral; taffeta from a street in Bagdad; gauze from Caza; dimity from Damietta; jeans from Jean; duck from Torque in Normandy; serge from Xerga, a Spanish name for a peculiar woolen blanket; velvet from the Italian *vellute;* chintz from the Indian *chott;* blanket is called after Thomas Blanket, a famous clothier who lived in England in 1340.

Fabroni, or **Fabbroni,** fä-brō'nē, **Giovanni Valentino Mathias,** Italian scientist: b. Florence 13 Feb. 1752; d. Pisa 17 Dec. 1822. He left behind him a considerable number of valuable memoirs and treatises on matters relating to chemistry, agriculture, physiology, etc., of which the best known are 'Provvedimenti Annonarj'; his 'Discourses on National Prosperity'; on 'The Equilibrium of Commerce, and the Establishment of Custom-houses'; on the 'Effects of the Free Traffic in Raw Material'; on 'Rewards for the Encouragement of Trade'; on the 'Chemical Action of Metals'; on the 'Value and Reciprocal Proportion of Coins'; on the 'Scales and Steelyards of the Chinese'; on the 'Palaces of Spain'; and on the 'Ancient Hebrew People.'

Façade, fa-sad' (Fr. "the front of a building"), the face or front of any building, particularly its principal face or faces; generally used of a building of magnitude or importance. A back elevation is termed a rear façade. See ARCHITECTURE.

Facciolati, or **Facciolato, Jacopo,** yä'kō-pō fä-chō-lä'tē or -tō, Italian philologist: b. Toregia, near Padua, 4 Jan. 1682; d. Padua 26 Aug. 1769. He devoted the greatest attention to reviving the study of ancient literature; and, accordingly, undertook a new edition of a dictionary in seven languages, which was called the 'Calepin,' from the name of its author, the monk Ambrosius Calepinus. His pupil, Forcellini, assisted him, and the work was completed between 1715 and 1719. He now, in company with his industrious disciple, conceived the idea of a Latin lexicon, in which every word, with all its significations, should be contained and illustrated by examples from the classical writers, after the manner of the dictionary of the Cruscan Academy. This immense undertaking occupied them both for nearly 40 years. Facciolati directed the work, which was almost entirely executed by Forcellini. He left many Latin discourses which are characterized by Ciceronian elegances of style, but differ from their model by a precise brevity.

Face. See SKULL.

Face Wheel, called also **Contrate Wheel** and **Crown Wheel,** a wheel which has cogs projecting from the periphery at right angles to the plane of motion; as, in watches, the wheel situated nearest the crown and driving the balance.

Facetiæ, fa-sē'shĭ-ē (Lat. "witticisms"), a collection of humorous sayings or tales, witticisms, and jests. Among the earliest such is that known as 'Asteia,' generally attributed to Hierocles. Latin collections were common in the later Middle Ages, the most notable being the 'Liber Facetiarum' (1470) of Poggio Bracciolini. See JEST-BOOK.

Fachan, or **Fatshan,** China, in the province of Kwang-Tung; on the Tu-Kiang, about 20 miles west by south of Canton. Its chief manufactures are iron and steel products, bamboo, and rattan articles, embroideries, and porcelain. Its trade is in manufactured articles and the agricultural products of the surrounding country. Pop. 500,000.

Fachingen-water (Ger. *Fachinger Wasser*), a mineral water, from a spring near Fachingen, a village of the governmental district of Wiesbaden, Prussia. It is reckoned among the strongest alkaline acidulous waters of Germany, being marked by a large content of carbonic acid and bicarbonate of soda. It is transparent, with a temperature of 10° C., and is used in cases of bronchial catarrh, catarrh of the stomach, gout, and other troubles.

Facial Angle, an anatomical term for the angle contained between two imaginary lines, one from the most prominent part of the forehead to the anterior extremity of the alveolar process of the upper jaw, opposite to the incisor teeth; the other from the external auditory foramen to the same point, serving to measure the elevation of the forehead. The angle is of great service in ethnology, but its magnitude is not an infallible criterion of the intellectual capacity of an individual. It is sometimes called Camper's angle, because the celebrated Dutch anatomist Camper was the first to draw attention to the importance of this method of skull measurement.

Facial Nerve. The seventh cranial nerve in the cerebro-spinal axis forms the chief motor nerve of the face. It originates in a group of ganglion cells lying in the floor of the fourth ventricle in the medulla. The fibres pass out through the temporal-bone lying by the side of the auditory nerve in the middle of the ear canal, and are finally distributed to the chief muscles of the face. Affections of this nerve cause partial or total loss of power of the muscles of the face. See Facial Paralysis.

Facial Nerve Paralysis, paralysis of the motor nerve which controls the muscles of the face. The paralysis may extend to one or both cheeks; but, in most cases, when the cause has been treated recovery follows.

Facial Neuralgia, a painful affection involving the chief sensory nerve of the face; the trigeminal or fifth nerve. This neuralgia may involve any of the branches and, because of their wide distribution over the shoulder, back of the neck, scalp, and face may be felt in a number of locations. Very frequently the pain is in the jaw and is due to diseased teeth, toothache being a form of neuralgia of this nerve.

The pain may radiate from over the orbit, constituting supra-orbital neuralgia, or it may be distributed over the back of the head, constituting occipital neuralgia. Occasionally neuralgia of the fifth nerve gives rise to typical attacks of sick-headache. A particular variety which is extremely severe, and is supposably due to disease of the sensory ganglia of the fifth nerve, is known as tic-douloureux. Characteristic features of neuralgias of the face are the sudden shooting, darting pains, usually one-sided, unaccompanied with other constitutional disturbances. The cause is most frequently exposure to cold. From riding on the tops of omnibuses, sitting by the open windows of railroad-cars, or by any open window with a draft blowing through, persons are very frequently affected. At times anæmia, gout, and infection from bad teeth occasion facial neuralgia.

Treatment will depend largely upon the exciting cause. Heat, gentle massage, simple diet, and free movements of the bowels are general measures to be carried out. Occasional surgical intervention is necessary to cure tic-douloureux. The medical treatment of neuralgias of the face is technical and involves the use of remedies that are dangerous in the hands of laymen.

Facial Paralysis, a partial or total loss of power in the muscles of the face. One side of the face alone is usually affected. Paralysis may result from any disease of or injury to the facial nerve, either inside of the skull proper, or in its external distribution. Paralysis of the face very frequently occurs in apoplexies. Here the disease results from a disturbance of the nerve in its intracranial portion. It also is occasioned by disease in the middle ear, but is most frequent following exposure to cold, during which the external branches are involved. This latter form is termed Bell's palsy (q.v.). The symptoms of facial paralysis may vary according to the number of branches of the nerve that may be involved. In a complete case the paralyzed side is flat and expressionless, the mouth is drawn toward the well side, making the well side look as though it were contorted and diseased. The patient is unable to whistle, and may not be able to talk very clearly. The tongue may be protruded toward the well side. There may be inability to close the eyelids. Sensation is not involved. When the patient eats he may not be able to move the tongue on the paralyzed side of the mouth, and he cannot fill out his cheeks on the flat side. The electrical reactions of the muscles at first may not be affected, but later what is known as the reaction of degeneration sets in. Most cases of facial paralysis due to peripheral trouble, as well as Bell's palsy, recover of themselves; others, due to hemiplegia or to inflammation of the middle ear or to fracture of the skull, recover less frequently.

Treatment is by means of tonics — iron, strychnine, arsenic, and electricity. In intractable cases surgical anastomosis with other motor nerves may prove of service.

Facial Spasm. See Tics.

Factor (Lat. "a maker"). (1) An agent or substitute, especially a steward or agent of an estate, appointed by a landowner to manage the estate, collect rents, let lands, etc.; also an agent employed by merchants to transact business for them in other places, as to buy and sell, to negotiate bills of exchange, etc. He differs from a broker in that he is entrusted with the possession and disposal of the goods, property, etc., and may buy and sell in his own name. See Agent. (2) In arithmetic any one of the integers the product of which is a given number. A prime factor is a factor which is also a prime number. (3) In algebra, any one of the quantities which, when multiplied, produce a given algebraic expression.

Factor of Safety. See Strength of Materials.

Factories and Factory Inspection. During the reign of Edward III., the making of woolen cloths became an industry, and some of the phases of the factory system began to appear. This industry was fostered by Edward, and at the suggestion of Queen Philippa he invited one John Kempe, a Flemish manufacturer of textiles, to come to England with his skilled workmen, and promised them protection and assistance. Accordingly by act of Parliament, the woolen manufacturers were first established in England, in the town of Kendal, manufacturing the cloth that was known as Kendal-green. Previous to the time of Edward III., English wool was largely in demand on the continent, and now, the better to protect this new industry, Edward forbade the export of wool under the penalty of death, and obliged his people to wear, as he himself wore, only the natural cloth. From this time on by legislation and protection, England took care of its woolen industries, until the time of Elizabeth, when free importation of wool was permitted, and some historians point to the fact that during her reign the manufacturers made most rapid progress; charity schools and poorhouses were established, which in after years were to form a strong factor in the factory system, and ultimately to improve factory conditions. About this time improvements had been made in the stocking loom, a great demand for yarns springing up, and new materials were sought. The cotton wool, a new material in weaving, which was to be the most important in the modern factory system, was given its impetus. The iron manufacture by the middle of the 18th century had almost come to a stand-still, owing to the destruction of the forest woods, which were used for coal. In 1756, making iron by the use of pit coal was successful, and the manufacture of iron again began to be one of the principal industries. By the middle of the 18th century the first factory, in the present sense of the word, was built by Lombe Brothers. It was a silk-mill, and the first in which the motive power was supplied from the outside, and machinery did the work heretofore supplied by human hands. The power used was a water wheel. This naturally set inventive minds to work with a view to supplying like mechanism to other grades, and many inventions sprang up, particularly for using the cotton wool. Arkwright came to the front with his water-frame, so-called, because water was the motive power. There began a rapid development in spinning machines, which were first applied to cotton, and in this industry we have the explanation how the earlier triumphs of the factory system were won. In the beginning of the 19th century, the modern factory system became established and the child-labor question arose. As the mills were first established by the streams, so that wheels might be moved by water power, it often happened that labor could not be had in the vicinity. Application was made to the almshouse for children who were indentured or bound out at a fixed rate, and for a certain length of time. Forced to work whether sick or well, often 16 hours a day, and given nothing for breakfast but water porridge, these children were visited with serious epidemics, and the attention of the public was thus aroused. In 1802 the first factory act for the "Preservation of the health and morals of apprentices in cotton mills" was introduced by Sir Edward Peel, one of the large manufacturers of that time. All mills employing 3 or more apprentices, or 20 other persons, were subject to this act. The most important clause was that which fixed 12 hours as a working day, and prohibited work altogether from 9 P.M. to 6 A.M.

In the earlier years of the factory in the United States, each home had its spindles and loom to fill the needs of its own members, the flax and cotton being grown, spun, and wove by the individual householder, or the slaves on the plantations. England frowned upon all manufactures in her colonies, and would allow no machinery or parts of machinery to be brought to this country, but could not fetter the brain, nor forbid the inventive genius, and Slatter and his associates, who coming to this country in the latter part of 1700, brought with them the knowledge which in 1803 built in Massachusetts the first cotton-mill in America. The first mill to take cotton in its crude state and pass it through the different processes to the woven cloth, was erected in Waltham, Mass., in 1813. The first type foundry was built in Philadelphia in 1794. The first glass-house was constructed in Pittsburg in 1796. Other factories followed in rapid succession between 1796 and 1810.

The first factory inspection law was adopted in England about the beginning of the 19th century, as a result of the agitation caused by epidemics among children and women in factories, but it was not until 1819 that the law was made effective. The abuses became so great that the government was at last compelled to interfere in the interests of humanity. This began by asserting the right of the state to control industrial establishments, where women and children were employed, but this necessarily involved the freedom of men in making contracts. The law was intended more particularly to meet the evils of the apprentice system, but it did not extend to factories, where children residing in the neighborhood were employed. From time to time this act has been amended, and the authority of government extended, so as to make it generally effective for the protection of all labor. It was thus in England that the value of factory inspection was first determined by experience. Subsequently it was introduced into this country. Massachusetts was the first American State to adopt a law of that character.

To-day there are factory laws in the United States based on the Massachusetts laws, for the examination and approval of plans of factories, apartment and tenement houses, also for proper fire-fighting, means of egress, and sanitary provisions; regulating the employment of labor of women and minors in manufacturing, mechanical and mercantile establishments and workshops; guarding of machinery; the construction of safety appliances of elevators; ventilation of factories and workshops; provision of water-closets for the use of each sex employed in factories and workshops, and various other sanitary regulations; uniform hours for meals for women and young persons; communication between the engineer's room and each room where machinery is run by steam; proper safeguards at hatchways, elevator openings and well-holes in public buildings, factories and mercantile establishments; competent watchmen and red lights in hotels; prohibiting during working hours the locking of any inside or outside door of any building where operatives are employed; weekly payment of wages; and sundry other matters; the granting of licenses to make, alter, repair, or finish coats, vests, trousers or wearing apparel of any description in a room or apartment in a tenement or dwelling house; the examination of engineers and firemen, and the inspection of boilers, granting of licenses, and steam power to be used. Women are protected by law from overwork by their employers and children are excluded from factories until of proper age, and Massachusetts has been from the first, and continues to be, in the advance in factory inspection, and under this system her industrial establishments have become models for all the other States. It is a marked illustration of what such a law accomplishes for a community.

International Association of Factory Inspection.— The International Association of Factory Inspection was organized at Philadelphia in 1886, and includes Canada, and the States of Massachusetts, New York, New Jersey, Pennsylvania, Rhode Island, Connecticut, Maine, Michigan, Ohio, Minnesota, Illinois, Wisconsin, Missouri, and Indiana. Each of these several States holds an annual convention of its inspectors, who meet to compare notes of their work for the year, and as their proceedings are made public, each State may know the advancement the other is making in its labor laws.

The inspection laws of Massachusetts are enforced by the inspection department, comprising 35 members, assigned to the duty of the examination and approval of plans for the construction of school, and other public buildings coming under the provisions of the law, relative to means of egress and to prevent the spread of fire; the proper heating and ventilating of school and other public buildings and examination of buildings reported to be unsafe to life or limb. Relative to the employment of children under the laws of the Commonwealth of Massachusetts, Inspector-in-Chief Rufus R. Wade says, in his last report: "During my service as chief of this department, I have seen the gradual rise and progress of legislation relative to the employment of child labor. The development of the labor question brought to the attention of successive legislatures, facts in relation to the employment of children, and whether from motives of humanity, or from other considerations, the legislatures have from 1874, when the so-called 10-hour law was enacted, down to the session of the present year, thrown the safeguard of law around the child-workers, and protected them from the evils and dangers to which they were exposed by the cupidity or thoughtlessness of others."

In 1876 an act was passed in Massachusetts prohibiting the employment of children under 10 years of age. In 1883 the limit was extended by providing that no child under 12 years of age should be employed during the hours in which the public schools were in session. Again in 1885 another change was made, which provided that no child under 12 years of age should be employed at any time during the day in which the public schools were in session. In 1888 these several statutes were repealed, and provisions were made that no child under 13 years of age should be employed at any time in any factory, workshop, or mercantile establishment, thereby raising the limit without any qualification to 13 years; the statute also providing that no such child should be employed except during the vacation of the public schools in the city or town where he resides, unless the person or corporation employing him, procured and kept on file a certificate and an employment ticket for such child as prescribed by law. Again in 1898 the limit was raised to 14 years, and providing that no child under 14 years of age can be employed at any time in a factory, workshop, or mercantile establishment, and no child under 16 years of age can be employed in a factory, workshop, or mercantile establishment unless the employer procures and keeps on file a certificate, and posts near the principal entrance a list of all such children employed. States that have adopted the factory inspection system have similar child labor laws, differing as to their age, to the age limit when they can be employed. In some kinds of manufacturing, especially in the textile- and cotton-mills, young children can be employed to advantage. The children enter the mills when very young and soon become experts in certain parts of the business, and by the time they become men and women are able to command very good wages. This custom is now practised to some extent by foreigners in mill districts, who make every attempt to get their children employed, not seeming to care as to age or education, and as soon as their children begin to earn good wages, the parents stop work and live upon what their children earn. The laws of the State of Massachusetts are very good in some respects as to child labor, but when a child lives in a town where there are no evening schools, and the child comes from a foreign country, and has attained the age of 14 years, the parents can procure a certificate for them, and they can be employed, not being able to read at sight and write legibly simple sentences in the English language. Evening schools are now maintained by law only in towns where there are 10,000 or more inhabitants. These children should be made to attend the public day school, but at the present time they cannot legally be compelled to attend school.

The Fifty-Eight-Hour Law.— In the State of Massachusetts children under 18 years and women cannot be legally employed more than 58 hours in a week in a factory, workshop, or mercantile establishment, and every employer must post in a conspicuous place the number of working hours each day of the week, the hours allowed for meals, the hours when starting and stopping work, and it becomes a part of the inspector's business to see that this is faithfully complied with. This has been the law of the State since 1894. Previous to that time, a week's work for children and women in factories and workshops was 60 hours a week, and still at an earlier time there was scarcely any limit to the hours of labor. From 1874 to 1894 10 hours a day, or 60 hours a week was the limit. In 1900 a law was enacted by the legislature prohibiting the employment of children under 18 and women over 58 hours per week in a mercantile establishment, and obliging the employer to post a notice stating the hours of work required of them for each day of the week, and the hours allowed for dinner or other meals. Before this date there was no limit to the hours required of a female after she was 18 years of age, and 60 hours a week was required of females under 18 years of age.

Employment of Illiterate Minors.— The definition of an illiterate minor in the Massachusetts laws is one who cannot read at sight and write simple sentences in the English language, no matter how well he can read or write in any foreign language. The law provides that every minor over 14 years of age, who resides in a city or town where there is an evening school maintained, and who cannot read at sight and write legibly simple sentences in the English language, must attend day or evening school, or he or she cannot be employed while the evening school is in session.

Pure Drinking Water to be Provided.— All manufacturing establishments in Massachusetts shall provide fresh and pure drinking water, to which their employees shall have access during working hours.

The Care and Custody of Elevators.— The carelessness of those who operate elevators, and who have the safety of human life in their care, seems to be the source of many accidents. In Massachusetts all elevators for the carrying of freight or passengers, running at a speed of more than 100 feet a minute, must be operated by competent persons not less than 18 years of age, and no other person shall operate, or have the care or charge of such elevator, and no elevator shall be operated by, or placed in charge of any person under 16 years of age, whatever less than 100 feet a minute may be its speed.

Sanitary Provisions in Factories and Workshops.— The laws of Massachusetts and other States that have factory inspection laws have the most rigid sanitary regulations, and are provided in the interest of comfort, decency, and health. These relate to factories, workshops, mercantile establishments, offices, school-houses, and public buildings. It is required that these buildings shall be kept free from all effluvia arising from drains and that they shall have a proper number of water-closets provided for persons of each sex. It is also provided that during working hours these buildings shall be ventilated, that the air may not become injurious to the health of the persons employed therein. It also provides that all dust from the grinding or polishing of metals be carried away through suction pipes.

The Inspection of Boilers and Engineers' Licenses.— The Massachusetts law as now enforced reads as follows: "It shall be unlawful for any person to have charge of, or to operate a steam-boiler or engine, except boilers and engines of locomotive motor-road vehicles, boilers in private residences, in apartment houses of less than five flats, boilers under the jurisdiction of the United States, boilers used for agricultural purposes exclusively, boilers of less than 8 horsepower, and boilers used for heating purposes, limiting the pressure to 15 pounds to the square inch, other than these boilers above excepted; the person in charge must hold a license granted after a thorough examination by the inspectors appointed for this duty, who are expert engineers."

The Sweatshop System.— With the introduction of the sweating system in the United States came a revolution in the clothing industry which has left in its wake destruction and poverty; for prior to the introduction of this system there was not, as a class, a better-paid people than those engaged in the ready-made clothing trade. Looking backward only a few years we have the recollection of a movement in sympathy with a people who were being driven from Russia and other European countries. The first duty upon arrival was to procure means to provide food and shelter for themselves and families, and, being without funds, the task became a very complicated one. The inducement to learn a good trade was freely offered them, provided they would work cheap enough to warrant a sufficient return for the knowledge bestowed upon them. The custom in vogue was that the apprentice should give from one to three months at very small pay, giving from 12 to 16 hours as a day's work. The profits to contractors employing this class of help was, of course, enormous. The immense amount of available labor, of this class, to a new method of employment which is called the task system, and to which the term "sweating" system was aptly applied. The sweating system, if conducted in workshops located in buildings devoted exclusively to manufacturing purposes, would never have obtained its present prominence in the public mind; but the competition between the employers of labor under this system resulted in a complete revision of conditions; cheaper shops were secured; large quantities of work per day were imposed upon the employed, until finally the tenement of the contractor was made to answer the double purpose of home and shop. The crowded condition of these tenements, hardly sufficiently large for the accommodation of the family, was increased by the addition of the help to be employed. All traces of home privacy were obliterated, sanitary conditions became unmentionable, filth and disease abounded, and the health of the public became endangered. When these conditions were made plain to the people, fear overcame them and appeals to the State legislature for the prevention of this system of manufacture were made. These appeals led to the enactment of laws tending to restrict the manufacture of clothing in tenement houses. The first law enacted, like most which tend to elevate the conditions of those who are obliged to labor for their living, emanated from the legislature of Massachusetts. This law provided that any house, room or place, used as a dwelling, and also used for the purpose of manufacturing, should within the meaning of the law, be deemed a workshop. The law defines a workshop as meaning any premises, room, or place wherein manual labor is exercised by way of trade, or for purposes of gain, but the exercise of such labor in a private house by the family, if a majority of the persons therein employed are members of such family, shall not constitute a workshop. The law also contained a provision which was intended to prevent the importation into the State of garments which had been made under unhealthful conditions, and this was enforced until similar laws were enacted in other States, particularly in the State of New York, from which the majority of this class of clothing was produced. The law also provides that any family desiring to do the work of making, repairing, or finishing any coats, vests, trousers, or wearing apparel of any description, in any room or apartment, in any tenement or dwelling house, shall first procure a license, approved by the chief of the inspection department. Every room or apartment in which any garments are made, shall be subject to the inspection and examination of the inspectors, for the purpose of ascertaining whether the rooms or apartments are clean and free from any contagious nature. If the inspector finds evidence of infectious disease present he shall report to the local board of health.

The laws of Massachusetts require that no building which is designed to be used above the second story as a factory, or workshop, or mercantile, or other establishment, and has accommodations for 10 or more above the second story, and no building more than two stories in height shall be erected until a copy of the plans thereof has been deposited with the inspectors. Such buildings shall not be erected without sufficient egress and other means of escape from fire, properly located and constructed. Such inspector may require that proper appliances shall be provided in the floors, walls, and partitions of such buildings to prevent the spread of fire.

Charles E. Burfitt,
State Factory Inspector, Boston.

Factory Acts. See Child-labor; Labor Legislation.

Factory Economics. From the primitive condition where each man must shift for himself, evolution leads to a state of society where the individual expends his energy upon some congenial occupation and exchanges his product for the diverse results of the work of others. The concentration of interest and skill on special trades enables the development of tools and machinery of a degree of complication which places them beyond the power of the workman to own or operate individually. Almost every form of constructive work is now carried on by groups of specialized workers, each proficient in but one task and requiring for the best results a large investment in buildings, machinery, and other equipments. Each man receives a daily wage depending remotely upon the momentary condition of trade in the product he assists to make, and generally reduced or cut off only after a protracted period of business stagnation. To successfully provide for a comparatively regular outlay for pay-roll, material, and factory expense from the irregular receipts from sales is the problem of factory management.

Expectation of Profit.—The promoter of a manufacturing enterprise must first demonstrate a prospective profit to the capital invested. Monopoly, as by patent, franchise, or arbitrary conditions; natural advantages of location, affording cheap power or raw materials, low cost of land with corresponding low rental or interest charge, convenient transportation facilities, a good labor market, proximity to place of principal sales, and superior design backed by persistent effort to keep the advantage, are all factors in the problem of expected profits. The cost of product is made up of the value of material and labor. In factory accounting this sum is known as the net or "prime" cost. In addition to this, factory work is done with the aid of a force of laborers, sweeps, stock handlers, crane men, power plant employees, pattern-makers, draftsmen, office men, and salaried officials whose work cannot generally be determined to be upon this or that particular "job," though quite as much part of the cost of product as is the direct labor. Equally undistributable are the general expense account, and the cost of marketing, made up of advertising, salesmen's salaries, and collection expenses. If the estimated selling price affords a probable margin of profit above the total cost made up of all these items, the enterprise has a chance of success, which may be increased by the ability of the sales department to raise prices, and of the constructing department to reduce costs.

Factory Construction and Equipment.—Essentials for economical production are abundance of daylight, preferably from overhead and the north side, ample space for unfinished work convenient to machines where it is handled, "routing" arranged so that as nearly as possible all articles are carried in one direction from the place of entrance successively to the proper machines and rooms for storage of finished product, and suitable transportation facilities, such as traveling cranes, trolley conveyors, and industrial railways. Tools and supplies are stored in central locations, cared for by attendants, and issued under restrictions which will prevent waste and loss. Machines must be selected of such dimensions and capacities that they may be usually worked to their maximum. Modern practice drives all machinery at maximum rates, in order to earn its cost before better tools are invented. With reference to the working force, comfortable, clean, and pleasant surroundings are of actual cash value to the management in increased quantity and quality of product. A sufficiency of unskilled labor must be supplied to save the time and steps of the skilled men. The most expensive item about the factory, generally speaking, is labor; which should be economized by labor-saving devices wherever possible, except where the cost of the daily operation of improvements is greater than the amount paid for labor that might be so saved.

Starting the Plant.—A new factory is merely an aggregation of men and machines, and until this condition is passed the financial results will be disappointing. The intangible something that puts the balance on the right side of the old factory's ledger comes with the better acquaintance of the various heads and their individual employees, the gradual elimination of weak points in the equipment, the construction and adaptation of "jigs" for quickly and conveniently handling work, and the gathering of records of past performances which measure the progress or backsliding of each repetition job. The books of the general office show the results of the transactions of the company with stockholders and others. The records of the cost department account for pay-roll and merchandise expenditures in such detail as to show accurately the cost of operating the machines, discover petty losses, suggest promising opportunities for cost reduction, and compare recent work with previous jobs or with the work of other factories.

Direct and Indirect Expense.—To this end distinctive order numbers or symbols are assigned to each piece or class of work, and accounts opened with each, to which labor and material are charged, thus giving "prime" or "direct" costs; to these amounts are added charges determined by arbitrarily fixed rules designed to indicate that proportion of the general operating expense fairly borne by each particular order, and known as "burden" charges. The burden rate may be laid out to cover the total of expense outside of material and direct labor; or preferably separated, the first addition covering only that portion belonging to factory operation, in which case the cost so far found is the manufacturing cost, and is a proper charge against an outsider bringing shop work of a familiar kind and taking it away when done. In most cases further expense is incurred for royalties, freight, and insurance on shipments to purchasers, and with large machinery, erecting expense; also for the shipping and billing force. The addition of this total in the form of a second burden charge gives the cost of the completed and delivered goods. Finally, there is the selling expense, which advances the total cost of product so that a very short profit may bridge the gap to the total income from sales.

Classification of Indirect Expense.— A fundamental principle is to charge direct to the order whatever can be determined to have been used thereon. The indistributable items will form some or all of the following accounts:

Manufacturing Expense, a general division comprising the following: *Rent,* or charges such as interest on bonds or fixed dividends on preferred stock representing the actual value of the property occupied; *Shop Salaries*, foremen's and clerks' wages; *General Labor*, all unskilled or skilled men not directly employed in manufacturing, such as helpers, watchmen, crane tenders and teamsters; *Supplies*, as oils, waste, files, paint, etc.; *Power, Heat and Light*, comprising fuel, water rent, power plant labor and supplies, belt renewals, pipe repairs and kindred items; *Defective Work*, expenses due to replacing incorrect, defective and spoiled work, which chance alone causes to fall on one job rather than another. *Repairs*, conveniently divided among the four heads, Buildings, Machinery, Small Tools, and General.

Administrative Expense.— Salaries, of draftsmen, office force and cost clerks; *Office Expense; General Expense*, not otherwise assigned; *Interest and Discount; Legal Expenses; Traveling.*

Selling Expense.— Commissions, and salaries; *Advertising; Traveling; Reclamation.* All these accounts should be defined in writing so that charges may be made consistently. Often further subdivisions are desirable; or heads different from those given, which pertain more particularly to machine construction. Each invoice when approved for entry is posted to the proper account, together with amounts paid for work and materials where such pertain to these accounts, and general totals are taken off at the end of each month.

Three Ways to Distribute Indirect Expense.— The problem is to determine the amount to add to the prime cost of each production order, so that the sum of all the amounts so added will approximate the total of the manufacturing expense accounts to date. The easiest, but generally the most inaccurate way is to add a percentage to the direct labor cost. A better way is to base the addition on the time taken to do the job. The best is a combination of the two.

To explain: Suppose wages actually paid for productive work — "direct" labor — amounts to $10,000, and manufacturing expense to $12,500. By adding to the cost of each order a sum equal to 125 per cent of wages paid for direct labor the problem is solved. But by this method, a job done in two hours by a 30-cent man on an expensive machine tool would appear to cost the same as if done in six hours by a 10-cent boy, ignoring the fact that the boy used the tool three times as long as the man, during which time the interest on first cost, depreciation, rent and heating expense went on at the usual rate, while the power used was probably no less, and the wear and tear perhaps more than with the more experienced man. The method is correct only for manufacturing operations done by men at equal wages on tools of equal value. By the second method, assuming that the $10,000 was paid to 180 men working 250 hours each, or 45,000 hours; the expense total of $12,500 being therefore equal to about 28 cents per hour, the job just instanced would be estimated to cost by the man $1.16, and by the boy $2.28. This method is correct where men earning various wages use tools all alike, but inaccurate where, as is usually the case, different employees use apparatus varying from a few hand tools to a $10,000 machine. The exact method is to divide the expense accounts into two classes, and apportion those which like light, heat, superintendence and clerk's wages belong equally to all the workmen, by a man-hour-rate found by the second method, and those which like power, repairs, rent and depreciation, etc., belong properly to the machines, by special tool-hour-rates based on careful study of the expense of operating each tool. Thus, suppose with the same hypothetical figures that $2,500 is found to be the total of the first class of expenses, or an hour-rate of 5½ cents for the 45,000 hours; while a large chucking machine carries as its monthly burden the value of space occupied at $30, interest and depreciation at 15 per cent on its cost of $2,000, making $25, 10 horse-power for its operation, costing $25, and other charges similarly determined to be $30, or a total of $110, distributed over a month averaging 150 hours running time, consequently at an hour rate of 73 cents. Rates being similarly determined for each machine or hand-work equipment, the cost of a one-hour job by a 30-cent man on this hypothetical chucking machine would be $30 + 73 + 5\frac{1}{2}$ cents, or $1.08½, while the same piece, if it could be made by a 10-cent boy in three hours on an engine-lathe with an hour-rate of 20 cents, would cost $30 + 60 + 16\frac{1}{2}$ cents, or $1.06½. The exact method here reveals that the expensive tool on this particular piece is saving nothing, and must show up better on other work or be arranged for use on more jobs. If run for the full shop time of 250 hours per month, its burden-rate would fall to 44 cents, and the supposed job would become profitable.

Convenient Simplification of Burden-charge.—In practice it is entirely satisfactory, after working out the man-hour and tool-hour rates, to combine and modify such as fall close together into two, three, or at most four class-rates; thus deciding that all work by hand on certain small machines shall carry Class A burden of, say, 10 cents per hour, another lot of larger tools Class B rate of, say 25 cents, and so on. This compromise gives good results, enabling the management to say definitely whether any particular job or class of product is paying for its real cost. Manufacturers using flat burden rates bid too low on work which, by reason of using their heaviest equipment, is unprofitable at the prices secured, and too high on work which employs mostly cheap labor and tools and would pay well at a lower figure. To determine truly the relative profits of different kinds of work it is advisable to apportion selling expense in a similar way, estimating the cost of selling each class and size of products and charging in the form of a percentage burden-rate on the gross cost of the goods.

Cost, Profit, and Selling Price.—Sub-totals of the cost of the month's completed work are credited on the general ledger, labor to "pay-roll," material to "merchandise," and burden to "distribution," while the corresponding charge is made to "manufacturing account." On the other side of the latter appears the total price received from or charged to customers for completed work. If the burden rates are modified, as is necessary from time to time to keep the distribution account approximately equal to the total expense account, the excess of the credit side of the "manufacturing account" shows the profit made by the sale of the product.

S. H. Bunnell,
Works Manager, Watertown Engine Company, Watertown, N. Y.

Faculties, Court of, an English ecclesiastical court, under the archbishop, which creates rights to pews, monuments, and particular places and modes of burial, and has also various powers in granting licenses of different descriptions, as a license to marry, a faculty to erect an organ in a parish church, or to remove bodies previously buried.

Faculty, in ecclesiastical law, a privilege or license granted to any person by favor, and not as a right to do any act which by law he may not do. In the Roman Catholic Church, permission granted by an ecclesiastical superior to a duly qualified subject to hear confessions. Such permission only extends to the district over which the superior has jurisdiction. Thus, faculties are granted by bishops to the priests in their dioceses, and by the heads of religious houses to such of their subjects as they judge qualified to hear the confessions of the community. In the United States, the term faculty indicates the body of persons who are entrusted with the government and instruction of a university or college as a whole, comprising the president, professors, and tutors. It is also used for the body of masters and professors of each of the several departments of instruction in a university; as, the law faculty, etc.

Fadeyev, Rostislav Andreievitch, Russian military writer: b. 1824; d. Odessa 12 Jan. 1884. He made more than one campaign in the Caucasus; achieving a reputation as a scientific soldier that commands respect for his 'Russian Military Power' (1868); 'My Opinions of the Oriental Problem' (1870); 'Letters on Russia's Present Position' (1881); and many similar writings.

Fadienskoi, a Russian island of the Arctic Ocean, in the province of Yakatsk. It is 100 miles long by about 40 broad. The climate is very cold the greater part of the year; but the island is inhabited.

Fæces, the residue of food, combined with the intestinal secretions, as it passes from the body. After chyme has passed into the large intestine it is then termed fæces. During health fæces consist largely of the undigested portions of the food taken into the body. They contain microscopically many epithelial cells from different parts of the intestinal canal; shreds of mucus, bits of meat-fibre, the character of which depends upon the ingested food, and which can be determined by the microscope; vegetable detritus consisting largely of parenchymatous and vascular tissues, plant-hairs, etc.; fat-globules; bacteria of many kinds; bile pigments; and other organic residues. As the chemistry of the fæces will vary widely according to the diet, charts of chemical composition are worthless. The consistency of the fæces also widely varies. Normally, fæces should be semi-solid; if too hard, constipation is probable; if too soft and watery, indigestion may be present, or some degree of colitis (q.v.). Large quantities of mucus indicate a colitis. The color of the fæces is of much importance in determining whether the normal functions of the intestine are being carried on. In health the fæces should vary from a light to an umber brown, white to yellow fæces indicating lack of bile-excretion or loss of fat-digestion. Very black fæces often result from excessive bile-elimination, but such are more likely to be present when the drinking-water contains small amounts of mineral constituents, notably iron. Many drugs modify the color of the fæces. In children, green to greenish stools indicate either the presence of certain pigment forming bacteria, or they mean that there is excessive fermentation or putrefaction of the intestinal contents, leading to excess of oxidation of the bile-pigments: In either case castor oil is an excellent corrective. Tarry fæces, resembling coffee-grounds in color, usually indicate the presence of blood high up in the intestinal canal. If bleeding occurs in the large intestine or rectum, red is the prevailing tinge. Small quantities of blood color the fæces orange, like paprika. Cocoa and huckleberries cause a coloration of the fæces that may be mistaken for blood. Colorless or gray-colored stools usually indicate some form of biliary obstruction; or, perhaps from fatty indigestion, an excess of fat passed either from lack of bile-emulsion action or from loss of fat-absorption. Children taking cod-liver oil often have light-colored stools. These should be carefully studied to determine if digestion of the oil is taking place. Disturbance of the functions of the pancreas may also cause light-colored or fatty stools. The study of the color of the stools is of immense practical importance in medicine, and careful observation of this matter by the patient may be of immense service to the physician. See INTESTINES. Consult Conner, 'Medical News' 30 Aug. 1902.

Faed, fād, **John,** R.S.A., Scottish artist: b. Burley Mill, Kirkcudbrightshire, 1820; d. Gatehouse-of-Fleet, Scotland, 22 Oct. 1902. In 1841 he went to Edinburgh to study, soon won a considerable reputation, and was elected associate of the Royal Scottish Academy in 1847, becoming full academician four years afterward. In 1851 he exhibited a work entitled 'The Cruel Sisters,' and this was followed by 'The Cotter's Saturday Night' (1854); 'The Philosopher' (1855); 'The Household Gods in Danger' (1856); 'Job and his Friends' (1858); and 'Boaz and Ruth' (1860). Going to London in 1862, he began to exhibit in the Royal Academy also, some of his pictures shown since that date being: 'Catherine Seyton' (1864); 'Old Age' (1867); 'John Anderson, my Jo' (1869); 'After the Victory' (1873); 'The Morning before Flodden' (1874); 'Blenheim' (1875); 'In Memoriam' (1876); 'The Old Basket-Maker' (1878); and 'The Poet's Dream' (1882). His work invariably displays careful drawing, but his coloring is somewhat hard.

Faed, Thomas, Scottish artist: b. Burley Mill, Kirkcudbrightshire, 8 June 1826; d. London, 22 Aug. 1900. He was a brother of John Faed (q.v.), and at an early age became known as a clever painter of rustic subjects. The subjects of his brush are for the most part domestic or pathetic, and in these he has attained a success that emulates that of Wilkie. Among his principal works are: 'Sir Walter Scott and his Friends' (1849); 'The Mitherless Bairn' (1855); 'The First Break in the Family' (1857); 'Sunday in the Backwoods' (1859); 'His Only Pair' (1860); 'From Dawn to Sunset' (1861); 'The Last o' the Clan' (1865); 'Pot Luck' (1866); 'Worn Out' (1868); 'Homeless' (1869); 'The Highland Mother'

(1870); 'Winter' (1872); 'Violets and Primroses' (1874); 'She Never Told her Love' (1876); and 'Maggie and her Friends' (1878).

Faenza, fä-en'zä (ancient Faventia), Italy, city, in the province of Ravenna, 19 miles from the city of Ravenna. It is noted for its glazed earthenware, called Faience (q.v.), the manufacture of which has flourished here for centuries. Others of its manufactures are majolica, silk goods, and refined sulphur. In the neighborhood are ferruginous and saline springs of considerable repute. Faenza is connected with the Adriatic by the Zanelli Canal, opened in 1782. It claims to be the birthplace of Torricelli. Its history extends into the times before the Christian era, and many changes in government took place before 1509, when it was annexed by Julius II. to the States of the Church. In 1860 it became a part of the Kingdom of Italy. Pop. 13,998; of the commune, 40,400.

Faerie Queene, The, a famous metrical romance by Edmund Spenser, dedicated to Queen Elizabeth, and published in 1590. The poet was already known by his 'Shepherd's Calendar,' but the appearance of the first three books of the 'Faerie Queene' brought him fame. The last three books appeared in 1595–6. The poem is an allegory, founded on the manners and customs of chivalry, with the aim of portraying a perfect knight.

Faeroe Islands. See Faroe Islands.

Fafnir, fäf'nēr, in the mythology of the Nibelungenlied, a son of the magician Hreidmar. In the form of a dragon he guarded the gold which was paid in atonement for the death of Otr, and was slain by Siegfried.

Fagel, fä'hĕl, **Frans Nicolaas,** Dutch soldier: b. Nimwegen 1645; d. Shiys 23 Feb. 1718. He was a nephew of Gaspar Fagel (q.v.), entered the military service in 1672. He distinguished himself in the battle of Fleurus 1690, and the famous defence of Mons 1691 was directed by him. He also displayed great military talent at the siege of Namur, at the capture of Bonn, and in Portugal 1703, in Flanders 1711 and 1712, at the battles of Ramillies (1706) and Malplaquet (1709).

Fagel, Gaspar, Dutch statesman: b. The Hague 1629; d. there 15 Dec. 1688. He was one of the negotiators on the part of Holland in the Peace of Nimwegen (1678), to the conclusion of which he appears to have been personally opposed. He contributed, as much as his position enabled him to do, to the enterprise of William of Orange upon England, and prepared the expedition by which he was enabled to take possession of the crown of that country, although he did not live to witness the success of the undertaking.

Fagerlin, fä'gėr-lēn, **Ferdinand Julius:** b. Stockholm 5 Feb. 1825. In 1854 he began his art studies and entered the Academy of Stockholm; thence he passed to Düsseldorf, and finally became a pupil of Couture at Paris. From Düsseldorf he started on a professional journey northward, for the purpose of studying sea and coast life in Holland. The pictures he then painted are true to nature, subtile in characterization, and abound in wholesome humor.

Fagin, fā'gin, a despicable Jew in Dickens' 'Oliver Twist.' He is represented as training up children in crime in order to profit by their thievish practices, and condemned to be hanged for receiving stolen goods.

Fagnani, fän-yä'nē, **Joseph,** Italian painter: b. Naples, Italy, 1819; d. 1873. He studied at Vienna and Paris, and came to the United States with Sir Henry Bulwer in 1849; here he painted 'The Nine Muses' (portraits of New York women), now in the Metropolitan Museum. He also painted many European celebrities.

Fagot, a bundle of sticks or small branches of trees bound together. In times of religious persecution, the fagot was a badge worn on the sleeve of the upper garment of such persons as had abjured heresy, being put on after the person had publicly carried a fagot to some appointed place, by way of penance. Among military men in England, fagots were persons hired by officers whose companies were not full, to muster and hide the deficiencies of the company, and thus cheat the government.

Fagot-vote, in Great Britain, is a vote procured by the purchase of property under mortgage, or otherwise, so as to constitute a nominal qualification without a substantial basis. Fagot-votes are chiefly used in county elections. The way in which they are usually manufactured, namely, by the purchase of a property which is divided into as many lots as will constitute separate votes, and given to different persons, has given rise to the name. Sometimes properties are bought in this way, and held for the sake of the vote.

Fagot-worm, a caterpillar of a moth of the genus *Eumeta,* which in Ceylon is common on the coffee-trees. It forms a pupa case of silk covered with small sticks, so that it looks like a bundle of fagots; and local folk-lore explains that these worms are the abode of the souls of persons who in their lifetime were thieves of firewood. These moths are related to the bag-worm moths (q.v.).

Fagotto, fa-got'tō, a brass wind instrument, blown with a reed, which can be taken in pieces and carried like a bundle of fagots, hence the name; a bassoon (q.v.).

Faguet, Emile, ā-mēl' fä-gā', French critic: b. La Roche-sur-Yon, France, 17 Dec. 1847. He has published 'French Tragedy of the 16th Century' (1883); 'Corneille' (1888); 'The Great Masters of the 17th Century' (1885); 'Madame de Maintenon as a Teacher,' etc.

Fagus, the typical genus of the Beech family (*Fagaceæ*). The genus has four species, natives of the Northern hemisphere, only one of which, the common beech (*F. americana*), is native of the United States. All the species are trees with smooth gray bark and serrate leaves, the flowers and leaves appearing together. The name is from the Greek, to eat, referring to the edible nuts. See Beech.

Fahaka, an edible globe-fish (*Tetiaodon fahaka*), singular in inhabiting the fresh waters of the Nile. See Globe-fish.

Fahlcranz, fäl'kränts, **Karl Johann,** Swedish landscape-painter: b. Sprengel, Stora-Tuna, in the län of Falun, 29 Nov. 1774; d. Stockholm 1 Jan. 1861. Studying nature diligently, he became a self-educated artist. He was acquainted only with northern scenery, but has given it with great fidelity and spirit. His

Fahrenheit, fä'ren-hīt, **Gabriel Daniel,** German physicist: b. Dantzic 14 May 1686; d. Amsterdam 16 Sept. 1736. He settled in Holland, where in 1720 he first conceived the idea of using quicksilver instead of alcohol in thermometers — a discovery by which the accuracy of the instrument was very much improved. He took, as the limit of the greatest cold, that which he had observed at Dantzic in the winter of 1709. The space between the point to which the quicksilver fell at this temperature, and that to which it rose in boiling water, he divided into 212 parts. About 1724 he discovered the fluctuation of the boiling point of water, which he had made one of the fixed points of his thermometer. Fahrenheit's thermometer owed its beginnings to the invention of a thermometer by Newton, described in the 'Philosophical Transactions' for 1701. Newton's instrument was a tube filled with linseed oil, and the starting-point of the scale was the temperature of the human body, which Newton called 12. Newton divided the space between his datum and the freezing-point of water into 12 equal parts, and stated that the boiling-point of water would be about 30 of these degrees on the scale. Fahrenheit, when he began to work with Newton's thermometer, did not find the scale minute enough for his purposes. He therefore first doubled the number of degrees, making the scale number 24 instead of 12. Finding he could, by mixing ice and salt, obtain a temperature below freezing, Fahrenheit next adopted this for his starting-point and counted 24 degrees up to body heat, making the freezing-point 8 and calling boiling water 53. Later on he again divided his degrees into four. It will be seen that if the above figures are multiplied by four, the result is the thermometric scale called after him which is still in use.

Faidherbe, Louis Léon César, loo-ē lā-ôn sā-zär fā-dārb, French general and author: b. Lille 3 June 1818; d. Paris 29 Sept. 1889. Entering the army in 1840, he became lieutenant in 1842. From 1854 till 1861, and again from 1863 till 1865, he was governor of Senegal, in which capacity he considerably extended the French possessions there. After the fall of Napoleon III. he was summoned by the government of National Defense to France and appointed commander of the army of the north. In the latter part of his life he went on a mission to Egypt to study the monuments and hieroglyphics. He wrote valuable monographs on Senegal, the Sudan, and other parts of Africa, including 'L'Avenir du Sahara et du Sudan' (1863); 'Collection Complète des Inscriptions Numidiques' (1870); 'Nouvelles Inscriptions Numidiques' (1872); 'Langues Sénégalaises' (1887); and 'Le Sénégal: la France dans l'Afrique Occidentale' (1889). On the Franco-German war he published 'Campagne de l'Armée du Nord en 1870–1' (1872).

Faïence, fā-äns, glazed pottery. The name is derived from the town of Faënza in Italy and was applied to pottery by the French under the following circumstances. About the year 1578 the Duke of Nevers in France was desirous of establishing an atelier for the production of glazed pottery and he secured a skilled workman named Gambyn. This man was an Italian and had learned his art in Faënza. When, therefore, he produced similar pottery at Nevers it was known as Faënza ware and, subsequently, as faïence, a Gallicized form of the word. The term is now generally applied to ornamental pottery of which the glaze forms a marked feature. Faïence is distinguished from porcelain by the fact that it is produced at a much lower temperature, being made, for the most part, of common and often colored clays. Most of the decorative pottery produced in America falls within this class, as for instance the Rookwood, Grueby, Merrimac, and Volkmar wares. The term faïence is not usually applied to any form of tableware though there seems to be no good reason why plates should be classed apart from vases if they are similar in technical quality. See Ceramics; Pottery.

Faillon, Michel Etienne, mē-shel ā-tē-en fä-yôn', French historical writer: b. Tarascon, France, 1799; d. Paris 25 Oct. 1870. He was a Sulpician and visited Canada in 1854 to investigate the houses of that order. He wrote lives of noted French Canadian religionists, and a comprehensive history of the French in Canada, three volumes of which appeared before his death.

Failure. See Bankrupt.

Fainéants, fā-nā-än, or **Do-nothing Kings,** the name given in French history to some of the Merovingian sovereigns, who were the puppets of the mayors of the palace. The last of these kings was Childeric III.

Faint (syncope), a peculiar form of sudden loss of consciousness. Impoverishment of the blood, lowered vitality from any cause, an overwrought nervous system, and disease of the circulatory system predispose to such attacks. The immediate cause is an anæmia of the brain. This sudden cerebral anæmia is most frequently due to shocking sights, sickening smells, pains, or fears. The attack may be ushered in by a period of nausea, sighing respiration, or "faint feeling." Immediate lowering of the head below the rest of the body will frequently ward off further trouble. Most commonly the attack is very sudden, the face becoming absolutely bloodless and having a deathlike calm; the pulse is weak or imperceptible, the breathing very shallow. In true syncope spasms are not present, neither is voiding of the urine or fæces. Fatal termination is rare, consciousness ordinarily being restored in a few moments if prompt measures are taken. The patient must be placed in a recumbent position, with the head as low or lower than the rest of the body; constricting clothing should be loosened; and water may be slapped on exposed parts. Smelling-salts held to the nose are of value. Later mild stimulants may be used to restore normal condition; but resumption of vertical position should be postponed as long as practicable.

Faioum, or **Fayoum.** See Fayum.

Fair, James Graham, American capitalist: b. near Belfast, Ireland, 1831; d. San Francisco 1894. He emigrated to America in 1843 and went to California in the famous '49 year. He amassed great wealth by mining in Nevada, to which he went in 1860. He was elected in 1881 as a Democrat to the United States Senate in which he served one term.

Fair God, The, a romance by Lew Wallace 1873. It is a story of the conquest of Mexico by the Spaniards, its scene laid upon Aztec soil, in the early part of the 16th century. The title is derived from Quetzalcoatl, "the fair god," the Aztec deity of the air.

Fair Haven, Mass., town in Bristol County on Buzzard's Bay, at the mouth of the Acushnet River, and on the New York, N. H. & H. R.R.; 60 miles south of Boston, and opposite New Bedford, with which it is connected by bridges. Here are the Millicent Public Library, several banks, churches, and other public buildings. It has manufactories of glass, castings, nails, and tacks. Many buildings of architectural merit, which render Fair Haven one of the most attractive towns of the State, were erected by Henry H. Rogers (q.v.) as memorials to members of his family. One architectural group, a fine example of Tudor architecture, consisting of a church and two other buildings, is considered a model of beauty. Pop. (1900) 3,567.

Fair Havens (Gr. Καλοὶ Λιμένες, *Kaloi Limenes*), an anchorage on the southern coast of Crete, five miles east of Cape Litino. It is of small size and amply sheltered from western winds. The only mention of it by ancient writers is that by Paul (Acts xxvii. 8), whose well-known shipwreck occurred after departure from Fair Havens for Phenice or Phœnix. It is probable that there was no town at that point, although, as stated in Acts, Lasea was but a short distance away.

Fair Head, or **Benmore,** a precipitous promontory of the north coast of county Antrim, Ireland, opposite Rathlin Isle. It rises 636 feet above the sea, and consists of carboniferous strata, overlaid by greenstone columns, 20 to 30 feet thick, and 280 to 300 feet high.

Fair Isle, a solitary Shetland island lying midway between Shetland and Orkney, and 30 miles southwest of Lerwick. It is three miles long and two miles broad. The men employ themselves chiefly in fishing, and the women in knitting the well-known Shetland hosiery. They are said to have acquired this art from the Spanish seamen whose ship, belonging to the Armada, was wrecked here in 1588. Pop. 223.

Fair Maid of Perth, The, a novel by Sir Walter Scott, published 1831. The time is the reign of King Robert III. of Scotland; whose scapegrace son David, the crown prince, is the connecting link in the story between the nobility and the burgher-folk of the city of Perth. Like all Scott's novels, 'The Fair Maid of Perth' contains fine descriptions of scenery, and stirring accounts of battle; and unlike many of his plots, this one allows the "course of true love" to run comparatively smooth.

Fair Oaks and Darbytown Road, Engagement at (SECOND BATTLE OF FAIR OAKS)—On 27 Oct. 1864, Gen. Grant began a movement on the Petersburg lines, to seize the South-side railroad, and as a support to the movement, had ordered Gen. Butler to make a demonstration north of James River on Richmond. Parts of three divisions of the Tenth corps, under Gen. Terry, six brigades of the Eighteenth corps, under Gen. Weitzel and Gen. Kautz's cavalry division were designated for the movement. Terry was to make a demonstration along the Darbytown road, under cover of which Weitzel was to push through White Oak Swamp to reach the Williamsburg road and seriously threaten Richmond. The columns started from camps, near Chaffin's farm, very early on 27 October. Terry reached the Darbytown road, a part of his command crossed over to the Charles City road and advancing on both roads, a little before 8 A.M. engaged the Confederates in their entrenchments from the New Market road to the Charles City road. Weitzel, after a march of 16 miles, crossing both the Darbytown road and Charles City road and at 1 P. M. reached the Williamsburg road at Heintzelman's old works, on the battle-field of 31 May 1862, and pushed at once down the road one and a half miles toward Richmond, and came upon the Confederate works, which appeared to be feebly held by a small body of dismounted cavalry and three guns. Weitzel prepared to attack, first sending a brigade of colored troops across the York River railroad to find and turn the Confederates' left near the New Bridge road. The defenses north of the James were held by Gen. Longstreet, with the divisions of Gens. Hoke and Field, some "local defense" troops, under Gen. Ewell, and Gen. Gary's cavalry brigade. These were posted with reference to defense along the river roads. As soon as Longstreet detected Weitzel's movement he ordered Field's division to move to the left and it formed on either side of the Williamsburg road. It was 3.30 P.M. when Weitzel, with two brigades, and others in support, advanced on either side of the road, over open ground, and was met with an unexpected heavy fire of musketry and artillery. His troops almost reached the works, but were repulsed with a severe loss, in killed, wounded, and missing. Soon after dark Weitzel withdrew after losing over 1,000 men. While Weitzel was engaged, Terry, at 4 P. M., was ordered to press his demonstration and carry the entrenchments. He made the attempt and was repulsed. On the next day the expedition returned to camp. The Union loss was 905 killed and wounded, and 698 missing. The Confederate loss was comparatively small; Field's division and Gary's brigade reported 64 killed, wounded and missing. The entire loss probably did not exceed 100. See Humphrey, 'The Virginia Campaign of 1864–5.' E. A. CARMAN.

Fair Oaks (Seven Pines), Battle of. After the battle of Williamsburg (5 May 1862) the Army of the Potomac, under Gen. McClellan, advanced cautiously up the Peninsula, established a base at White House, and 20 May his advance crossed the Chickahominy at Bottom's Bridge, and the entire Fourth corps under Gen. E. D. Keyes crossed on 23, taking position 25 May at Seven Pines, on the main road to Richmond, about five miles distant. The Third corps, under Gen. S. P. Heintzelman, crossed 25 May. This left on the north bank, the Second, Fifth and Sixth corps, commanded respectively by Gens. E. V. Sumner, Fitz John Porter, and Wm. B. Franklin. McClellan began to rebuild destroyed bridges and to perfect communication between the two wings of his army, astride the Chickahominy. The movements of McClellan north of the Chickahominy and information from his cavalry, convinced Gen. Joseph E. Johnston, the Confederate commander, that Gen. McDowell with a strong corps was about to join McClellan from Fredericksburg, upon which, 28 May, he ordered up Gen. Huger's division from Petersburg and Drewry's Bluff and suggested to Gen. Lee that every available command should be concentrated at Richmond. On 25 May Gen. Casey's division of the Fourth corps advanced from Seven Pines to Fair Oaks, about three fourths of a mile and threw up works covering the road, and on 30 May two brigades of Kearny's division, Third corps, were advanced about a fourth of a mile in front of Savage Station to within supporting distance of Casey. Gen. Couch's division, Fourth corps, was at Seven Pines, and Gen. Hooker's division, Third corps, on the border of White Oak Swamp. Johnston, from his works, three miles in front of Richmond, watched McClellan's cautious advance. A reconnoissance 30 May developed the fact that Keyes had advanced his lines to Fair Oaks; Johnston saw his opportunity and issued orders for an attack next day. The Army of the Potomac, 31 May, had 127,166 officers and men, of whom 98,008 were present for duty, and it had 280 guns. Johnston had about 63,000 effectives and was not well supplied with artillery. Johnston purposed to throw 23 of his 27 brigades against Keyes and Heintzelman and with four brigades along the line of the river from New Bridge to Meadow Bridge prevent the rest of McClellan's army from crossing the stream. He purposed to move the 23 brigades by the Charles City, Williamsburg, and Nine Mile roads, crush Keyes' corps and drive it back in disorder on Heintzelman, and capture or destroy those two corps before any assistance could reach them from the north bank of the stream. There was some misunderstanding of orders on the morning of the 31 and much consequent delay but, at noon, Gen. D. H. Hill's division of four brigades, deployed in double line on either side of the Williamsburg road, advanced on Casey's division at Fair Oaks and after a severe fight of two hours drove it back upon Couch's division at Seven Pines. Hill now received a reinforcement of one brigade, and two brigades of Kearny's division came to the assistance of Couch and Keyes, and the struggle was renewed at Seven Pines, with the result that the entire Union force was driven back to a line of entrenchments about a mile in the rear, which position was held. Three Union divisions had been engaged and suffered severely, and a part of Couch's division had been cut off. Gen. G. W. Smith, with several Confederate brigades, was observing the Chickahominy, under orders to engage any troops that might cross the stream to assist Keyes and Heintzelman, or, if none came, he was to fall upon the right flanks of the Union lines engaged. After waiting some time and believing that no Union troops would cross to the south bank of the stream, Smith put some of his troops in motion to make the flank attack, but it miscarried from the timely arrival of Sumner on the south bank of the Chickahominy. Sumner, who was nearest Keyes and Heintzelman, heard the sound of battle at 1 o'clock and was at once in the saddle, and ordered his troops under arms. A little later orders came from McClellan that he should be prepared to march at a moment's notice. Without waiting another moment he marched his two divisions to the Chickahominy and paused upon the two bridges, waiting orders to cross them. At 2.30 P. M. the order came to cross. Richardson could get but one brigade of his division over the lower bridge and was obliged to move up and follow Sedgwick's division over the Grapevine Bridge, which swayed and tossed in the river. But the solid column of Sedgwick's infantry, loading it with a weight with which even the angry Chickahominy could not trifle, soon pressed and held it down among the stumps of the trees, which in turn prevented its lateral motion. Once across, Sumner pressed forward on the road, deep with mud, toward Fair Oaks, and came up to Couch, who with four regiments and a battery had been cut off from his division and was holding ground about a half mile from Fair Oaks, with Smith approaching to make his flank attack. But four of Sumner's regiments had formed on Couch when Smith attacked, two more soon followed, and these six regiments, with Couch's, checked all efforts of Smith's four brigades to dislodge them and saved the day at Fair Oaks. Richardson's division came up at nightfall and formed on Sedgwick's left, extending toward a brigade of Heintzelman's corps, while Hooker, coming to the support of the defeated troops on the Williamsburg road, filled vacant spaces in the line. There were now three corps across the Chickahominy in continuous order, ready for action when day should dawn. Near the close of the day Gen. Johnston, the Confederate commander, was severely wounded and relinquished command to Gen. G. W. Smith. On the morning of 1 June, the Union army awaited attack, which was delivered by the Confederates and, on some parts of the line, the fighting was severe, but the advantage remained with the Union troops, who regained most of the ground lost the previous day. On 1 June, Gen. R. E. Lee was placed in command of the Army of Northern Virginia, but did not take direction of affairs on the field until the fighting was over, and 2 June withdrew to the fortifications around Richmond from which Johnston had advanced 31 May. The Union forces engaged at Fair Oaks numbered about 36,000; the Confederates about 32,000. The Union loss was 4,384 killed and wounded, and 647 missing; the Confederate loss was 5,729 killed and wounded, and 405 missing.

Consult: Allan, 'The Army of Northern Virginia in 1862'; 'Battles and Leaders of the Civil War,' Vol II.; McClellan, 'My Own Story'; Michie, 'Life of Gen. McClellan'; 'Official Records,' Vol. XI.; Walker, 'History of the Second Army Corps'; Webb, 'The Peninsula.'

E. A. CARMAN.

Fair Trade, an expression used in Great Britain by certain persons who, professing to be free traders, would still tax goods imported from any country which refuses to accept the principles of free trade. Free traders consider this view as protectionist. They hold that if they can import goods cheaper from a protectionist country than elsewhere, they should be free to reap that advantage even if they cannot export their own goods to that country free of duty. See FREE-TRADE.

Fairbairn, Andrew Martin, English theologian: b. near Edinburgh 4 Nov. 1838. Having qualified for the ministry of the Evangelical Union, he was appointed to a church of that denomination at Bathgate in 1860. Accepting a similar charge in Aberdeen in 1872, he ministered there till appointed in 1877 to the principalship of Airedale Independent College, Bradford. On the foundation of Mansfield College, the Congregational Theological College at Oxford, in 1886, he was appointed principal, a post which he still occupies. He delivered the Aberdeen Gifford Lectures of 1892–4, and the Lyman Beecher Lectures at Yale in 1892. His most important works are: 'Studies in the Philosophy of Religion and History' (1876); 'Studies in the Life of Christ' (1881); 'The City of God' (1882); 'Religion in History and in Modern Life' (1884, revised and enlarged edition 1893); 'Christ in the Centuries' (1892); 'The Place of Christ in Modern Theology' (1893); 'Catholicism, Roman and Anglican' (1899).

Fairbairn, Sir **William,** Scottish civil engineer: b. Kelso, Scotland, 19 Feb. 1789; d. 18 Aug. 1874. He entered business in Manchester, England, in 1817. He constructed the first iron ship in England and afterward his firm built over 100 iron vessels. He was associated with Robert Stephenson in designing and building the great tubular bridge over Menai Strait. He was the author of 'Mills and Millwork'; 'Iron, Its History and Manufacture'; 'Application of Iron to Building Purposes'; 'Iron Shipbuilding'; 'Useful Information for Engineers'; 'An Experimental Inquiry into the Strength, Elasticity, Ductility, and other Properties of Steel' (1869); etc.

Fairbank, Calvin, American clergyman: b. Pike, N. Y., 3 Nov. 1816; d. Angelica, N. Y., 12 Oct. 1898. He was an ardent abolitionist, and during 1837–9, aided 23 slaves to escape across the Ohio River. In 1843 he raised $2,275 to secure the liberty of a nearly white slave girl who was to be sold at auction at Lexington, Ky. In 1844 he opened the way for the escape of the Hayden family, for which offense he suffered five years' imprisonment. Later he was again detected in violation of the Fugitive Slave Law, and sentenced to 15 years' imprisonment at Frankfort, where he was cruelly treated, receiving about 35,000 lashes on his naked body. In 1864 he was set at liberty after spending more than 17 years in jail. He published 'How the Way Was Prepared' (in which he told the story of his own life).

Fairbanks, Arthur, American teacher and author: b. Hanover, N. H., 1864. He was graduated at Dartmouth College in 1886, and received a doctorate from Freiburg, Germany. He has taught at Dartmouth, Yale, and Cornell, and since 1900 has been professor of Greek literature in the State University of Iowa. Among his writings is an 'Introduction to Sociology' (1901) which has been translated into Japanese.

Fairbanks, Charles Warren, American lawyer and senator: b. near Unionville Centre, Union County, Ohio, 11 May 1852. His father, Lorison M. Fairbanks, was a Vermonter, and was one of the early pioneers who settled in the west in 1836 and helped to hew out of the wilderness the great Buckeye State. The son's earliest life was spent in toil on the farm, from sunrise to sunset, and in quiet hours of study during the evening. He was naturally studious, and early destined himself to the career of a lawyer. After passing through the district school he attended classes in the Ohio Wesleyan University, where he was graduated with distinction in 1872. During his senior years at college he edited the 'Western Collegian,' the college journal. After leaving the Wesleyan University he went to Cleveland, as Associated Press agent; meanwhile studying law. In 1874 he was admitted to the bar of the supreme court of Ohio at Columbus, and in the same year removed to Indianapolis, Ind. In this city he has lived ever since, as a practising lawyer. While never holding public office until elected to the Senate, he was chairman of the Indiana State Convention in 1892 and again in 1898. In 1893 he was unanimously chosen as the nominee of the Republican party for United States senator, but was defeated at the polls by the Democratic candidate, David Turpie, although receiving his entire party vote. He was delegate-at-large to the Republican National Convention at St. Louis in 1896, and was temporary chairman of the convention. He was appointed a member of the United States and British Joint High Commission, which met in Quebec in 1898 for the adjustment of Canadian questions, especially relating to the seal-fisheries of Alaska. He was elected to the United States Senate 30 Jan. 1897, and at the expiration of his term was re-elected. In Nov. 1904 he was elected Vice-President on the Republican ticket. Since 1885 he has been a trustee of the Ohio Wesleyan University.

Fairbanks, Henry, American inventor: b. St. Johnsbury, Vt., 6 May 1830. He is a son of Thaddeus Fairbanks (q.v.), and was graduated at Dartmouth College in 1853, and at Andover Theological Seminary in 1857. He was ordained in 1858; held pastorates in Burke and Barnet, Vt., and in 1859 was professor of physics, and later of history, at Dartmouth. He became identified with the manufacturing firm of E. & T. Fairbanks & Co., in 1868; and subsequently gave much of his time to mechanical experiments, and patented several inventions relating to the manufacture of scales.

Fairbanks, Thaddeus, American inventor: b. Brimfield, Mass., 17 Jan. 1796; d. St. Johnsbury, Vt., 12 April 1886. He settled in St. Johnsbury in 1815, and there worked with his father in a saw and grist mill, and also in the manufacture of carriages. In June 1831 he patented the platform scales bearing his name. Afterward about 50 different improvements were made on these scales, which have been sold in all parts of the world.

Fairbury, Nebr., city, county-seat of Jefferson County; on the Little Blue River, the St. Joseph and other branches of the Chicago, R. I. & P. System; about 60 miles southwest of Lincoln. It is situated in a good agricultural region, and its chief manufactures are flour and dairy products. A large nursery is just outside the city limits. Pop. (1900) 3,140.

Fairchild, Ashbel Green, American clergyman; b. Hanover, N. J., 1 May 1795; d. Smithfield, Pa., 1864. He wrote many contributions to the religious press. His most popular work, 'The Great Supper,' was translated into German and had an immense sale. He also published 'Baptism'; 'Faith and Works'; and 'Confession of Faith.'

Fairchild, Charles Stebbins, American financier; b. Cazenovia, N. Y., 30 April 1842. He was graduated at Harvard University in 1863; admitted to the bar in 1865; became deputy attorney-general of New York in 1874, and attorney-general in 1876. After spending some time in Europe he settled in New York city in

1880, where he practised law till 1885. He was assistant secretary of the treasury 1885–7, and secretary 1887–9. Subsequently he became president of the New York Security and Trust Company.

Fairchild, George Thompson, American educator: b. Brownhelm, Ohio, 6 Oct. 1838. He was graduated from Oberlin College 1862, and from Oberlin Theological School 1865; was professor of English literature Michigan Agricultural College 1879–97; and has been vice-president of Berea College since 1898. He entered the Congregational ministry in 1871 and has published 'Rural Wealth and Welfare: Economic Principles Illustrated and Applied in Farm Life' (1900).

Fairchild, Herman Le Roy, American educator; b. Montrose, Pa., 29 April 1850. He was graduated at Cornell University in 1874; was secretary of the New York Academy of Science in 1885–88; became president of the Rochester Academy of Science in 1889, secretary of the Geological Society of America in 1890, and vice-president in 1898. He has been professor of geology at the University of Rochester from 1888, and has published a 'History of the New York Academy of Sciences' (1887).

Fairchild, James Harris, American educator: b. Stockbridge, Mass., 25 Nov. 1817. He was elected president of Oberlin College in 1866, after a service of 26 years as tutor, professor of languages, professor of mathematics, and professor of moral philosophy and theology. Besides editing the 'Memoirs of Charles G. Finney' (1876) and Finney's 'Systematic Theology' (1878), he was the author of 'Moral Philosophy' (1869); 'Oberlin, the Colony and the College' (1883); 'Elements of Theology, Natural and Revealed'; and 'Woman's Right to the Ballot' (1870). He resigned the presidency of Oberlin in 1889.

Fairchild, Lucius, American military officer: b. Kent, Ohio, 27 Dec. 1831; d. Madison, Wis., 23 May 1896. At the beginning of the Civil War he enlisted as a private in the Federal army, and in August 1861, was appointed a captain in the regular army, and major in the volunteer army. He took part in the battles of Bull Run and Antietam, and led the charge up Seminary Hill at Gettysburg, where he lost his left arm. He was promoted brigadier-general in 1863, but resigned to serve as secretary of state of Wisconsin. He was afterward elected governor, and served six consecutive terms. In 1886 he was chosen commander-in-chief of the Grand Army of the Republic.

Fairfax, Donald McNeill, American naval officer: b. Virginia 19 March 1821; d. Hagerstown, Md., 10 Jan. 1894. During the Mexican war he participated in the capture of Mazatlan and Lower California. In 1861 he had personal charge of the transfer of Messrs. Mason and Slidell and their secretaries from the «Trent,» a British mail ship, to the «San Jacinto.» He later took part in the chief naval operations in Charleston harbor; was promoted rear-admiral 11 July 1880; and retired 30 Sept. 1881.

Fairfax, Edward, English poet: b. Denton, England, about 1580; d. near Otley, England, January 1635. He made a metrical translation 'Godfrey of Boulogne' (1600), of Tasso's 'Jerusalem Delivered,' and dedicated it to Queen Elizabeth; it was highly esteemed by James I., and is still highly valued; and on this rather than on his own «Eclogues» the fame of Fairfax as a poet rests. He is also author of a 'Discourse on Witchcraft,' first published in 1858.

Fairfax, Thomas, Lord, English general: b. Denton, Yorkshire, 17 Jan. 1611; d. Nun Appleton, Yorkshire, 12 Nov. 1671. Fairfax warmly espoused the cause of Parliament, and in April 1642, presented to Charles a petition of the people imploring him to be reconciled to his subjects. The same year he was appointed general of the horse, and in 1644, together with Essex, Waller, and Manchester, he held a chief command in the English army sent to co-operate with the Scots. The credit of the battle of Marston Moor has, by some authorities, been divided between Leslie and Cromwell, but, according to others, Fairfax is also entitled to share in it. On the Earl of Essex resigning the command of the parliamentary army in 1645, Fairfax was made general-in-chief in his room. He insisted on the command of the horse being given to Cromwell. When he took Oxford the first thing he did was to set a guard upon the Bodleian Library, an act for which he deserves the gratitude of posterity. He subsequently, in November 1647, was engaged with Cromwell in putting down the levellers in the army, and in the following year captured Colchester, and caused Sir Charles Lucas and Sir George Lisle to be tried by court-martial and shot. Being ordered to march against the Scottish Presbyterians, he positively declined the command and Cromwell was appointed (June 26, 1650) to succeed him. He was appointed one of the lay church commissioners in 1654, and was a member of Cromwell's first Parliament. He assisted Monk against Gen. Lambert, and co-operated in the restoration of Charles II., being one of the committee charged to secure his return.

Fairfax, Thomas, 6th Baron of Cameron: b. England 1691; d. Greenway Court, Frederick County, Va., 12 Dec. 1782. He was educated at Oxford and was a contributor to Addison's 'Spectator.' He came to America and settled on a vast landed estate in Virginia inherited from his mother, a daughter of Lord Culpeper. It was there, at Greenway Court, that Washington first met him, and between the two there sprang up a warm friendship.

The 11th Lord Fairfax and baron of Cameron who succeeded his brother to the baronetcy in 1869, and who died in Northampton, Md., 28 Sept. 1900, like his American predecessors, made no claim to the title.

Fairfield, Sumner Lincoln, American author: b. Warwick, Mass., 25 June 1803; d. New Orleans, La., 6 March 1844. He began the publication of the 'North American Magazine' in 1833; and continued to edit and publish it for five years. His published volumes include: 'Lays of Melpomene' (1824); 'Cities of the Plain' (1828); 'Poems and Prose Writings' (1840), and 'Select Poems' (1860).

Fairfield, Conn., town, port of entry, in Fairfield County; three miles southwest of Bridgeport; on the Long Island Sound, the New York, N. H. & H. R.R. The chief manufactures are paper, rubber goods, and machinery. It has good public buildings, two libraries, and four buildings which date from Revolutionary times. The first settlement was made in 1869 and the town was incorporated the same year. It was the scene of several Indian and Revolutionary battles, and in 1779 was almost wholly burned by the Hessians and Tories. Pop. (1900) 4,489. Consult: Osgood, 'Centennial Commemoration of the Burning of Fairfield.'

Fairfield, Ill., city, county-seat of Wayne County; 123 miles southeast of Springfield; on the Louisville, E. & St. L. and the B. & O. Southwestern R.R.'s. The manufactures are chiefly flour, lumber, and dairy products. The trade is in agricultural products. It is the site of the Hayward Collegiate Institute. Pop. (1900) 2,338.

Fairfield, Iowa, city, county-seat of Jefferson County; 48 miles northwest of Burlington; on the Chicago, R. I. & P. and the C., B. & Q. R.R.'s. The principal manufactures are brooms, tile, agricultural implements, machinery, furniture, carriages, flour, and dairy products. The electric-light plant and the water-works are owned by the city. The Parsons College, under the auspices of the Presbyterian Church, was founded here in 1875. The first settlement was made in 1839. Pop. (1900) 4,689.

Fairhaven, Wash., city in Whatcom County; on an arm of Puget Sound; 42 miles northeast of Victoria, in Canada, and 88 miles north of Seattle; on the Northern P. and the G. N. R.R.'s. It is near a good agricultural region; its principal manufactures are canned salmon, tin cans, flour, and lumber. Fairhaven was first settled in 1888. Its natural advantages combined with its opportunities for railroad transportation make its outlook most promising. Pop. (1900) 4,228.

Fairholt, Frederick William, English artist and author: b. London 1814; d. there 3 April 1866. He published: 'Costume in England: a History of Dress to the Close of the 18th Century' (1846); 'The Home of Shakespeare Illustrated and Described' (1847); 'Remarkable and Scientific Characters' (1849); 'Dictionary of Terms in Art' (1854); etc.

Fairmont, W. Va., city, county-seat of Marion County; on the Monongahela River and the Baltimore & O. R.R.; 75 miles southeast of Wheeling. It is the site of a State Normal School; its principal manufactures are glass, machinery, cigars, lumber, and iron products. It has considerable trade in coal, coke, and manufactured articles. Pop. (1900) 5,655.

Fairmount College, a coeducational preparatory school and college, under the auspices of the Congregationalist Church. It was established in 1892, with assistance from the Boston Education Society. A collegiate department was added in 1895. In 1901 there were 23 professors and instructors, 238 pupils, and 23,000 volumes in the library.

Fairmount Park. See PHILADELPHIA.

Fairs and Periodical Markets. A fair is a periodical meeting of merchants in an open market held at a particular place, and generally for the transaction of a particular class of business. The origin of fairs is obviously to be traced to the convenience of bringing together at stated times the buyers and sellers of the stock-produce of a district. Fairs are generally held in or near towns, but from their nature are specially adapted to the convenience of country dealers and their customers. Two curious facts are to be noted in the history of fairs. In Europe the numerous festivals of the church afforded the most favorable opportunity for the establishment of these markets. This association is indicated in the German name of a fair, which is identical with that used for the ceremony of the mass. A fair generally brings a concourse of people into the town in which it is held, and gives it something of a holiday appearance. Advantage has frequently been taken of this concourse, either by the persons assembled themselves or by the purveyors of various amusements, to add entertainment to business, and as the business of a particular fair declined it has often, instead of being abandoned, been gradually converted into a periodical opportunity for a saturnalia of amusement. Thus religion, business, and diversion have come to be associated in the idea of a fair.

In the Middle Ages fairs were specially privileged and chartered by princes and magistrates, special temporary tribunals were even established for their use. It was then the custom, which in some places still remains, to make a public proclamation of the commencement and duration of the fair. The goods sold at fairs were then of much greater value, as well as variety, than at present, embracing fabrics of all kinds, as well as jewelry. In some parts of the Continent the practice still prevails of purchasing clothing at fairs. Fairs existed in ancient as well as modern times, and are to be found in all parts of the world. In the East they are of great magnitude and importance. At Mecca, during the annual pilgrimages, and at Hardwar in Ajmir, a resort of pilgrims in Hindustan, two of the greatest fairs of the East, we find again the association between commerce and religion. According to Prescott fairs were regularly held in the principal cities of Mexico every fifth day, being the recognized substitute for shops. A fair for the sale of slaves was held at Azcapozales, near the capital. At the principal fair, held at the City of Mexico, the number of visitors reached 40,000 to 50,000. Here the same arrangement prevailed as in the European fairs of the Middle Ages. A court of 12 judges, clothed with absolute authority, maintained perfect order in this great concourse.

The Easter and Michaelmas fairs at Leipsic, the fairs of Frankfort-on-the-Main, of Lyons in France, and Nijnei-Novgorod in Russia, are among the most important fairs of the present day in Europe. The fairs of Great Britain now mostly consist of the weekly market-days of country towns, and certain great agricultural meetings, or trysts, as they are called in Scotland, chiefly for the sale of cattle and horses, such as the Falkirk Tryst. There are also, especially in Scotland, a considerable number of the hiring fairs. Among the most celebrated of the fairs which have been turned into saturnalia are the celebrated Donnybrook fair in the county of Dublin; Bartholomew and Greenwich fairs, London; and Glasgow fair. The day of these fairs is, however, already past; the tide of modern improvement has long since reached the amusements of the people, and better means of entertainment are now available. In the United States the State fair and county fair, as well as the church fair, are established institutions. See EXHIBITIONS.

Fairweather, Mount, in Alaska, 35 miles northeast of Cape Fairweather. According to accurate observations its height is 14,900 feet above the level of the sea. It is covered with perpetual snow.

Fairy, an imaginary being or spirit of diminutive size, supposed generally to assume a human form, but appearing also in others, and represented as both beneficent and malevolent toward mankind. In the latter case diseases of cattle were frequently attributed to their mischievous operations; and cattle that died suddenly without any apparent cause were commonly said to be elf-shot. Among the Irish peasantry they are termed "the good people" by way of placation. In Poole's 'Parnassus' are given the names of the fairy court: "Oberon, the emperor; Mab, th empress; Perriwiggin, Perriwinkle, Puck, Hobgoblin, Tomalin, Tom Thumb, courtiers; Hop Mop, Drop, Pip, Drip, Skip, Tub, Tib, Tick, Pink, Pin, Quick, Gill, Ion, Tit, Wap, Wim, Nit, the maids of honor; Nymphidia, the mother of the maids." Croker, in his 'Fairy Legends and Traditions of the south of Ireland,' describes them as beings "a few inches high, airy, and almost transparent in body; so delicate in their form that a dewdrop, when they chance to dance on it, trembles, indeed, but never breaks." They are supposed to live in a distinct domain known as Fairyland, and their character and habits as represented in literature may best be learned from the Irish lore and such works as the 'Märchen of the Grimms'; Spenser's 'Faerie Queene,' and Shakespeare's 'Mid-summer Night's Dream.' Belief in fairies has existed from earliest times, and formed part of the superstition of nearly all peoples. Consult: Keightley, 'The Fairy Mythology' (1850). See FOLK-LORE; MYTHOLOGY; PARACELSUS; also such titles as ELVES, KOBOLD, and the like.

Fairy Bluebird, one of the bulbuls (q.v.) of the East Indian family *Pycnonotidæ* and genus *Irena,* familiar in Indian gardens, and justly admired. The commonest species is brilliant turquoise, with black wings, tail and under parts, and coral-red legs and beak. They make a rather rough little nest in a bush and lay two or three speckled eggs.

Fairy Ring, or **Circle**, a ring occasionally observed in pastures, distinguished from surrounding vegetation by being either barer or more luxuriant, and attributed by the peasantry of western Europe to the dancing of the fairies. They are now known to be occasioned by the growth of certain kinds of fungi, which, proceeding outward from a centre, render the soil for a time unfitted for the nourishment of grass, but later fertilize it by their decay.

Fairy Shrimp, a phyllopodous crustacean (*Chirocephalus diaphanus*), occasionally found in fresh-water ponds in Europe. It is about one inch in length, and nearly transparent.

Fairy-tales, stories in which fairies play a part, or which contain other supernatural or magical elements such as mark the folk-tales of 'Puss in Boots'; 'Beauty and the Beast'; 'Hop o' My Thumb'; 'Sleeping Beauty'; and others. Actual fairies seldom appear in traditional fairy-tales so called. Grimm and his successors showed by the study of comparative mythology that these tales are not restricted to Europe alone, but are to be found, in varying forms, among almost all nations. The survival of popular tales is due to their being unconscious growths, to the strict adherence to form shown by illiterate and savage people in recitals, and to the laws of the permanence of culture. There are several theories in regard to the origin of folk-tales. The oldest is the Oriental theory, which traces all back to a common origin in the Vedas. It is true that the germs of most tales are found in the Vedas, but proofs of the Indian origin of stories are lacking; the discovery of tales in Egypt which were written down in the period of the early empire are objections to its acceptance, and the idea of diffusion will not account for similar tales found in Australia, New Zealand, and America. The Aryan theory, supported by Max Müller, Grimm, and others, gives as their origin the explanation of natural phenomena. These nature-myths must not be regarded as originally metaphors; they were primitive man's philosophy of nature, in the days when every object was endowed with a personal life. The tales have enough likeness to show that they come from the same source, and enough difference to show they were not copied from each other. Müller says, "Nursery tales are generally the last things to be adopted by one nation from another." Another theory, supported by Tylor and Lang, traces the origin of folk-lore to a far earlier source than the Aryan,— the customs and practices of early man: such as totemism, descent from animals or things, which were at last worshipped; and curious taboos or prohibitions, which can be explained by similar savage customs of the present. But late authorities declare that it is useless to seek any common origin of folk-tales; since the incidents, which are few, and the persons, who are types, are based on ideas that might occur to uncivilized races anywhere.

Our popular fairy-tales, or *contes,* have been, in the main, handed down orally. However, some of their elements or variants at least have come down through ancient Oriental literature. The 'Syntipas,' a Greek version, belongs to the 11th century. Then followed translations into several European languages. The earliest collection of European tales was made by Straparola, who published at Venice in 1550 his 'Notti Piacevola,' which was translated into French, and was probably the origin of the 'Contes des Fées.' The best early collection is Basile's, the 'Pentamerone,' published at Naples in 1637. In 1696 there appeared in the 'Recueil' a magazine published by Moetjens at The Hague, the story 'La Belle au Bois Dormant' (our 'Sleeping Beauty'), by Charles Perrault; and in 1697 appeared seven others: 'Little Red Riding Hood'; 'Bluebeard'; 'Puss in Boots'; 'The Fairy); 'Cinderella'; 'Riquet of the Tuft'; and 'Hop o' My Thumb.' These were published in 1697 under the title 'Contes du Temps Passé Avec des Moralités,' by P. Darmancour, Perrault's son, for whom he wrote them down from a nurse's stories. Within this century the investigations of Jacob and William Grimm, and their successors in this field, have reduced to written form the tales of nearly all nations. We must include in the comparison of stories the Greek myths; as the Odyssey is now conceded to be a mass of popular tales. To these we must add the tales of ancient Egypt; those narrated by Herodotus, and other travelers and historians; the beautiful story of 'Cupid and Psyche,' given by Apuleius in his 'Metamorphoses' of the 2d century A.D., which also was taken from a popular myth. See BEAUTY AND THE BEAST; BLUEBEARD; CINDERELLA; ELVES; FAIRY; FOLK-LORE, etc.

Faith, in Christian theology, a term used in conformity with its New Testament signification, to express ordinary belief or conviction, based upon reasonable evidence; also signifying confidence or trust in God, in Christ, and in the objects, seen or unseen, of religious regard. It likewise means the whole body of beliefs held by the Christian Church; hence, the Christian religion itself.

As understood by Roman Catholic divines, and as defined in the Catechism of the Council of Trent, faith is "that profound conviction of the mind by which we give firm and unhesitating assent to God when he reveals his mysterious truths"; or, in the words of John Henry Newman, it is "belief in certain doctrines because God has revealed them." In the Roman Catholic system dogmas are a fundamental part of the Christian religion, no less essential than piety, love, and obedience: "Religion," says Newman ('Grammar of Assent,' chap. V.), "cannot maintain its ground without theology"; hence that "war-song of faith," the Athanasian Creed, is to the Catholic believer "a psalm or hymn of praise, of confession, and of profound, self-prostrating homage, parallel to the canticles of the elect in the Apocalypse." The Roman Catholic Church requires from all the faithful that they accept as of faith all the dogmatic canons of ecumenical councils and all the dogmatic definitions of Popes; but to accept these with "implicit" faith suffices. This faith is professed when one professes *ex animo* his belief in the one Holy Roman Catholic and Apostolic Church.

In the Protestant interpretation of faith, great emphasis is laid upon the willing surrender of the believer to the requirements of Christianity as understood by the various sects. The will itself is the chief organ of saving faith, through the action of which, in accepting the terms of salvation, the individual is brought into a state of forgiveness, justification (q.v.), and peace in his relations with God, with Christ, and with the spiritual world. The operations of the Holy Spirit are an incalculable factor with the individual, but can avail for salvation through the act of faith only with complete assent of his own will and all his being.

Faith-cure, the practice of curing or attempting to cure disease by appealing to the patient's faith, whether specifically religious in its nature or not; also any cure effected or supposed to have been effected by such means. (See CHRISTIAN SCIENCE; HYPNOTISM; SUGGESTION; THERAPEUTICS.) Questions concerning the legal status of practitioners of faith-cure under one or another name — sometimes "divine healing," "faith-healing," "mental science," "prayer-cure," etc.— have in recent years arisen in different States, but thus far no final determination of them has been reached. In view of present phases of these questions, in this and other countries, the following abstract of an opinion handed down 13 Oct. 1903 by the New York State Court of Appeals has a timely interest, especially as dealing with what many regard as a test case.

In 1901 a citizen of the State of New York, a member of the Christian Catholic Church, organized by John Alexander Dowie (q.v.), with which avoidance of drugs is a cardinal principle, was found guilty in a court of that State of violating the Penal Code by omitting to perform a duty imposed by the law — the furnishing of medical attendance for his sick child, who died of her illness. He was fined $500. The judgment was reversed by the Appellate Division, and the state appealed. In the opinion handed down by the Court of Appeals, affirming the verdict of the trial court, the main points presented are as follows:

After the adoption of Christianity by Rome and the conversion of the greater part of Europe, there commenced a growth of legends of miracles connected with the lives of great men who became benefactors of humanity. The great majority of miracles recorded had reference to the healing of the sick through divine intervention, and so extensively was this belief rooted in the minds of the people that for 1,000 years or more it was considered dishonorable to practise physic or surgery. At the Lateran Council of the Church, held at the beginning of the 13th century, physicians were forbidden, under pain of expulsion from the Church, to undertake medical treatment without calling in a priest; and as late as 250 years thereafter Pope Pius V. renewed the command of Pope Innocent by enforcing the penalties. The curing by miracles, or by interposition of divine power, continued throughout Christian Europe during the entire period of the Middle Ages, and was the mode of treating sickness recognized by the Church. This power to heal was not confined to the Catholics alone, but was also in later years invoked by Protestants and by rulers.

With the commencement of the 18th century a number of important discoveries were made in medicine and surgery, which effected a great change in public sentiment, and these have been followed by numerous discoveries of specifics in drugs and compounds. These discoveries have resulted in the establishment of schools and colleges throughout the civilized world for the special education of those who have chosen the practice of medicine for their profession. These schools and colleges have gone a long way in establishing medicine as a science, and as such it has come to be recognized in the law of our land. By the middle of the 18th century the custom of calling upon practitioners of medicine in case of serious illness had become quite general in England, France and Germany, and indeed, to a considerable extent throughout Europe and in this country. From that time the practice among the people of engaging physicians has continued to increase until it has come to be regarded as a duty devolving upon persons having the care of others to call upon medical assistance in case of serious illness.

Formerly no license or certificate was required of a person who undertook the practice of medicine. A certificate or diploma of an incorporated medical college was looked upon by the public as furnishing the necessary qualification. The result was that many persons engaged in the practice of medicine who had acquired no scientific knowledge with reference to the character of diseases or of the ingredients of drugs that they administered, some of whom imposed upon the public by purchasing diplomas from fraudulent concerns and advertising them as real. This resulted in the adoption of several statutes upon the subject. The provision of the Penal Code [of New York State] under consideration was first adopted in 1881, following the statute of 1880 prohibiting the practice of medicine by other than a physician duly qualified in accordance with the provisions of the act. This, we think, is significant. The legislature first limits the right to practice medicine to those who have been licensed and registered, or have received a diploma from some incorporated college conferring upon them the degree of doctor of medicine; and then the following year it enacts the provision of the Penal Code under consideration, in which it requires the procurement of medical attendance under the circumstances to which we have called attention.

We think, therefore, that the medical attendance required by the Code is the authorized medical attendance prescribed by the statute, and this view is strengthened from the fact that the third subdivision of this section of the Code requires nurses to report certain conditions

FALCONS.

1. Goshawk 2. Marsh Hawk. 3. Pigeon Hawk or Merlin.
4. Fish Hawk. 5. Saker Falcon.

of infants under two weeks of age "to a legally qualified practitioner of medicine of the city, town or place where such child is being cared for," thus particularly specifying the kind of practitioner recognized by the statute as a medical attendant.

The peace and safety of the State involves the protection of the lives and health of its children, as well as the obedience of its laws. Full and free enjoyment of religious profession and worship is guaranteed, but acts which are not worship are not. Children when born into the world are utterly helpless, having neither the power to care for, protect nor maintain themselves. They are exposed to all the ills to which flesh is heir, and require careful nursing, and at times when danger is present the help of an experienced physician. But the law of nature, as well as the common law, devolves upon the parents the duty of caring for their young in sickness and in health, and of doing whatever may be necessary for their care, maintenance and preservation, including medical attendance if necessary, and an omission to do this is a public wrong which the State, under its police powers, may prevent.

We are aware that there are people who believe that the divine power may be invoked to heal the sick, and that faith is all that is required. There are others who believe that the Creator has supplied the earth, nature's storehouse, with everything that man may want for his support and maintenance, including the restoration and preservation of his health, and that he is left to work out his own salvation, under fixed natural laws. There are still others who believe that Christianity and science go hand in hand, both proceeding from the Creator; that science is but the agent of the Almighty, through which he accomplishes results; and that both science and divine power may be invoked together to restore diseased and suffering humanity. But, sitting as a court of law for the purpose of construing and determining the meaning of statutes, we have nothing to do with these variances in religious beliefs, and have no power to determine which is correct.

We place no limitations upon the power of the mind over the body, the power of faith to dispel disease, or the power of the Supreme Being to heal the sick. We merely declare the law as given us by the legislature. We have considered the legal proposition raised by the record, and have found no error on the part of the trial court that called for a reversal.

Faithful Shepherdess, The, a pastoral drama by John Fletcher, published in 1609, and ranking with 'Comus,' which it partly inspired, as one of the finest specimens of this Italian form of poetry extant in English literature.

Faithfull, Emily, English philanthropist: b. Headley, Surrey, 1835; d. 31 May 1895. Out of pure philanthropy, she founded the Victoria *Press,* 1860, in which women alone were employed as operatives. Queen Victoria encouraged her by appointing her "publisher-in-ordinary to the queen." She started the 'Victoria Magazine' as an advocate of women's right to lucrative employment, and appeared in the United States as a lecturer in 1872–82. She was the author of 'Change Upon Change,' a novel (1868); 'Three Visits to America' (1884).

Falcon, a term broadly given to any of many birds of the family Falconidæ (q.v.), but more narrowly to the species of the typical subfamily Falconinæ, whence are derived most of the hawks used in falconry. The falcons proper for strength, symmetry and powers of flight, are the most perfectly developed of the feathered race. They are distinguished by having the beak hooked at the point, the upper mandible with a notch or tooth on its cutting edge. The wings are long and powerful, the second feather rather the longest; legs short and strong. The largest falcons are the three great arctic ones represented by the circumpolar jerfalcon (*Hierofalco, gyrfalco*), and its congeners the Greenland, Iceland and Labrador falcons (see JERFALCON). The type of its race, however, is the noble peregrine (*Falco peregrinus*), to the female of which the term "falcon" was alone given by falconers, and was most highly esteemed for the fierceness, dash and perfection with which she worked. The female is about 17 inches long and 3½ feet in extent of wing; the male is 2 or 3 inches less. The head, neck, a patch under the eye and the whole upper surface are dusky, with gray and brownish shades; the throat and under parts whitish or cream-colored, with dusky bars and arrowheads; legs and feet yellow, bill bluish. It chiefly inhabits wild districts, and preys on grouse, ducks, ptarmigans, pigeons, rabbits, seafowl, etc., pouncing upon them from above with terrific swiftness and force, and always betraying the greatest courage in its encounters with rivals or in defense of its nest, which is usually placed on a ledge of some lofty cliff. This species is to be found in nearly all quarters of the globe, for the North American duck-hawk (variety *anatum*) and certain tropical forms are only sub-species.

Other American true falcons are the pigeon-hawk, sparrow-hawk (qq.v.), and some closely allied western and northern forms. Many of the Old World falcons are famous, and are elsewhere individually described, such as the European hobby, kestrel, merlin, and lanner; the Asiatic shaheen, saker, luggur, turumti and other species trained by eastern falconers; the Australasian quail-hawk, and the large African genus Baza, which has the peculiarity of possessing two "teeth" on the edge of the beak. Another interesting genus is Microhierax, containing the finch-falcons (q.v.). Falcons attain to a great age. One is said to have been found in France, about 1790, with a collar of gold dated 1610, showing it to have belonged to James I. of England.

Falconer, fâk'nėr or fâ'kon-ėr, **Hugh,** Scottish botanist and palæontologist: b. Forres, Morayshire, 29 Feb. 1808; d. London 31 Jan. 1865. He was appointed assistant surgeon on the Bengal establishment of the East India Company. Arriving in India (1830) he examined and reported on a collection of fossil bones from Ava, and won scientific standing in India. In 1832 he was made superintendent of the botanic garden at Saharanpur. He discovered the geological character of the Sewalik Hills, and in order to study their ossiferous deposits he compared them with skeletons of extant species. For these researches he received the Wollaston medal of the Geological Society of England.

Falconer, William, English poet: b. Edinburgh, Scotland, 11 Feb. 1732; d. at sea off Mozambique 1769. Having early shipped before the mast, he became before 1750 second mate of a ship trading to the Levant. The experience of a shipwreck off Cape Colonna, Greece, furnished material for the poem of 'The Shipwreck' (1762), by which he is best known. He was later appointed purser of the frigate Aurora, royal navy, bound for India. The Aurora touched at the Cape of Good Hope in December 1869 and was shortly after lost with all hands. Falconer's 'Poetical Works,' with a biography by Gilfillan, appeared in 1854.

Falconet, Etienne Maurice, ā-tē en mō-rēs făl-cō-nā, French sculptor: b. Vevay, Switzerland, 1716; d. Paris 4 Jan. 1791. Catharine II. of Russia patronized him, and he was employed by her to execute the colossal statue of Peter the Great, erected at Petersburg.

Falconidæ, a family of raptorial birds, comprising the sub-families *Gypaetinæ* (lammergeiers), *Polyborinæ* (carrion-hawks), *Accipitrinæ* (hawks), *Buteoninæ* (buzzards), *Aquillinæ* (eagles), and *Falconinæ* (falcons). They are all remarkable for strong and sharply hooked bills, with a distinct cere, usually fleshy; and most of them have sharp and powerful talons, designed to seize, kill, and tear to pieces the living prey upon which most of them subsist. In the eagles and falcons these characters are developed in the highest degree. The tarsus is usually more or less feathered, in some cases down to the very toes, which are arranged three in front and one behind, and are exceedingly strong and tenacious. There is a projection over the eyebrows except in the ospreys, which gives an appearance to the eyes of being very deeply set in the orbits. These birds range in size from the mighty lammergeier to the falconets, hardly bigger than sparrows. The female is usually decidedly larger than the male, and upon her falls the burden of the support of the young. The tribe is represented in all climates, even to the remote north, but is most numerous in the tropics, while some species are nearly cosmopolitan. Many migrate, but few show any tendency toward flocking. The color of the plumage frequently differs much in the young from that of the full-grown birds, and as their first plumage is retained for some time, this has caused more species to be enumerated than really exist. Plain tints rule, but white and black are often strikingly displayed, and a few species present a considerable variety of colors. Their voice is limited as a rule to screaming cries, but a few utter somewhat melodious notes. The nests of all are rude structures, placed in trees, on rock-cliffs, on the ground, or in some hole. The eggs are few in number — one to five as a rule — and are laid much earlier in the year than is the case with birds generally; and they and the young are well cared for and ably defended by the parents. The sport of falconry (q.v.) took its name from employing certain of these birds in the chase.

Falconio Diomede, apostolic delegate to the United States: b. Pescocostanzo, Italy, 20 Sept. 1842. He entered the Franciscan Order 2 Sept. 1860, and upon completing his studies came to the United States as a missionary, reaching Allegany, N. Y., December 1865, and being ordained priest by Bishop Timon of Buffalo, 4 Jan. 1866. In 1868 he was named president of the College and Seminary of Saint Bonaventure, Allegany, N. Y., and on 29 Nov. 1871, was sent by his superiors to Harbor-Grace, Newfoundland, at the request of the bishop of that diocese, who appointed Father Falconio his secretary and chancellor and rector of the cathedral. In 1882 he came back to the United States, where he remained a year. Returning to Italy in 1883, he was elected Provincial of the Franciscans in the Abruzzi, and in 1889 he was chosen procurator-general and later visitor-general in various provinces. He was preconized bishop of Lacedonia 11 July 1892, and on the 17th of that month was consecrated at Rome by Cardinal Monaco La Valletta. On 2 Feb. 1893, Mgr. Falconio assumed charge of his diocese. He was elevated to the United Archiepiscopal See of Accerenza and Matera in Basilicata, 29 Nov. 1895, but was called thence by Leo. XIII., 3 Aug. 1899, and appointed first apostolic delegate to Canada, taking possession at Quebec, 1 Oct. 1899. On 30 Sept. 1902, he was nominated apostolic delegate to the United States and assumed possession at Washington, D. C., 21 November of the same year.

Falconry, or **Hawking,** the employment of falcons in the chase. This sport is of Oriental origin, and has been practised in the East since before the days of any record,— in China at least 2,000 years before Christ; and it was probably followed at that date all over Asia and down into the Nile valley, for falconers with their hawks are depicted in some of the oldest Egyptian mural paintings. The sport spread over Europe with the Roman domination, but seems not to have been introduced into England until the 9th century. Many laws and social customs regulated this pursuit in Great Britain, and many terms and phrases remain in the language as an inheritance from the art and etiquette of this most elegant form of the chase. Thus the square frame on which hawks were carried to the field was named a "cadge," and the servant who bore it a "cadger"; and a "cast" of hawks meant two taken on a chase together. To "man a hawk" was to tame it; and one so thoroughly trained as to be flown with young ones to show them how to work was called a "make hawk." A hawk was said to "mew," when molting; and to "plume" when she pulls off feathers. A female of any species, but especially of the peregrine, is a "falcon"; a male a "tiercel"; one caught wild a "haggard" or "passage hawk"; one reared from the nest an "eyas," and a young one is a "red hawk"; while a falcon's nest is an "eyry." All the actions of a hawk in its work are named. A hawk "stoops" when she descends upon the "quarry" (prey) with closed wings, to kill it by a stroke of the beak; she "binds" when she seizes large prey in the air and clings to it in its fall, or "trusses" when the prey is of small size. A hawk is said to "clutch" when (as do short-winged hawks) she seizes it in her feet; to "carry," when she tries to fly away with the prey; to "check" when she flies at a bird other than the one intended for her; to "foot well" when she kills successfully; to "make her point" when she rises and hovers over some quarry which has escaped to cover, as in a thick hedge; to "ring" when she rises spirally in the air; to "take the air" when she tries to get above the fleeing quarry; to "wait on" when she hovers above her master at a certain "pitch" (height), waiting for quarry to be flushed. "Seeling" is closing the eyes with a fine thread (no longer done); "imping," mending broken feathers; "mantling," stretching out the wings or one wing and a leg; and "jarak" means keen, or in good condition for work.

The extensive agricultural changes which occurred in England during the 17th century, causing the enclosure and improvement of waste lands; the growth of towns and industry; the altered temper of the people preceding and during the Protectorate; and most of all the introduction of firearms, followed by the sports of shooting and the consequent preserving of game,— all tended toward the decline of falconry, both in England and on the Continent; and game-keepers and peasants began to shoot as "vermin" the grand and valuable birds upon which their forefathers had doted. Nevertheless the sport is still followed by fanciers who keep alive its traditions.

The hawks used in falconry are all true falcons, and nearly or quite the whole list have at some time or place been regularly trained, except in the United States, although here the best of material exists, in our duck-hawk (the peregrine), pigeon, and sparrow-hawks, southwestern prairie-falcon and others. A few clubs here and there have flown their hawks, but the sport shows little sign of becoming general in North America. It is more frequent in Central and South America. In North Africa and the Orient the sport flourishes as much as formerly; and there eagles are often employed, and quarry as large as gazelles and bustards is struck down.

Falconers divide their birds into «long-winged» or «dark-eyed» hawks, and «short-winged» or «yellow-eyed» hawks. The first class contains the true falcons, of which the great jerfalcon (q.v.) was in old times reserved for royalty, the peregrine for an earl, and the others for the nobility; hence these were known as "noble," while the goshawk, kestrel, etc., on account of the inferiority of their masters as well as of their own powers, were styled "ignoble."

Hawks are taken for training either as nestlings or when full-grown. They are trained by being hooded, made to wear bands of leather («jesses») about the legs, to which are attached "varvels" (rings, sometimes carrying bells hung by «bewits»), and a swiveled "leash"; and gradually are accustomed, at first in complete darkness, to being fed and handled, and later to feeding in the light and among spectators, and finally to take first live birds thrown toward it and finally wild quarry. During this process young birds are much at liberty and are then said to be "flying at hack."

The sport was one in which women as well as men of all classes might indulge, going afield on foot and alone, or in mounted cavalcades, and often during mediæval times with royal pomp. The hawks, hooded, were carried by servants on frames suspended from their shoulders, but each sportsman was likely to hold a favorite bird upon his gauntleted wrist — in Europe on the left wrist, in the Orient on the right. Dogs, especially small greyhounds and pointers, were likely to accompany the falconer and were put to use in flushing birds, starting hares and the like. When the hunting scene was reached the hawks were prepared for flight, and some were freed to «wait on» until quarry was sighted; but others, trained differently, were kept hooded until the falconer himself started or perceived the game, when they were unhooded and sent after it. The sportsmen then followed, watched the chase, and recovered prey and hawk as well as they could. Good falcons show a keen interest and great intelligence in their work.

Many books describe both the sport and the falcons in great detail. One of the best of the early works is ‘The Booke of Faulconrie or Hawking,’ by Turberville (1575). Recent British authors of repute are Brodrick, Salvin, Freeman (‘Practical Falconry,’ 1869), and J. E. Harting (‘Hints on the Management of Hawks,’ 1884). The latest general work is ‘Coursing and Falconry,’ by Cox & Lascelles, in the Badminton Library, 1892.

Faldstool, or Foldstool, the name of various pieces of English church furniture, the principal being a portable folding seat, also called faldistory, similar to a camp-stool used by a bishop when officiating in other than his own cathedral church; and a small desk at which the litany is read, the name dating from a period when folding lecterns were used.

Falerii. See FALISCI.

Falernian Wine, one of the favorite wines of the Romans, so called from *Falernus Ager* (the Falernian Field), the district in which it was grown, in Campania, Italy. It is described by Horace as, in his time, surpassing all other wines then in repute. In the time of Pliny, however, as he himself informs us, Falernian wine had already, owing to a want of care in its cultivation, begun to decline in quality. See WINE.

Falguière, Jean Alexandre Joseph, zhŏṅ ä-lex-zäṅdr făl-gyăr, French sculptor and figure painter: b. Toulouse, France, 7 Sept. 1831. Both in sculpture and painting his work is of very notable excellence, and displays originality and vigor. The Luxembourg Gallery in Paris contains his sculptures: ‘Christian Martyr’ (1868); and ‘Victor in the Cock Fight’ (1870). Among his most noted paintings are: ‘The Wrestlers’ (1874); ‘Susanna’; and ‘Slaughter of a Bull’ (1881).

Falieri, Marino, mä-rē'nō fä-lē-ā'rē, Doge of Venice: b. 1278; d. Venice 17 April 1355. He commanded the troops of the republic at the siege of Zara in Dalmatia. He there gained a brilliant victory over the king of Hungary, and was afterward ambassador to Genoa and Rome. He was elected doge of Venice on 11 Sept. 1354, but in the following year dissatisfaction with the light punishment imposed upon a noble who had insulted Falieri's young wife caused him to conspire with the lower orders to overthrow th republic and make himself sovereign of the state. His plot was discovered on the night before it was to have been consummated, and he was beheaded 17 April 1355. The last scenes of his life are depicted in Byron's tragedy of ‘Marino Falieri.’ Plays have been written on the same subject by Casimir Delavigne and Swinburne.

Falisci, fȧ-lis'ī, a people of Etruria, said to have been originally a Macedonian colony. They occupied Falerii, one of the 12 Etruscan cities. When they were besieged by the Roman general Camillus, a schoolmaster offered to betray his pupils into the hands of the enemy, that, by such a possession, he might easily oblige the place to surrender. Camillus heard the proposal with indignation, and ordered the man whipped back to the town by the very pupils whom his perfidy would have betrayed. This instance of magnanimity operated upon the people so powerfully that they surrendered to the Romans.

Falk, Paul Ludwig Adalbert, powl lood'vĭH ä'däl-bĕrt fälk, Prussian statesman: b. Metschkau, Silesia, 10 Aug. 1827; d. 7 July 1900. He was appointed minister of public worship and education in 1872, and in this capacity was mainly instrumental in carrying the so-called May laws (because passed in May 1873–4–5), aimed at the restriction of the Roman Catholic

Church in Germany, by limiting the influence of the clergy in the schools, by reorganizing the seminaries for the training of teachers, and by defining in a stricter and more comprehensive manner the relations generally of the clergy to the state. When, however, Bismarck came to bid for the support of the clerical party, in order to carry out his later internal policy, Falk was compelled to resign.

Falk, fälk, **Johannes Daniel,** German author: b. Dantzic, Prussia, 28 Oct. 1768; d. 14 Feb. 1826. His capacity for satire was considerable. Among his works are: ‘A Pocket Book for Friends of Jest and Satire’ (1797); ‘Men and Heroes’ (1796), a satire in verse, and ‘Prometheus’ (1804), a dramatic poem.

Falke, Jacob von, yä'cōp fon fäl'kĕ, German connoisseur and historian of taste: b. Ratzeburg 21 June 1825. His administrative capacity has placed many art galleries and repositories of art treasures in Germany and Austria upon a successful basis. His writings, particularly ‘Knightly Society in the Days of Homage to Womanhood’ (1862); ‘History of Modern Taste’ (1866); ‘Art and Art Study’ (1878); ‘Hellas and Rome’ (1879); and ‘History of Taste in the Middle Ages’ (1893), are notable for both learning and judgment.

Falkirk, fâl'kėrk, **Battle of,** a contest in which Edward I. of England gained a victory over Wallace 22 July 1298. The king's army is said to have contained 7,000 to 8,000 mounted men and 80,000 footmen. Wallace's force amounted to about a third of the English army. His infantry was drawn up in circles, the men in the outer ring kneeling and holding their lances obliquely. The archers occupied the centre of the circles. The overwhelming superiority of the enemy's horse, however, decided the battle. Wallace retired with a small body to Stirling, but the bulk of his army was broken up and destroyed. See WALLACE, SIR WILLIAM.

Falkland, fâk'land, **Lucius Cary,** VISCOUNT, English statesman and soldier: b. probably at Burford, Oxfordshire, 1610; d. Newbury 20 Sept. 1643. In 1633 he succeeded his father in the peerage, and for some years after chiefly resided at his seat of Burford, which he made a kind of academy of learned men, being continually surrounded by the scholars from the neighboring universities, and visitors from London. Here it was that Chillingworth composed his famous work against «Popery»; and questions of morals, theology, and literature were discussed in a congenial circle with the utmost freedom. In 1640 he was chosen member of the House of Commons for Newport, Isle of Wight. At first he warmly supported the Parliament party, but a strong attachment, however, to established forms, and some doubts of the ultimate objects of the parliamentary leaders, caused him to retract, and he embraced the party of the king when hostilities commenced, and attended him at the battle of Edgehill and the siege of Gloucester. At the battle of Newbury he was struck from his horse by a musket-shot, and was found the next day dead upon the field.

Falkland Isles, two large islands, with a number of smaller ones surrounding them, in the South Atlantic Ocean; about 300 miles east of the Strait of Magellan. Area, 7,510 square miles. The soil is light, and but scanty crops are obtained. Sheep raising is the principal occupation. The capital is Stanley. These islands were discovered by Davis in 1592, and came into the possession of the British in 1771. Their appropriation has been at times disputed; but since 1833 the British have held uninterrupted occupancy of them. Pop. (1901) 2,043.

Falkner, fäk'nėr, **Roland Post,** American statistician: b. Bridgeport, Conn., 14 April 1866. He was graduated at the University of Pennsylvania in 1885; studied economics at Berlin, Leipsic, and Halle-on-Saale, Germany; was instructor in accounting and statistics in the University of Pennsylvania in 1888–91, and professor of statistics in 1891–1900. He served also as statistician of the United States Senate Committee of Finance in 1891; as secretary of the United States delegation to the International Monetary Conference; and as secretary of the conference in 1892. He is author of numerous essays on criminology, sociology, etc.; chief of the division of documents in the Library of Congress, and editor of ‘Annals’ of the American Academy of Political and Social Science.

Fall Army Worm, the caterpillar of a gregarious moth (*Laphygma frugiperda*). See GRASS-WORM.

Fall-fish, or **Silver Chub,** a cyprinodont fish, or «minnow» (*Semnotilus corporalis*) of the eastern United States. It is very common east of the Alleghanies in clear, swift streams and rocky pools, and reaches 18 inches in length. It is steel blue above, sides and belly silvery, but in the breeding season the fins and lower surface of the males are rosy. The fins are of moderate size and unspotted.

Fall of Man, a commonly received doctrine of Christianity, founded upon the historical narrative contained in the third chapter of the book of Genesis, together with the allusions to the same matter in other parts of Scripture. The history of the fall, as given in Genesis, contains the following particulars: God having placed Adam and Eve in the garden of Eden, and forbidden them under pain of death to eat of the fruit of the tree of the knowledge of good and evil, Eve, tempted by the serpent, first ate of the fruit herself, and afterward gave of it to her husband, who followed her example. Both were driven out of Eden. Punitive sentences were passed upon each of them, and upon the serpent, which is alluded to by St. Paul as representing the devil. In the subsequent narrative the consequences of the fall significantly appear. The first man born of the original pair is a murderer, and his descendants grow in wickedness until a flood is sent to carry them away. As might be expected, this most suggestive narrative has given rise to inexhaustible controversy. The opinions on the fall may be divided into three classes: those which reject the narrative altogether; those which accept it as a mythical or allegorical account of the origin of evil; those which regard it as in the main historical. As a mere matter of literary criticism, the uninterrupted flow of the narrative down to times and events evidently historical, together with the uniformity and sobriety of its style, leave little ground for the supposition that the writer himself supposed he was dealing in allegory. The historical view of the fall, besides the theoretical controversies to which it gives rise as to its account of the origin of evil, encounters difficulties from two sources — the modern sciences of chronology and ethnology. In the meantime these remain difficulties only, as these sciences are by no means in a state of sufficient maturity to allow their conclusions to be absolutely applied. It is remarkable that in most mythologies the serpent is worshipped as a beneficent being, though Tylor shows that Aji Dahaka of the Zarathustrians (Zoroastrians), which is a personification of evil, may have an historical connection with the serpent of Eden. With regard to the relation of man's fall to that of Adam, St. Paul says "by one man's disobedience many were made sinners" (Rom. v. 19), and "as by one man sin entered into the world, and death by sin, and so death passed upon all men for that all have sinned" (ver. 12). It seems impossible to reconcile the constant appeals made in Scripture to the moral nature of man with the notion that that nature is inherently and radically corrupt. It would also appear that the statements of Scripture with regard to the actual moral condition of man, strong as they are, do not absolutely require this mode of accounting for them. Without supposing any radical change of man's moral nature, or even any change of it whatsoever, it is only necessary to suppose a change in his relation to God to explain all that is said regarding him. It is supposed that man's moral nature consists of capabilities which are good or bad according as they are directed, and that God himself is the object of all its highest aspirations. The fall being supposed to consist in the alienation of man from God, it is easy to perceive that all these aspirations, being deprived of their proper objects, must apply themselves to improper ones, and become evil in their tendency; hence the sudden rise of pride, selfishness, ambition, and all evil passions. In as far also as man's nature is affected by the hereditary transmission of qualities it might become actually vitiated in its tendencies, and this, together with the accumulation of evil habits, would produce those climaxes of violence or corruption which have from time to time convulsed or disintegrated society, which have called forth the denunciations of prophets, and by their very excesses have produced a reaction, which, however, has left human nature as incompetent to guide itself as ever, and ready, after a period of repose, to progress toward another crisis. The fall, according to this view, consists in the moral inadequacy of man's nature when left to itself, and the actual evils flowing from this inadequacy. It is argued by theologians that in the original sentence pronounced on the transgressors there is contained the promise of a redemption, and they maintain that the whole scope of Scripture is directed to the development of this promise, and of the scheme of providence associated with it. It is from the New Testament, however, and not from the Old, that the whole doctrine of the fall has been built up. Milton seized on this as the groundwork of his two great poems. See ADAM; ORIGINAL SIN.

Fall Poison, the name given in the United States to the plant *Amianthium muscætoxicum,* so called because cattle feeding on its foliage in the fall of the year are poisoned.

Fall River, Mass., city, port of entry, in Bristol County; on Mount Hope Bay at the mouth of the Taunton River; on the New York, N. H. & H. R.R.; 49 miles south of Boston. It is connected with New York by the Fall River line of steamers, with Philadelphia by the Windsor freight line, and with New England seaports by passenger and freight lines of steamers. The area of the city is 41 square miles, and it is 200 feet above sea-level. It has a good harbor, sufficiently commodious for the largest steamers, and excellent water power, as the Fall River, the outlet of Watuppa Lake, has a fall of 129 feet in less than half a mile. The water for city uses comes from Lake Watuppa, and the waterworks plant is owned by the municipality. The streets are well laid out; many of the buildings are constructed of the granite which is found in the vicinity. It has excellent public and parish schools, notably the B. M. C. Durfee public high school and the Academy La Ste. Union des Sacrés Cœurs; good circulating libraries, a State armory, over half a hundred churches and chapels, daily and weekly newspapers, and electric street railway connections with neighboring cities and towns.

Fall River is the largest cotton-milling city in the United States. According to the Federal census of 1900 the city had 785 manufacturing establishments, employing $58,549,934 capital, and 32,780 persons; paying $11,739,129 for wages, and $19,789,859 for materials; and having a combined output valued at $43,071,530. The cotton industry, 42 establishments, with $45,641,084 capital, and a combined output valued at $29,097,667. Next in value of output was the dyeing and finishing of textiles ($2,995,979). Other important manufactures were foundry and machine shop products ($932,873); bakery products ($555,267). In 1901 there were 7 national banks with $2,150,000 capital and $1,193,779 surplus and several savings and co-operative banks. The exchanges at the United States clearing-house during the year ending 30 Sept. 1901, aggregated $45,369,554.

The city was originally a part of Freetown, but was incorporated separately in 1803. Later it was called Troy, but its first name was restored in 1834. The city charter was granted in 1854, and in 1862 Fall River in Newport County, R. I., was annexed. Pop. (1905), 105,762. JOHN H. ABBOTT.

Fall Trank, a drink once reputed to cure the effects of falls; a vulnerary made from several aromatic and slightly astringent plants which grow chiefly on the Swiss Alps; hence the name *Vulneraire Suisse,* given to such dried plants cut into fragments. Within the 19th century, in England, a kind of vulnerary known as black beer was often prescribed in country practice for inward bruises.

Fall Webworm. See WEBWORM.

Fallacy, in logic, an argument used as decisive of a particular issue, which in reality it does not decide. Fallacies are variously classified by different logicians. A fallacy may either exist in the substance or in the form of the argument. If it exists in the substance it does not belong to logic, as commonly understood, to expose it; but logicians differ as to what constitutes the proper distinction between form and substance. J. S. Mill in particular extends the sphere of logic in respect to the treatment of fallacies beyond what has been usually assigned to it.

Fallen Timbers, Battle of, 20 Aug. 1794; on the Maumee River, about 15 miles from Toledo, Ohio. The Indians had about 2,000 warriors, with 70 white rangers, French, English, and renegade Americans; they were in a line some two miles long at right angles to the river, behind a forest blown down by a hurricane. Wayne had some 3,000 men; 2,000 regulars, and 1,000 mounted volunteers from Kentucky, under Charles Scott, who were thrown to the left to turn the Indians' flank. The Indians began the attack and drove in the advance volunteers; then Wayne sent his regular cavalry to repel them, while his first line of infantry advanced with trailed arms, firing at close range and then charging with the bayonet. Both attacks were entirely successful. Less than 1,000 of the Americans were engaged. They chased the Indians up to the British fort some miles away. Their total loss was 33 killed and 100 wounded, the Indians and British probably losing two or three times as many killed. Eight Wyandot chiefs were slain. This defeat, the greatest ever suffered by the northwestern Indians, led to the treaty of Greeneville (q.v.).

Fallet, Nicholas, French author: b. Langres in the department of Haute-Marne, France, 1753; d. Paris 22 Dec. 1801. He was the son of a hatter, and was destined for the bar; but irresistibly drawn toward literature he removed to Paris, where he became a contributor to the ‹Gazette de France,› the ‹Journal de Paris,› and the ‹Dictionnaire Universel.› Chief among his works are the tragedies ‹Barnevelt› (1775) and ‹Tibère› (1783); the comic opera ‹Matthieu› (1783), ‹Les Fausses Nouvelles,› a comedy, and two collections of poems, ‹Mes Prémices› (1773), and ‹Mes Bagatelles› (1776).

Fallières, Clément Armand, French politician and statesman: b. Mézin, in the Department of Lot-et-Garonne, 6 Nov. 1841. He studied law, was admitted to the Bar of Nérac, and from 1871–5 was mayor of that city. In 1876, 1877, and 1878 he was elected as a Republican to the Chamber of Deputies, in the latter year being appointed Minister of the Interior, a position which he again occupied in 1882 and 1883. From 1883–5 and again from 1889–90 he was Minister of Public Instruction; in 1887 Minister of the Interior; and in 1887–8 and again from 1890–2 Minister of Justice. In 1890 he was elected Senator, a position which he has held ever since. In 1899, when Loubet became President of the Republic, Fallières succeeded him as President of the Senate, a post to which he was elected in 1900 and on 11 Jan. 1906. On 17 Jan. 1906 the National Assembly elected him President of the Republic to succeed Loubet (q.v.).

Falling Stars. See METEORS.

Fallmerayer, Jacob Philipp, yä'kōp fē'lip fäl'mē-rī-ėr, German author: b. Tschötsch, Austrian Tyrol, 10 Dec. 1790; d. Munich 26 April 1861. As a scholar, especially linguist, and as an explorer of the Orient, his fame is international and his work authoritative. He published: ‹Fragments from the Orient› (1845); ‹History of the Peninsula of Morea in the Middle Ages› (1830), and other important writings.

Fallopian Tubes, two ducts or canals about five inches long and one third of an inch in diameter, attached to the upper corners of the uterus. Within they are lined by a mucous membrane continuous with that of the uterine cavity, but differing in having cilia. Outside of the mucous membrane there is a thin layer of muscle-tissue. The outermost layer is from the peritoneum, in large part a fold of the "broad ligament." At the free end the tube flares out into fimbriæ, thus exposing a large surface to catch the ova given off from the surface of the adjacent ovary. Aided by the waving cilia, an ovum passes down this tube to the uterine cavity, there to undergo development or to be extruded with menstrual blood. Spermatozoa can pass up the Fallopian tubes and impregnate an ovum within the lumen. Development then becomes possible, giving rise to tubal pregnancy or ectopic gestation.

Fallopio, Gabriele, gä-brē-ä'lē fäl-lop'pē-ō (usually known as FALLOPIUS), Italian anatomist: b. Modena 1523; d. 9 Oct. 1562. He studied at Ferrara and at Padua, at which last place he is said to have attended the lectures of Vesalius. He became professor at Ferrara, whence, in 1548, he removed to Pisa. He continued there three years, and was then made professor of surgery, anatomy, and the materia medica at Padua, where he remained till his death. The principal work of Fallopius is his ‹Observationes Anatomicæ› (1561, 8vo), which, as well as his other writings, has been several times reprinted. He was the first anatomist who accurately described the vessels and bones of the fœtus; and his account of the Fallopian tubes in females has perpetuated his name.

Falloux, Alfred Frédéric Pierre, äl-fred frā-dā-rik pē är fä-loo, French writer: b. Angers, France, 7 May 1811; d. there 7 Jan. 1886. Legitimist and clerical sympathies influenced his career, his typical writings being: ‹Madame Swetchine, her Life and Works› (15th ed. 1884); ‹Story of Louis XVI.› (6th ed. 1881); and ‹Political Speeches and Miscellany› (1882).

Fallow, land which, after being tilled, is left for a season or more without being planted or sown. The Roman system of wheat raising was a rotation of fallow and wheat alternately. Under the Romans Britain exported a great quantity of wheat, and for centuries afterward the same system was followed. The method presupposed a moderately fertile soil, and turned out best where clay was present. The object of fallowing is to liberate fertilizing elements from the mold, admitting air and destroying noxious plants and insects. Improvements in agricultural methods and the multiplication of fertilizing material has caused the abandonment of this resort to fallowing which, however, might in some cases be revived with advantage. For summer fallow the land should be ploughed at the end of May; for winter fallow the land should be ploughed in autumn.

Fallow crops is a term applied to green

manuring crops (see GREEN MANURING), which are of more advantage in moist than in dry climates, where injury is likely to be wrought by autumnal draughts. Bastard fallowing is the Scotch practice of ploughing hay-stubble at the end of summer. It is known in North America as short fallow and is very beneficial.

Fallow-deer, a dun-colored deer (*Dama platyceros*) native in southern Europe, and eastward. It is smaller than the red deer, has palmated antlers, and soft, fine fur. Its color is yellow-brown in summer, shading to white on the ventral surfaces, and its winter coat is darker. It is usually spotted, especially when a fawn. The male is called a buck, the female a doe, the young a fawn. The doe is without horns. The deer is smaller than the stag and has more spreading horns. It goes in herds and each herd has its master, an old buck, which all the others obey. This is a woodland deer, whose flesh supplies one of the choicest varieties of venison. Though native only southward the fallow-deer has been introduced into the parks and game-preserves of northern Europe, whence it has in some instances escaped and returned to a wild state. It has multiplied and flourished, especially in England.

Fallows, Samuel, American Reformed Episcopal bishop: b. Pendleton, Lancashire England, 13 Dec. 1835. He came to America in 1848; was graduated at the University of Wisconsin in 1859; was minister in the Methodist Episcopal Church 1859–75, and later of the Reformed Episcopal Church. He served with distinction in the Civil War; was State superintendent of public instruction in Wisconsin 1871–4; regent of the University of Wisconsin in 1866–74; and president of Wesleyan University in 1874–5. He became rector of St. Paul's Reformed Episcopal Church in Chicago in 1875, and bishop in 1876. He is author of numerous works, including: 'Handbook of Abbreviations and Contractions'; 'Life of Samuel Adams'; 'Students' Biblical Dictionary'; 'Past Noon'; 'Splendid Deeds'; 'Supplemental Dictionary of the English Language,' etc.

Falls City, Neb., city, county-seat of Richardson County; on the Burlington & M., and the M. P. R.R.'s; about 85 miles southeast of Lincoln. Its chief manufactures are flour, canned goods, cigars, foundry products, furniture, and beer. The trade is chiefly in wheat, corn, cattle, and manufactured articles. The electric light and waterworks plants are owned by the city. It has a good public library. Pop. (1900) 3,022.

Falmouth, fal'muth, England, a seaport town in the county of Cornwall, at the mouth of the Fal River, 11 miles from Truro. It has a good harbor, and a fine and spacious roadstead. There are two castles on the coast, one of which, Pendennis, commands the entrance of the harbor; and the other, on the opposite side, is St. Mawes Castle. Its trade consists chiefly in tin, copper, firearms and ammunition, and chemical products. Pop. 11,825.

Falmouth, Ky., city, county-seat of Pendleton County; 32 miles southeast of Cincinnati; on the Licking River, the Louisville & N. R.R. It is in an agricultural region, and its manufactures are woolen goods, flour, lumber, dairy products, and canned goods. Live stock and tobacco are shipped to Covington and Newport on the Ohio River. Pop. (1900) 1,134.

Falmouth, Mass., town in Barnstable County; on Buzzard's Bay, Vineyard Sound, and on the New York, N. H. & H. R.R., at the extreme west end of Cape Cod; 50 miles northwest of Boston. It is the centre of an agricultural and cranberry region. It is best known as containing the Wood's Holl (q.v.) Station of the United States Fish Commission. Pop. (1900) 3,500.

False Bay, an inlet on the coast of Cape Colony, South Africa; circular in form, about 24 miles long, and so well protected from storms as to make it a good shelter harbor. It is a British naval station.

False Cadence, a musical term. When the last chord of a phrase is other than the tonic chord, and is preceded by that of the dominant, the cadence is said to be interrupted, false or deceptive. See CADENCE.

False Chinch-bug. See WHEAT INSECT PESTS.

False Decretals. See DECRETALS, FALSE OR PSEUDO-ISIDORIAN.

False Demetrius, The. See DEMETRIUS.

False Imprisonment, the unlawful detention of a person, whether in a common prison or a private house, or even by forcibly detaining one in the streets or highways. The law punishes false imprisonment as a crime, besides giving reparation to the party injured, through an action in tort.

False Indigo, a common name for some American species of the genus *Amorpha,* of the pea family. The most widely known plant called by this name is *A. fruticosa,* a shrub growing from 5 to 20 feet in height, along streams in Ohio, Minnesota and Manitoba, south to Florida, Colorado and Mexico. When found in the Middle States, it is an escape from cultivation, its spike of purple flowers making an exceedingly ornamental shrub.

False Personation, for the purpose of obtaining property of others, was formerly a misdemeanor punishable by a fine or imprisonment, but is now made penal by special statute. The penalties for personation are frequently heavy. Thus to personate the owner of any share, stock, or annuity, etc., is felony, and liable to a term of imprisonment. The false personation of voters at an election is a misdemeanor punishable with imprisonment.

False Point, a cape and harbor of Bengal, 43 miles east of Cuttack. The harbor, with its large lighthouse on the cape, is safe and capacious, and is considered the best between Calcutta and Bombay; it is the entrepôt for the trade of Orissa, and a regular port of call for the British Indian Company's steamers. The name was given because frequently this projection was mistaken for Point Palmyras.

False Pretenses, for the purpose of obtaining property is a misdemeanor at common law, and punishable by fine or imprisonment. Some kinds of it are now punishable by imprisonment not exceeding five years, the statutes, however, varying in different States.

False Scorpion, or **Book Scorpion,** a diminutive spider-like creature of the order

Pseudoscorpionida (see ARACHINDA), allied to the «harvestmen» and «false spiders.» They occur in all the warmer parts of the world, under bark, stones and rubbish, or hidden in deep moss; and one typical species, the «book scorpion» (*Chelifer cancroides*), infests museums, old libraries, and dusty corners generally. Unlike the spiders these have no constricted «waist» separating the abdomen from the foreparts; and like the true scorpions the pedipalps are developed into relatively enormous chelate arms. The book scorpion thus resembles a minute crab. They are slow in their motions, feeling their way along with their pincers; and several blind species inhabit caverns. They have spinning glands, situated in the cephalothorax, but use the silk only for making small protective cells or cases into which they retreat when laying eggs (afterward carried about by the female), or molting, or during hibernation.

False Spider. See SCORPION SPIDER.

False Weights and Measures. See WEIGHTS AND MEASURES.

Falsetto (Ital.), in singing, a term applied to the notes above the natural compass of the voice. It is also called a head or throat voice, in contradistinction to the chest voice, which is the natural one. The falsetto voice is produced by tightening the ligaments of the glottis. Its thin, constrained effect is most noticeable in men with deep-set voices, the register of which it frequently extends more than an octave above the pure chest voice.

Falstaff, fâl'staf, SIR **John,** a character in Shakespeare's dramas, 'Henry IV.,' Parts I. and II.; 'Henry V.,' and 'Merry Wives of Windsor,' conspicuous for lying, cowardice, drunkenness, and boastfulness, yet brimming over with wit and geniality. See FASTOLF, SIR JOHN.

Falster, fäl'stĕr, **Christian,** Danish poet: b. 1 Jan. 1690; d. 24 Oct. 1752. His 'Satires' on his age, modeled on Juvenal, gave him eminent rank among the native poets. He wrote three volumes of 'Philological Amenities or Various Discourses,' containing a mass of highly interesting observations on the affairs of the time.

Falster, one of the Danish islands in the Baltic, separated by narrow straits from Zealand on the north, Moen on the northeast, and Laaland on the west; area, 18 square miles. It is well watered, richly wooded, and so prolific in fruit that it has been called the «Orchard of Denmark.» The chief products are corn, hemp, hops, cattle, honey, and wax. Some shipbuilding is carried on. The capital is Nykjöbing. Pop. (1901) 34,422.

Falun, or **Fahlun,** fä'loon, Sweden, town, capital of the county (län) of Kopparberg; on a stream connecting lakes Varp and Runn; 130 miles northwest of Stockholm. What is now included in the town of Falun was once nine little villages. Many of the buildings date from the 14th century; one, an old church, has a green copper roof. It is the seat of a mining school, and it contains a hospital, gymnasium, and several other public buildings of note. The town owes its prosperity to the copper mines in the vicinity, which have been called the richest in the world. Gold and silver are also mined, but the rich «copper mines of Falun» have given to the town the name of «The Treasury of Sweden.» Pop. (1901) 10,023.

Consult: Nordenström, 'L'Industrie Minière de la Suéde' (1897); Sundbarg, 'La Suéde, son Peuple et son Industrie.'

Faluns, fä-lun̄, a French provincial term for the shelly Tertiary (Upper Miocene) strata of Touraine and the Loire. Though generally composed of shelly sand and marl, in some districts they form a soft building stone, chiefly composed of an aggregate of broken shells, bryozoa, corals, and echinoderms, united by a calcareous cement. They are found in scattered patches of wide extent, but rarely more than 50 feet in thickness; they have long been known and utilized for their fertilizing properties. The fossils are chiefly marine, but there occur also land and fresh-water shells, and the remains of numerous mammals.

Fama, fā'ma, in mythology, the Roman goddess of fame, rumor, reports, news, or tidings of any sort, whether good or evil. A graphic description of this goddess is found in Virgil, who represents her as winged and with as many ears, eyes, and tongues as feathers. She is sometimes pictured with a trumpet, either blowing it or holding it in her hand.

Famagosta, fä-mä-gos'tä, or **Famagusta,** fä-mä-goos'tä (ancient ARSINOE), a seaport on the Island of Cyprus, 40 miles east of Nicosia. Famagosta, during the Venetian régime, was one of the richest and most populous towns in the Levant. The name, Fama Augusta, shows its Roman origin. It is now almost in ruins, with its once fine harbor nearly choked with sand, having declined since its conquest by the Turks in 1571. About five miles northeast are the ruins of Constantia, occupying the site of the ancient Salamis, now called Eski, or Old Famagosta. Guy de Lusignan was here crowned king of Cyprus in 1191. Since Great Britain obtained control of Cyprus, Famagosta has begun to revive in importance. Pop. (1901) 3,825. (See CYPRUS.) Consult: Fyler, 'Development of Cyprus, and Rambles on the Island'; Cesnola, 'Cyprus; its Ancient Cities.'

Familiar Spirit, one of those demons or evil spirits which were supposed to attend and be at the service of a magician or other favored person. The belief in familiar spirits is very ancient, and by the law of Moses such as had familiar spirits were to be put to death. Where Socrates speaks of his attendant demon, he is generally understood to refer to the inner feelings and promptings of his nature, and not to any familiar spirit. In Eastern countries the belief in familiar spirits is very general. Attendant genii in Oriental tales are represented as sometimes good and sometimes evil. The «slave of the lamp» mentioned in the 'Arabian Nights' is a well-known illustration of this superstition. A belief in familiars was widely diffused over Europe in the Middle Ages. Jovius says that Cornelius Agrippa was always accompanied by a devil in the form of a black dog; and Goethe makes Mephistopheles first appear to Faust in this shape. Paracelsus was believed to carry about with him a familiar spirit in the hilt of his sword. See WITCHCRAFT.

Familists, name of a sect which arose in Holland about the middle of the 16th century, and taught that the essence of religion consisted in the feelings of divine love; hence they were otherwise called the Family of Love.

Familistère, fä-mē-lē-stär (Fr.), a community living as one family; a familistery. It is especially used as referring to the community established by Godin (q.v.) in Guise, France. See GUISE.

Family, a category in the classification of animals and of plants, which falls between the narrower «genus» and the broader «group» order. It designates a natural group determined by the common possession of characters of a broader kind than those which determine the limits of a genus, and may be composed of many genera exhibiting the required affinity, or of only a single genus represented by one species. In the former case minor subdivisions may be convenient under the designation *sub-family;* an example of this occurs in *Falconidæ* (q.v.). On the other hand, certain groups of families, forming subdivisions of an order (q.v.), and called *super-families,* are sometimes made. In zoology a group of forms is ranked as a family on considerations of form as expressive of structure. This is sometimes very plain, as in the cat family, or the owl family; but frequently the limits are less easily marked, and the rank remains a subject of dispute pending the decisive results of better information. In zoology the technical name of a family, usually derived from that of its most typical or prominent genus, always ends in *idæ.*

In botany the corresponding category — that is, an assemblage of genera — is more frequently designated a «natural order,» and its taxonomic name always ends in *aceæ.* It is based upon similar appearance and habit of growth and flowering, as the *Ranunculaceæ, Coniferæ.*

Family Compact, the name given to a compact organized by the Duke de Choiseul, first minister of Louis XV., between the various members of the Bourbon family, then sovereigns of France, Spain, the Two Sicilies, Parma, and Piacenza, mutually to guarantee each other's possessions. It was signed 15 Aug. 1761. It entailed on Spain a war with England, then at war with France. Other similar agreements, especially those of 1733 and of 1743 between France and Spain, bear the same name.

Family, Law of. See LAW OF FAMILY.

Famine, a dire want of food affecting considerable numbers of people at the same time. Irregular rainfalls in tropical climates, imperfect methods of irrigation, or, as in Ireland, the too exclusive dependence of the mass of the people on a single article of food which happens to fail, are among the commonest causes of famines. In the early and mediæval ages they were frequent. The year 879 was one of universal suffering from lack of food. The famine of 1125 diminished the population of Germany one half. All through the Middle Ages public opinion upheld the city authorities in driving out of the gates the neediest inhabitants and letting them perish. In a famine which devastated Hungary in 1505 parents who killed and ate their children were not punished. It was after a famine of 1586 that the poor-law in England had its beginning. As late as the middle of the 17th century famines were a common affliction in Europe and even in the 18th century they still occurred. The last time a period of bad harvests was designated as a famine in Germany was in 1817. The rapidity of modern communication and transport has made severe famine almost impossible in western or central Europe or North America. In Ireland, famines more or less serious have at various times prevailed owing to failure of the potato crop. In 1846 the dearth was so great that 10,000,000 sterling were voted by Parliament for relief of the sufferers. India has long been subject to great famines, and the government's budget makes annual provision against such need. Under the rule of the English, the population has greatly increased, and as the majority of people live from hand to mouth in ordinary times, the slightest failure in the rice crop causes the famine point to be immediately reached. In 1769–70 as many as 3,000,000 perished; in 1865–6 about 1,500,000, and in 1877 about 500,000. The authorities grappled very successfully with the famines of 1896–7 and 1899–1900, which extended over large areas, yet there was great loss of life. The recent famine in India cost the government in 1900–1 $28,235,000, of which amount $21,135,000 was expended in direct relief. Apart from this $13,700,000 was advanced to native states for famine relief and $4,735,000 for special agricultural advances. Much help was sent from other countries, including very large contributions from the United States. In 1870–2 Persia lost 1,500,000 inhabitants, a quarter of the whole population. In China over 9,000,000 are said to have perished in 1877–8 from famine. In the northern provinces of Shensi, Shansi, and Honan, with a population of 56,000,000, during the years following 1877 it was reckoned that between 4,000,000 and 6,000,000 people perished, and famine visited the empire in 1903. In the famine of 1891–2 in Russia it was estimated that in 18 provinces 27,000,000 of inhabitants were affected. Although many of the causes of famine are beyond human control, it is probable that the extension of sound agricultural knowledge and the adoption of a more rational system as regards the kinds and quantities of crops grown will in the future render famine almost unknown in most countries.

Famine Fever. See RELAPSING FEVER.

Fan-Cheng, făn-cheng', China, city in the province of Hu-peh; on the Hankiang; 380 miles west of Nanking. It is located on one of the principal trade routes between the northern and southern provinces of China. Pop. 100,000.

Fan Coral, the spreading fan-like growths of corals of the family *Gorgonidæ.* The coral stock is here horny or calcareous and takes a bushy growth, or frequently spreads from its base into a flat network, making a «sea-fan.» In this coral the short calicles of the single retractile polyps stand perpendicularly to the axis, in which run communicating canals. These alcyonarians are numerous not only in the tropics, one beautiful red or yellow species (*Rhipigorgia flabellum*) flourishing along the coast of Florida, but also in the deep cold waters of the North Atlantic.

Fan Cricket, a British name for the mole-cricket.

Fan Palm, a name common to all those palms which have fan-shaped (flabellate) leaves, but more particularly applied to those of the genus *Chamærops,* of which a common species in the Mediterranean region is *C. humilis.* The East Indian «great» fan palms are species of *Corypha,* one of which is the taliput-palm (*C. umbraculifera*), whose leaves furnish the «palm-leaf fans" of commerce. The West Indian fan palm is *Sabal blackburniana.*

Fan-tan, a Chinese word, *fan,* number of times; *tan,* apportion: a gambling game very popular with the Chinese. There are various forms of fan-tan, the simplest and most commonly played is that in which a pile of copper coins, usually cash, is covered with a bowl, the player staking or betting money on what the remainder will be when the pile of coins has been divided by four. As in the American game of poker there is a "kitty" or house-percentage in fan-tan, usually 8 per cent of the winnings being deducted for the benefit of the *croupier* or proprietor of the gambling house.

Fan Tracery, in architecture, the decorative tracery on the surface of fan vaulting. It was used in late pointed work. Fan vaulting or fan-tracery vaulting is a very complicated mode of roofing or vaulting in which the vault is covered with fan-tracery. It is peculiar to English Gothic, very fine examples of it being found in Henry VII.'s chapel, Westminster, and St. George's Chapel, Windsor.

Fanariots. See PHANARIOTS.

Fanaticism, excessive zeal; unreasoning enthusiasm in religious matters. In ancient Rome the term fanatics was applied to such as passed their time in temples, and who, pretending to be inspired by the divinity, would burst into wild and frantic gestures, utter pretended prophecies, cut themselves with knives, etc. It has prevailed under different forms in all ages of the world; and one of its most remarkable and dangerous features is the tendency that it has to spread over large masses of people, as well as to favor measures of persecution. By an extension of the term it is also sometimes applied to other forms of extravagant enthusiasm which in their outward manifestation are accompanied with impetuosity and violence. Thus, we speak of political fanaticism, which, in affairs of state, displays itself in a violent and intolerant partisanship. Not unfrequently both kinds of fanaticism are found combined, and to this combination most of the religious wars which have desolated kingdoms are to be ascribed.

Fandango, a lively and voluptuous Spanish dance in triple time, said to be derived from the Moors. It is danced by two persons, male and female, and accompanied by the sounds of the guitar. The dancers have castanets which they beat in time to the measure, though sometimes the male dancer beats a tambourine.

Faneuil, fan'el or fun'el, **Peter,** American merchant: b. of a French Huguenot family, New Rochelle, N. Y., 1700; d. Boston 3 March 1743. The project of erecting a public market-house in Boston had already been discussed for some years, when in 1740 Faneuil offered, at a public meeting, to build a suitable edifice at his own cost, as a gift to the town; but so strong was the opposition to market-houses that, although a vote of thanks was passed unanimously, the offer was accepted by a majority of only seven. The building was commenced in Dock Square in September of the same year, and finished in two years. It comprised a market-house on the ground floor, and a town-hall with other rooms over it. In 1761 it was destroyed by fire; in 1763 it was rebuilt by the town; and in 1775, during the English occupation of Boston, was used for a theatre. In 1805 it was considerably altered and enlarged. During the Revolutionary period it was the usual place of meeting of the patriots, and from the stirring debates and important resolutions which were often heard within its walls, it gained the name of "the cradle of American liberty." It was extensively restored in 1900. The hall is some 80 feet square and contains many portraits and the large painting 'Webster replying to Hayne.' The lower story is still occupied as a market.

Faneuil Hall ("The Cradle of Liberty"), in Dock Square, Boston. There being no public market in Boston in 1740, Peter Faneuil offered to build one and give it to the city. It was finished in 1742,— a two-story brick building 100 by 40, containing not only a market in the basement, but rooms for town officers and a public hall for town meetings. It was destroyed by fire 13 Jan. 1761; rebuilt 1763, and used for town meetings during many years following. In 1805 it was doubled in size by adding a third story and moving a side wall back 40 feet, making the great hall (it holds 3,000 people) famous for the speeches of Webster, Choate, Sumner, Wendell Phillips, Everett, and others. The building is still used both for hall and market; the former contains some fine paintings, including Healy's 'Webster Replying to Hayne.' See Brown, 'Faneuil Hall and Market' (1901).

Fanfani, Pietro, pē-ā trō fän-fä'nē, Italian philologist, humorist, and novelist: b. Pistoia, Italy, 21 April 1815; d. Florence 4 March 1879. He founded in 1847 the 'Philological Record,' and afterward edited several other periodicals of a like character. His "vocabulary of Tuscan Usage" and other "vocabularies" are works of high authority. The 'Writ at Random,' and the whimsical satire 'The Laughing Democritus: Literary Recreations,' furnish examples of his brimming humor. His novels are: 'Cecco of Ascoli'; 'Paolina'; 'The Coachman and his Family'; etc.

Fanfare, in music, a short passage for trumpets. Certain flourishes in opera music are also called fanfares. Also any short, prominent passage of the brass instruments of an orchestra.

Fangwe. See FANS, a tribe.

Fannin, James W., American soldier: b. Georgia about 1800; d. Goliad, Texas, 27 March 1836. He removed to Texas in 1834 and in the Texas war of independence raised the "Brazo's Volunteers," a company which formed part of the army of Gen. Austin. Receiving orders from Gen. Houston to blow up Goliad and retire to Victoria he was attacked on the banks of Coleto Creek as he was retreating with women and children and a force of 350 men. The Mexicans were 1,200 strong and after a battle of two days he surrendered. Santa Anna instead of paroling the Americans, in accordance with the promise of Gen. Urrea, gave orders that all, excepting the women and children, should be shot.

Fanning, David, American freebooter: b. Wake County, N. C., about 1756; d. Digby, Nova Scotia, 1825. He was a carpenter by trade, but led a vagabond life. Late in the Revolutionary War he joined the Tories for the purpose of revenge; gathered a small band of despera-

FANEUIL HALL, BOSTON, MASS.

does like himself, laid waste to whole settlements and committed fearful atrocities. For these services he received a lieutenant's commission from the British commander at Wilmington. At one time he surprised a court in session and captured and carried off judges, lawyers, clients, officers, and citizens, and soon afterward seized Gov. Burke and his suite. The name of Fanning became a terror to the country, and he was outlawed. At the close of the war he fled to New Brunswick, where he became a member of the legislature.

Fanning, Edmund, American loyalist: b. Long Island, N. Y., 1737; d. London, England, 28 Feb. 1818. He was graduated from Yale in 1757; settled in North Carolina, where he became a member of the legislature, and as recorder for Orange County excited general dislike by his exactions. In 1771 he removed to New York and in 1777 organized the king's American regiment of foot. He was subsequently appointed governor of Nova Scotia by the English government and was governor of Prince Edward Island 1786–1805. In the English army he rose to the rank of general.

Fanning, John Thomas, American civil engineer: b. Norwich, Conn., 31 Dec. 1837. He served in a Connecticut regiment during the Civil War and was city engineer of Manchester, N. H., 1872–86. Since the last named year he has lived in Minneapolis. He has been connected with the planning and construction of various important public waterworks in New England and in the western States, and has published 'A Treatise on Hydraulic and Water Supply Engineering' (1877).

Fanning Islands, a group of coral islands, in the Pacific, between lat. 2° and 5° 49' N., and lon. 157° and 162° W. It comprises the islands of Jarvis, Christmas, Washington, Palmyra, and Fanning Island; area of the whole, about 260 square miles. Cocoanut and other tropical trees are found here. The islands of Fanning and Christmas belong to Great Britain. The group gets its name from an American sailor, Edmund Fanning, who discovered it in 1798.

Fanny, Aunt. See BARROW, FRANCES ELIZABETH.

Fanny Fern. See PARTON, SARAH PAYSON WILLIS.

Fano, fä'nō (ancient FANUM FORTUNÆ), a seaport of Italy, in a rich and fertile plain on the Adriatic, province of Pesaro e Urbino, 29 miles northwest of Ancona. It is surrounded by walls, built by the Emperor Augustus, and contains a triumphal arch, a cathedral with valuable paintings, a public library, and a fine theatre. Pop. commune 24,848.

Fanon, an ecclesiastical term of various applications. It was used to denote the cloth in which the deacon in the ancient or early mediæval Church received the oblations, and is now generally applied to a striped, oblong piece of silk gauze worn on the head and shoulders by the Pope in celebrating mass pontifically. It also designates the church banner carried in processions. In surgery, a fanon is a splint of a particular shape, formerly employed in fractures of the thigh and leg, to keep the bones in contact.

Fans, also known as **Fangwe Pahouins, Oshiba,** etc., an African people who emigrated from the interior to the coast of French Congo during the first half of the 19th century. They now number about 300,000 in the neighborhood of the mouths of the Ogoway and the Gaboon. They have been described by Du Chaillu, Burton, Lenz, Reade, and other travelers as a warlike and highly intelligent people, differing markedly from the surrounding negroid or Bantu tribes. Their complexion is rather light, their beard long, their frontal bone very prominent, and they are tall and well-built. They were formerly much given to eating human flesh, but their cannibalistic tendencies have been checked by contact with the Europeans of the coast regions.

Fans, instruments for producing an agitation of the air, and consisting of an extended flat surface, generally semicircular in outline. As hand-implements for cooling the air they have long been articles of luxury. Early Egyptian paintings prove familiarity with its use in a remote period. From a passage in the 'Orestes' of Euripides it appears that the Grecian fans were introduced from the East, that they were of a circular form, and were mounted plumes of feathers. Dionysius of Halicarnassus describes the courtiers of Aristodemus at Cumæ as attended by females bearing parasols and fans. Plautus mentions fan bearers as forming part of a Roman fine lady's retinue, and Suetonius describes Augustus as lying, during the heat of summer, in the shade, and fanned by an attendant. In the Middle Ages fans were used in the churches to chase away the flies from the holy elements of the Eucharist. Such a fan, known as a flabellum, is still used in the Greek and Armenian churches. The folding fan is said to have been a Japanese invention which originated in the 7th century, the idea having been supplied by the wing of the bat. From Japan the invention passed into China; but it was not till about the beginning of the 16th century that such fans began to be used in Europe, being introduced into Italy and Spain. The fan was first brought into European notoriety by Catharine de Medici, who introduced it in the folding form into France. Great sums were spent on the ornamentation of the fans first in vogue, and many were painted by Watteau. During the 16th and 17th centuries, they were used by gentlemen. In various nations and at various periods the manipulation of the fan has formed almost a separate language, especially for coquettes. Addison in his essay on the fan, in the 'Spectator,' and Disraeli in 'Contarini Fleming,' treat of this feminine art. They are said to have been introduced into England from Italy in the reign of Henry VIII.; and in the reign of Elizabeth they were framed of very costly materials, the body of ostrich feathers, the handle of gold, silver, or ivory, of curious workmanship. Walking fans were formerly in use. They were of large size and were employed to screen the face from the sun. The Chinese have greatly excelled in the art of making fans, those of the lacquered variety showing especial skill. For common use they make a cheaper sort, constructed of polished bamboo and paper. In Japan, where to this day the fan is an indispensable adjunct of the daily life of all classes, large rich fans are used in ceremonial dances in which they are accessories of peculiar significance. In Rome the pope is escorted on ceremonial occasions by attendants with flabella formed of peacock feathers. In Europe, France manufactures the greatest number of fans used by the world of fashion. A species of large fan known as a punkah is used in India for cooling the air of rooms and keeping down the temperature. Fans in the form of machines are used in agriculture for winnowing grain, the original form being very simple and dating back to primitive times. In metallurgy and other branches of manufacture fans are employed for ventilating and stimulating the combustion of fires; for the ventilation of mines; and for various other manufacturing purposes. The modern electric revolving fan is extensively used for cooling the air in public and private buildings.

Fans, Mine. See MINING.

Fanshawe, fan'shâ, **Anne Harrison,** LADY, an English memoirist: b. London, England, 25 March 1625; d. there 30 Jan. 1679 or 1680. Her admirably written and accurate observations of life and manners in many lands, preserved in 'Memoirs,' from which extracts have been published, are of historical value.

Fanshawe, Catharine Maria, English poet: b. Chipstead, Surrey, England, 6 July 1765; d. Putney Heath, Surrey, 17 April 1834. A lively fancy, brilliant wit, sound sense, and personal charm made this lady and her poetry admired in her own circle; but she rarely consented to publication, and only her riddle on the letter H, sometimes credited to Byron, is generally known, her stanzas not having been collected.

Fanshawe, SIR **Richard,** English diplomatist, poet, and translator: b. Ware, Hertfordshire, June 1608; d. Madrid, Spain, 26 June 1666. On the breaking out of the civil wars in 1641 he engaged actively in the royal cause. He was made a baronet in 1650, and sent on an embassy to Spain, and afterward appointed secretary of state for Scotland. He was taken prisoner at the battle of Worcester in 1651. In 1661 and 1662–3 he was employed on two several missions to the court of Lisbon, in the former of which he negotiated the marriage of Charles II. with Princess Catharine, and on his return in 1663 was advanced to a seat in the privy council. In 1664 he was sent ambassador to Madrid, and negotiated a peace between England, Spain, and Portugal. His poetical abilities were above mediocrity, as is evinced by his translations of the 'Lusiad' of Camoens, the 'Pastor Fido' of Guarini, the 'Odes' of Horace, and the fourth book of the 'Æneid' into English verse, and Fletcher's 'Faithful Shepherdess' into Latin.

Fantail, an Australian flycatcher of the genus *Rhipidura,* having a fan-like, and in some species prolonged, tail, which the bird opens and shuts gracefully as it tumbles about in the air when pursuing its agile prey. A familiar species is *R. mottacilloides,* whose habits are wagtail-like.

A warbler (*Cisticola cursitans*) of the Mediterranean countries and eastward, remarkable for its nest, which consists of soft materials enclosed in two leaves stitched together to sustain it, much after the method of the tailor-bird (q.v.).

A small variety of domestic pigeon, usually pure white, which holds its tail erect and distended like a fan.

Fantasia, fan-ta-zē'a, in music, a species of composition in which the author confines himself to no particular form or theme, but ranges as his fancy leads amid various airs and movements. Some writers, in defining this word, confine its meaning to extempore composition, and make this distinction between capriccio and fantasia; namely, that the former is a collection of singular and whimsical ideas strung together by an excited imagination, and written down at one's leisure, but the latter is an off-hand execution of whatever comes across the mind while playing on an instrument.

Fantee, or **Fanti,** făn-tē', a country of Africa, on the Gold Coast, which extends about 90 miles along the shore of the Atlantic, and 70 inland; lat. 5° 30' N.; lon. 1° W. The inhabitants, called Fantees, were at one time the most numerous and powerful people situated immediately on the Gold Coast; but their power was almost entirely broken after 1811 by invasions of the Ashantees. Their country now forms a district of the British Gold Coast Colony. The soil is fertile, producing fruits, maize, and tropical vegetation of nearly every variety. The custom of making small scarifications on the upper part of the cheek-bones and the back of the neck prevails among the Fantees. Their government is aristocratic. Their head chief is supreme judge or governor, and is attended by a council of old men. Each town has a chief. At one time they had several large cities. The country of the Fantees is populous and prosperous, owing to the protection afforded by the British settlements, and particularly by Cape Coast Castle. In 1873 they were again attacked by the Ashantees, who also threatened the British settlements, and compelled the government of Great Britain to send out an expedition under Sir Garnet (now Lord) Wolseley to suppress them. Consult: Barrow, 'Fifty Years in Western Africa'; Boyle, 'Through Fanteeland and Coomassii'; McDonald, 'The Gold Coast Past and Present.'

Fantoccini, făn-tō-chē'nē, an exhibition of puppets, or a dramatic representation on a small scale, performed by figures or dolls, an amusement of which the Italians are extremely fond, and which is frequently performed in a portable theatre — like that of Punch and Judy.

Fanum Fortunæ. See FANO.

Far from the Madding Crowd, a novel by Thomas Hardy, published 1874. It is perhaps the best example of his earlier manner, and of his achievements in the domain of comedy.

Farad (from Michael Faraday), the standard electrical unit, which is measured by the capacity of a condenser that with an electromotive force of one volt is able to overcome a resistance equivalent to one ohm in one second, or in other words the resistance offered by a cylindrical copper wire, 250 feet long, 1/20 inch in diameter, the ohm being the magneto-electric unit. See ELECTRICAL UNIT.

Faraday, Michael, English scientist: b. Newington Butts, England, 22 Sept. 1791; d. Hampton Court 25 Aug. 1867. He received little or no education and was apprenticed to the trade of a bookbinder. During his term of apprenticeship, a few scientific works fell into his hands, which he read with avidity, and forth-

MICHAEL FARADAY, F.R.S.

with devoted himself to the study of, and experiments in, electricity. Having attended the lectures given in 1812 by Sir Humphry Davy, and taken notes thereon, he sent them to that philosopher, and besought some scientific occupation. The reply was prompt and favorable. In 1813 Faraday was appointed chemical assistant, under Sir Humphry, at the Royal Institution. Faraday discovered in 1820, the chlorides of carbon, and, in the following year, the mutual rotation of a magnetic pole and an electric current. These were strong encouragements to proceed on the path of discovery, and led to the condensation of gases in 1823. In 1829 he labored hard, and, as he thought at the time, fruitlessly, on the production of optical glass; but though unsuccessful in his immediate object, his experiments produced the heavy glass which afterward proved of great assistance to him in his magnetical investigations. In 1831 the series of 'Experimental Researches in Electricity,' published in the 'Philosophical Transactions,' began with the development of the induction of electric currents, and the evolution of electricity from magnetism. Three years later Faraday established the principle of definite electrolytic action, and, in 1846 received at the same time the Royal and the Rumford medals for his discoveries of diamagnetism, and of the influence of magnetism upon light respectively. In 1847 he discovered the magnetic character of oxygen, and, also, the magnetic relations of flame and gases. His papers, including other contributions to the store of modern science, are too numerous to mention in detail. It should be observed that the 'Researches,' though termed 'Experimental,' contain many hypothetical ideas, and many inquiries into theories generally adopted up to their time. Among these may be specified the considerations respecting static induction, atmospheric electricity, and those relating to lines of force, both physical and representative, on which having sufficiently stated his views, he was content to leave them for solution to time and future experience. It may be added that his last hypothetical view relates to the conservation of force, and that one of his latest papers treats of the division of gold and other metals. In 1833 Faraday was appointed professor of chemistry in the Royal Institution, London, which chair he continued to hold until his death. In 1835 he received from government a pension of $1,500 per annum in recognition of his eminent scientific merits. In 1836 he was appointed a member of the senate of London University. From 1829 to 1842 he was chemical lecturer at the Royal Academy. In 1823 Faraday was elected corresponding member of the French Academy. In 1825 he was chosen a Fellow of the Royal Society, and in 1832 made a D.C.L. of Oxford University. He was, besides, a knight of several of the European orders, and a member of the chief learned and scientific societies in Europe and the United States. See Tyndall, 'Faraday as a Discoverer' (1868); Bence Jones, 'Life and Letters' (1870); J. H. Gladstone, 'Life of Michael Faraday' (1872); Thompson, 'Michael Faraday: his Life and Work' (1898).

Faraday Effect. See LIGHT.

Faradism. See ELECTRICITY IN MEDICINE.

Farafeh. See FARAFRA.

Farafra, fa-rä'fra, or **Farafeh,** an oasis of the Libyan Desert, in Africa, containing several ruins of Greek and Roman origin. A coarse woolen cloth and earthenware are the manufactures.

Farallones (fä räl-yō'nes) **Islands,** in the Pacific, off the coast of California, about 28 miles from the entrance to the Golden Gate; a group of six small rocky islands. A large number of rabbits are found on the islands and many sea-lions on the coast. The islands are owned by a company who market the eggs of the sea-gulls and murres (allied to the auk). A lighthouse, with all modern equipment, on the southern island, is 360 feet above the water.

Farandola, fa-ran'-dō la or **Farandole,** fa-ran'dōl, a dance with various figures, popular among the peasants of the south of France and the neighboring part of Italy. It is performed by men and women taking hands, and forming a long line, and winding in and out with a waving motion. The dance is often used in excited gatherings. The figures of the farandola, by the name of the Spanish dance, were once well known in English ball-rooms.

Farce (Ital. *farsa,* from Lat. *farcire,* "to stuff"), a dramatic piece of a broad comic character. The difference between it and comedy proper is one of degree and not of kind. The aim of both is to excite mirth; but, while the latter does so by a comparatively faithful adherence to nature and truth, the former assumes a much greater license, and does not scruple to make use of any extravagance or improbability that may serve its purpose. It does not, therefore, exhibit, in general, a refined wit or humor, but consists of ludicrous rencontres, exaggeration of personal peculiarities, and dialogues provocative of fun. The beginnings of Greek and Roman comedy consist of rustic farces or pantomimes (see ATELLANÆ FABULÆ); the first farces, in the modern sense, were composed by the fraternity of the Bazoche (q.v.) in Paris, as a contrast to the ecclesiastical plays performed by the religious orders. The most widely celebrated and most important of early farces is that of the advocate 'Maistre Pierre Patelin,' which was acted in the 15th century, and quickly spread itself over Italy and Germany. It is full of genuine comic quality, and its dialogue has brightness and reality. The *commedia dell 'arte* of Italy were of a farcical nature. Molière elevated and refined the farce into his wonderful series of comedies of character. In England the origin of the modern farce dates from about the commencement of the 18th century. Few farces have kept a place in literature. See COMEDY; DRAMA.

Consult: Chevaldin (L. E.), 'La Farce de Patelin et ses Imitations' (Paris 1889), from the work by Dr. K. Schaumburg.

Farcy, in horses, depends upon the same causes as glanders (q.v.) — in fact, is an outward manifestation of glanders. The absorbent vessels of the superficial parts of the body, but usually those of one or both hind limbs, are inflamed, tender, swollen, hard, and knotted. The vitiated lymph thus poured out softens, and ulcers or farcy buds appear. Unlike the ulcers of glanders, they are sometimes thought to be curable, but an animal apparently cured is not safe to be with other horses, as the *contagium* —

the *Bacillus mallei* — almost invariably remains, and the animal is thus a centre of infection and a source of danger.

Fardel-bound, a term applied to sheep and cattle when suffering from a disease caused by the retention of food in the third stomach, or maniplies. The disease frequently arises from the eating of over-ripe clover, vetches, or rye grass. The food being tough and indigestible, finally causes chronic inflammation.

Fareham, fār'am, England, a market town in Hampshire, at the head of a short arm of the Portsmouth harbor, and six miles northwest of Portsmouth. Pop. (1901) 8,246.

Farel, Guillaume, gē yōm fä-rel, Swiss reformer: b. near Gap, Dauphiny, 1489; d. Neufchâtel, Switzerland, 13 Sept. 1565. At an early period the study of the Bible led him to reject many of the chief doctrines of the Roman Catholic Church. At Basel, in 1524, he publicly sustained several theses in support of Protestantism, and he afterward preached in Strasburg, Montbéliard, and elsewhere. In 1530 he secured the public adoption of the reformed doctrines in Neufchâtel. Geneva, however, became the principal scene of his labors. Here, in the religious conferences of 1534 and 1535, he defended his beliefs so successfully that the reformed parishes not only obtained permission to hold public religious services, but the council formally embraced the Reformation. In concert with Calvin he took an active part in 1536 at the disputation in Lausanne, when the Reformation was embraced. In consequence of a quarrel, arising out of an attempt to enforce a stricter moral discipline, he was banished from Geneva in 1538, and ultimately took up his residence in Neufchâtel. See Life, by Bevan (1893).

Fargo, William George, American capitalist: b. Pompey, N. Y., 20 May 1818; d. Buffalo, N. Y., 3 Aug. 1881. He became Buffalo agent of the Pomeroy Express Company in 1843; established the first express company west of Buffalo, in 1844; and in 1868 became president of the great corporation controlling the whole West, the Wells-Fargo Express Company.

Fargo, N. D., city, county-seat of Cass County; at the head of navigation on the Red River; on the Chicago, M. & St. P., the Northern P., and the Great N. R.R.'s; opposite Moorehead, Minn. It contains a United States land office, Fargo College (Cong.), the State Agricultural and Mechanical College, St. John's Hospital, high school, court-house, waterworks, street railroad, and electric light plants, several banks. and a number of daily and weekly newspapers. It has the car shops of the Northern Pacific Railroad, flour-, planing-, and paper-mills, large grain elevators, a brewery, and large brick yards. Pop. (1900) 9,589.

Fargo College, a coeducational institution in Fargo, N. D.; founded in 1888 under the auspices of the Congregational Church. In 1901 there were in attendance 367 students.

Fargus, Frederick John ("Hugh Conway"), English novelist: b. Bristol, England, 26 Dec. 1847; d. Monte Carlo 15 May 1885. He adopted his pseudonym from the school frigate Conway, stationed on the Mersey, which he entered when he was 13, for the purpose of training for a seafaring life. He subsequently entered the auctioneer business, employing his leisure in writing clever newspaper verse and occasional tales. Some songs of his were accepted and published in 1878, a volume of verse in 1879; but it was the issue and rapid sale of his melodramatic story, 'Called Back' (1884), which made him famous. He then went to London, where he adopted the profession of authorship. His other writings include: 'Dark Days' (1884); 'A Family Affair' (1886); 'Slings and Arrows'; 'A Cardinal Sin' (1883); 'Bound Together' (1884).

Faria, fä-rē'ä, **Manoel Severim de,** Portuguese author: b. Lisbon, Portugal, 1583; d. Evora 25 Sept. 1655. He devoted many years to the study of his country's literature, giving his researches and thought a lasting form in 'Various Essays' (1624), containing appreciations and biographies of Camoens and other great writers. He also wrote 'Jottings of Portugal' (1655).

Faria y Sousa, fä-rē'ä ē sō'zä, **Manoel,** Portuguese historian and lyric poet: b. near Pombeiro, in Portugal, 18 March 1590; d. Madrid, Spain, 3 June 1649. A passion for a beautiful girl first awakened his poetical genius. He celebrated her under the name of Albania in his sonnets, married her in 1613, and went to Madrid. But he did not succeed there, and returned to Portugal. He also visited Rome, and gained the notice of Urban VIII. Among his writings are: 'Discursos Morales y Politicos'; 'Epitome de las Historias Portuguesas'; and a collection of poems called 'Fountain of Aganippe' (Fuente de Aganipe, Rimas varias, 1644–6). His style was pure and strong, and his descriptions full of vigor.

Faribault, fãr-ĭ-bō', Minn., city, county-seat of Rice County; at the confluence of the Cannon and Straight rivers; on the Minneapolis & St. L. and the Chicago, M. & St. P. R.R.'s; 53 miles south of St. Paul. It has manufactories of pianos, carriages, furniture, boiler works, foundry products, and rattan goods, and canning establishments, breweries, flour-, planing-, and woolen-mills. Faribault is noted for its fine schools, both public and private. The State schools for the deaf, dumb, blind, and feeble-minded are located here. The Seabury Divinity School, the Shattuck Military School for boys and the St. Mary's School for girls are flourishing institutions, all three of which are under the auspices of the Protestant Episcopal Church; Bethlehem Academy is in charge of the sisters of St. Dominic. Faribault was the home of Bishop Whipple (q.v.). Faribault became noted in 1891, because of a controversy which arose regarding the incorporation of parish schools into the public school system. It was called by many then a new movement; but it was similar to the plans which had long been in existence in several cities and towns in other parts of the United States; as Poughkeepsie, Corning, Ogdensburg, and Plattsburg in the State of New York; and several places in Connecticut, Ohio, and in other States. Pop. (1900) 7,868. See Parish Schools.

Faridpur, Furidpur, fũr-ēd-poor, or **Dacca Jelalpur,** däk'kä jel-ŭl-poor', a district in the Dacca division; area, 2,267 square miles. Pop. (1891) 1,797,320.

Farina, fä-rē'nä, **Salvatore,** Italian novelist: b. Sorso, Sardinia, 10 Jan. 1846. His tales were successful from the first, which was ‘Two Amours’ (1869). Among the others are: ‘A Secret’ (1870); ‘Forbidden Fruit’; ‘Romance of a Widower’; ‘Dounina's Treasure’; ‘Courage and Onward’; ‘Little Don Quixote’ (1890); ‘Living for Love’ (1890); ‘For Life and for Death’ (1891). The sympathy with lowly life and the rich humor of his stories have gained him the title of "The Italian Dickens." He is the best known abroad of all Italian novelists.

Farina (Lat. "flour"), a term popularly applied to a food product made from white maize, having grains coarser than those of meal, but finer than hominy. A somewhat similar preparation is made from the inner portion of wheat grain. Farinaceous dishes, in which farina is combined with milk, fruit, etc., furnish a light and nutritious diet for invalids and the young. In early works on botany the pollen of flowers was styled farina.

Farinato, fä-rē-nä'tō, or **Farinati,** fä-rē-nä'tē, **Paolo,** Italian painter: b. Verona 1524; d. there 1606. He took his style of painting from Veronese, and Guilio Romano. His works are characterized by wealth of imagination, graceful but not always correct drawing, combined with harmonious coloring. He finds his modern counterpart in the English Rosetti. He painted both in oil and fresco. There are some fine frescoes of his in the choir of San Nazaro at Verona; his wonderful ‘Miracle of the Bread and Fishes’ (1603) is in the church of San Georgio Maggiore, and his ‘Finding of Christ in the Temple’ is in the Berlin Museum.

Farinelli, fä-rē-nel'lē (real name Carlo Broschi), Italian soprano singer: b. Naples 24 Jan. 1705; d. Bologna 15 Sept. 1782. He studied under Porpora, and went from Rome to Vienna, where the Emperor Charles VI. loaded him with rich presents. In 1734 Farinelli went to London, and by the magic of his singing so delighted the public that Handel was obliged to dismiss a rival company over whom he presided, in spite of all his powers and popularity. Many extraordinary stories are related of Farinelli's vocal skill, and his command over the feelings and sympathies of his audience appears to have been unrivaled.

Faringdon, făr'ing-dôn, or **Great Faringdon,** England, a market town in the county of Berks; 16 miles southwest of Oxford. Pop. 3,133.

Farini, Luigi Carlo, loo-ē'jē kär'lō fä-rē'nē, Italian historian: b. Russi 22 Oct. 1812; d. 1 Aug. 1866. He studied medicine at Bologna, but early entered upon a political career, becoming minister of public instruction in 1850, of commerce in 1861, and president of the council in 1862 during Cavour's administration. His influence contributed much to the union of central Italy with the kingdom of Victor Emmanuel II. His ‘History of the Roman State from 1815 to 1850’ (1850) was translated into English; and his ‘History of Italy,’ a continuation of Botta's celebrated work, is a performance of standard merit.

Farjeon, fär'jun, **Benjamin Leopold,** English novelist of Jewish descent: b. London 1833; d. Hampstead 1 Aug. 1903. He spent some years in Australia and New Zealand as journalist and novelist, and was the editor and co-proprietor of the first daily newspaper published in the latter country. His first successful novel was ‘Grif: a Story of Australian Life’ (1870). It was followed in 1871 by ‘Blade-o'-Grass,’ and in 1872 by ‘Joshua Marvel.’ Later works of his include: ‘London's Heart’ (1873); ‘Bread and Cheese and Kisses’ (1874); ‘Love's Victory’ (1875); ‘At the Sign of the Silver Flagon’ (1876); ‘Solomon Isaacs: a Christmas Story’ (1877); ‘Aaron the Jew’; ‘Great Porter Square: a Mystery’ (1884); ‘The House of White Shadows’ (1884); ‘Self-doomed’ (1885); ‘Set in a Silver Sea’ (1886); ‘The Nine of Hearts’ (1886); ‘The Tragedy at Featherstone’ (1886); ‘The Secret Inheritance’ (1887); ‘Toilers of Babylon’ (1888); ‘Miriam Rozella’ (1897); ‘The Betrayal of John Fordham’ (1897); ‘Samuel Boyd of Catchpole Square’ (1899); ‘The Mesmerists’ (1900); ‘Pride of Race’ (1900); ‘The Mystery of the Royal Mail’ (1902); etc. Farjeon has been compared with Dickens in his "sentiment and minute characterization." The comparison is not altogether a happy one, and the knowledge that it had been made affected the novelist's style somewhat, and not for the better.

Farley, Harriet. See Donlevy, H. F.

Farley, James Lewis, Irish journalist: b. Dublin, Ireland, 9 Sept. 1823; d. London, England, 12 Nov. 1885. Established in Turkey as a bank official, he became correspondent of two or three great London dailies and speedily made himself an authority on Turkish questions. His books include: ‘The Resources of Turkey’ (1862); ‘Turkey: Its Rise, Progress, and Present Condition’ (1866); and ‘Modern Turkey’ (1872).

Farley, John Murphy, American Roman Catholic prelate: b. Newton, Hamilton, county of Armagh, Ireland, 20 April 1842. He began his college studies in Ireland, although only a youth when he came with his parents to America. He continued his studies for the priesthood in St. John's College, Fordham, N. Y., and St. Joseph's Seminary, Troy, N. Y., and in the American College in Rome. He was ordained in Rome 11 June 1870, and the same year returned to the United States to begin work in St. Peter's parish, New Brighton, Staten Island. In 1872 Archbishop McCloskey of New York chose him for private secretary. In 1884 Pope Leo XIII. made him private chamberlain with the title monsignor; and in 1891 he was made vicar-general of the archdiocese of New York. In 1892 he was made domestic prelate to Leo XIII., and in 1895 prothonotary apostolic, all of which positions gave him special privileges. In December 1895 he was consecrated titular bishop of Zeugma, and became assistant to the archbishop of New York. For several years he was permanent rector of St. Gabriel's Church, New York.

When the see of New York became vacant by the death of Archbishop Corrigan (1902), the lists of names sent to Rome by the suffragan bishops and permanent rectors, each had at the head the name of Bishop Farley as first choice for archbishop. He received his appointment from Leo XIII., but the pallium was conferred under Pius X., on 12 Aug. 1903. He is the fourth archbishop of New York and governs one of the largest Roman Catholic dioceses in the world, containing about 1,200,000 members of the Church. He is the metropolitan of the ecclesiastical province of New York, which is composed of eight dioceses outside the archdiocese; six in the State of New York and two in New Jersey. The author of the 'Life of Cardinal McCloskey,' Archbishop Farley has also been a contributor to various magazines, and quite recently he has received emphatic proof of Pope Pius X.'s favor by being made assistant at the pontifical throne. At present (1905), the archdiocese of New York comprises a Catholic population estimated at 1,200,000; 754 priests; 289 churches; 198 parochial schools; 1 theological seminary; 6 orphanages; 20 hospitals and other institutions, benevolent and educational.

Farlow, William Gilson, American botanist; b. Boston, Mass., 17 Dec. 1844. After graduating at Harvard, he spent several years in Europe pursuing his favorite study and became professor of cryptogamic botany at Harvard in 1879. His publications treat mainly of marine algæ, fungi, and diseases of plants. Upon these subjects, and particularly upon cryptogamic botany, he is considered an authority. He also published: 'The Potato Rot' (1875); 'Diseases of Olive and Orange Trees' (1876); 'The Marine Algæ of New England' (1881).

Farm, a tract of land devoted to agriculture, under the management of owner or tenant. The size of farms and their tenure differ very much in different countries. On the continent of Europe, where peasant proprietaries, cultivation by the metayer system (q.v.), and mixed tenures prevail, farms are generally small. In England, where the land is in the hands of a comparatively small number of proprietors, and is let out to farmers who pay a fixed rent and make a trade of cultivating their holdings, these are in many localities large compared with continental farms. In the United States the majority of farms are owned by those who operate them. In 1900 between 54 and 55 per cent were so operated. In 1890 tenants operated 28.4 per cent of all the farms, and in 1900, 35.3 per cent. A comparatively small number are worked by part owners. The short tenure of land usually prevailing in England and Ireland has given rise to many disputes about compensation for improvements effected by tenants, etc. In Scotland it has been customary to give a lease for 19 years.

In these statistics the term «farm» includes, as defined by the twelfth census of the United States, «all the land, under one management, used for raising crops and pasturing live stock, with the wood lots, swamps, meadows, etc., connected therewith. It includes also the house in which the farmer resides, with all other buildings used by him in connection with his farming operations.» As thus broadly defined the 5,739,657 farms in the United States in 1900 embraced, in addition to the general farm, the cotton, the sugar, and the rice plantations of the country; large ranges in the western States (of which however the area actually owned or leased is very small) — as well as smaller stock farms — the extensive farms devoted to the raising of grain; those producing chiefly hay and forage, tobacco, hemp, or hops, orchard fruits or small fruits; truck farms; dairy farms; poultry farms; bee farms; florists' establishments; nurseries, etc. The number of farms in the United States has increased so rapidly for several decades that in 1900 there were nearly four times as many as in 1850 and 25.7 per cent more than in 1890. Since 1880 the average size of farms has increased, being in 1900 146.6 acres. The number of farms under 3 acres is 41,882; and of farms of 1,000 acres and over 47,276. The medium-sized farms containing from 100 to 174 acres represent the highest value per acre. The total value of farm property in the United States is a little over $20,514,000,000. See AGRICULTURE; DAIRY INDUSTRY, AMERICAN; LIVE STOCK; FARM MACHINERY, AMERICAN.

Farman, Elbert Eli, American jurist: b. New Haven, Oswego County, N. Y., 23 April 1831. He was graduated at Amherst College in 1855, and admitted to the bar in 1858 and to the United States courts in 1862. He studied international law in Berlin and Heidelberg, Germany, in 1864–7; was district attorney of Wyoming County, N. Y., in 1868–75; United States diplomatic agent and consul-general at Cairo, Egypt, in 1876–81; was a member of the International Commission to revise the judicial codes of Egypt in 1880–1; judge of the mixed tribunal of Egypt in 1881–4; and United States member of the International Commission which examined the claims of the inhabitants of Alexandria for losses arising from the bombardment in 1882, 1883, and 1884. He secured the obelisk «Cleopatra's Needle» as a gift of the khedive to New York, in 1879; made large collections of ancient coins and Egyptian antiquities which he gave to the Metropolitan Museum of Art in New York.

Farman, Ella. See PRATT, ELLA FARMAN.

Farmer, Henry Tudor, American poet: b. England 1782; d. Charleston, S. C., January 1828. While very young he emigrated to Charleston, S. C., where he continued to reside till his death. He published a small volume of poems entitled 'Imagination, the Maniac's Dream, and Other Poems' (1819); also an 'Essay on Taste.'

Farmer, John, American genealogist: b. Chelmsford, Mass., 12 June 1789; d. Concord, N. H., 13 Aug. 1838. He published in 1829 a much valued 'Genealogical Register of the First Settlers of New England.'

Farmer, Lydia Hoyt, American miscellaneous writer: b. Cleveland, Ohio, 1842; d. 27 Dec. 1903. She was married to E. J. Farmer. Her works include: 'Aunt Belindy's Point of View'; 'The Doom of the Holy City'; 'A Story Book of Science'; 'A Knight of Faith'; 'Short History of the French Revolution'; 'Girls' Book of Famous Queens'; 'What America Owes to Women'; etc.

Farmer, Moses Gerrish, American electrician; b. Boscawen, N. H., 9 Feb. 1820; d Chicago, Ill., 25 May 1893. He was graduated at Dartmouth College in 1844. He invented several electro-motors, one of which he used in his workshop to drive a lathe, and another on a miniature railway. On this railway he transported by electricity the first passengers ever so carried in the United States. In 1847 he moved to Framingham, Mass., and invented the telegraph fire alarm. In 1865 he invented a thermo-electric battery and also built the first dynamo, and in 1880 patented an automatic elec-

MOST REVEREND JOHN M. FARLEY, D.D.,

Archbishop of New York.

tric light system. Besides these inventions he brought to light and perfected many others of general utility.

Farmer, Richard, English Shakespearian scholar: b. Leicester 28 Aug. 1735; d. Cambridge, England, 8 Sept. 1797. In 1767 he published his 'Essay on the Learning of Shakespeare,' which passed through several subsequent editions. In it he showed that Shakespeare's knowledge of classical subjects was entirely obtained through translations, which he often followed very closely. He was appointed master of Emmanuel College, Cambridge, in 1775, and was a prebendary of Canterbury 1782–8, when he was appointed to a residentiary prebend in St. Paul's, London.

Farmers' Alliance, a national organization for improving agricultural conditions, advancing social life, securing favorable legislation, etc.; at first non-political, then political, then non-political again. Originating as a State body in Texas about 1876, it coalesced in 1887 with similar State bodies into a national one; and in 1889 joined the Knights of Labor in a common political party called the National Farmers' Alliance and Industrial Union, with a platform demanding more greenbacks, unlimited free coinage of silver, no national banks, anti-speculation laws, and government ownership of all transportation lines. The southern branch added a demand for government loans at low rates, and sub-treasuries to buy and store farm products. In the West in 1890 the party put up its own candidates; in the South it adopted and dictated the Democratic; it carried the Kansas and Nebraska legislatures, held the balance in Illinois, Minnesota, and South Dakota, and elected nine national representatives, and one senator each from South Carolina (nominally Democrat), Kansas, and South Dakota. In 1892 it fused with others and called itself the People's Party (q.v.), and nominated for President James B. Weaver, who received over 1,000,000 votes; but the southern branch declined to change its political affiliations, and seceded, the Alliance proper going out of politics again.

Farmers' Institutes, gatherings of farmers held annually in the various States, sometimes under the direct management of the agricultural colleges and sometimes controlled by other State officers. The object of these institutes is in great part the bringing together of the workers in agricultural science and the practical farmers, for the discussion of questions of mutual interest. The latest agricultural theories are presented and discussed and compared with the result of practical tests and long experience. The development of farmers' institutes has been chiefly due to the impetus given to the agricultural interests of the country by the Morrill Land Grant Act of 1862; yet they are to some extent an outgrowth from agricultural organizations existing previous to that date. These gatherings are held regularly in over 40 States. In 1899 over 2,000 institutes were held in this country, and the special appropriations for this purpose aggregated over $140,000, not including $30,000 funds estimated as expended from other sources. Pennsylvania and New York lead in the number of institutes, each holding 300 or more annually. In Wisconsin the institutes, numbering 120, are part of the university course in agriculture. Michigan has 200, attended by 120,000 farmers. In Ohio, 88 counties hold institutes. The meetings are generally in the winter when the farmers are free to attend them. The morning sessions are principally given to addresses with discussions, question-box methods, etc., and in the evenings there are popular lectures.

Farmers so frequently demand on the part of institute workers a wide range of scientific and practical knowledge, and the latest information regarding agricultural progress throughout the world, that it is impossible to meet the demand made on agricultural colleges and experiment stations in this direction. Under different names, meetings of farmers in many respects similar to those in the United States are held in other countries. In some parts of Europe, teaching of farmers by itinerant instructors is very thoroughly organized. See AGRICULTURE; AGRICULTURE, DEPARTMENT OF; AGRICULTURAL EXPERIMENT STATION; COLLEGES, LAND GRANT.

Farmers' National Congress, an organization having for its object the advancement of the agricultural interests of the Union, and composed of the same number of delegates from each State (or Territory) as the latter is entitled to in its representation in the United States Congress. The delegates are appointed by the governors of their respective States or by some other State official. All heads of State bureaus of agriculture are considered members, and one representative from each agricultural college.

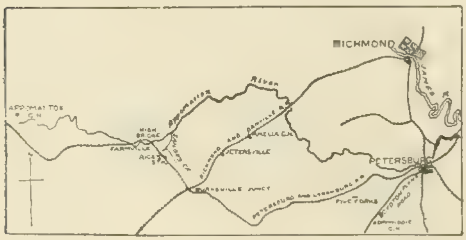
Farming. See AGRICULTURE; AGRICULTURAL CHEMISTRY; DAIRYING; DAIRY CATTLE; etc.

Farmington, Maine, town, county-seat of Franklin County, on the Sandy River and the Maine Cent. and Sandy River R.R.'s; 30 miles northwest of Augusta, on a direct route from the south to Rangeley Lakes. It is a business and educational centre, and has several banks, hotels, a courthouse, a weekly paper, and some manufactories. The town includes several villages, of which Farmington Village (incorporated) is chief. Farmington Academy (1807) was succeeded in 1863 by a State normal school, which has graduated over 1,300 teachers. The Abbott Family School for Boys (1844) opened in 1903 with new buildings. Cutler Memorial Library (1903) is a model granite building. Here for years lived the author Jacob Abbott (q.v.); John S. C. Abbott (q.v.), was once a pastor here; and this is the birthplace of Lillian Norton (Mme. Zoltan Döme), the prima donna, known as Madame Nordica. Pop. (1900) 3,288.

Farmington, Mo., city, county-seat of Saint François County; about 25 miles from the nearest point on the Mississippi. It is two miles from a railroad station (De Lassus). It is the site of the Farmington Baptist College, Elwood Seminary for Girls, and Carleton Institute. Its manufactures are flour, lumber, wagons, carriages, agricultural and mining implements. There are lead-mines near. Pop. (1900) 1,778.

Farmville, Va., town, county-seat of Prince Edward County; about 40 miles southeast of Lynchburg; on the Appomattox River, and the Norfolk & W. R.R. Here is the State Female Normal School. Farmville has a large manufacture of tobacco. Pop. (1900) 2,471.

Farmville and High Bridge, Engagements at (and THE SURRENDER OF THE ARMY OF NORTHERN VIRGINIA AT APPOMATTOX COURT-HOUSE). Farmville, on the south bank of the Appomattox, 70 miles southwest of Richmond, is noted as the place where Gen. Grant opened his correspondence with Gen. Lee which led to the surrender at Appomattox. After the battle of Five Forks (1 April 1865) and the successful assault on the Petersburg lines (2 April), Lee retreated and Grant pursued. Sheridan, with his cavalry and the Fifth corps, 3 April, pushed for the Danville railroad, keeping south of the Appomattox, followed by the Second and Sixth corps in the direction of Amelia Court-house, while Gen. Ord with the Twenty-fourth corps and a division of the Twenty-fifth, moved along the South-side railroad for Burkesville. On 4 April Sheridan struck the Danville road near Jetersville, and learned that Lee was at Amelia Court-house, eight miles northeast. He immediately entrenched the Fifth corps and awaited the arrival of Gen. Meade with the Second and Sixth corps. Meade found the roads so obstructed with Sheridan's cavalry that he did not get up until the afternoon of 5 April. Ord reached Burkesville on the evening of the 5th. He had been directed by Grant to cut the bridges in Lee's front, to intercept his movements toward Danville and Lynchburg, and await orders at Burkesville. To cut the High Bridge, four miles east of



Farmville, Ord, before daybreak of the 6th, sent two small infantry regiments (54th Pennsylvania and 123d Ohio), and 80 officers and men of the 4th Massachusetts cavalry, all under command of Col. Francis Washburn, with orders to push rapidly for the bridge and burn it. After Washburn had gone, Ord sent Gen. Theodore Read, his chief-of-staff, with a small party to overtake him and reconnoitre well before moving up to the bridge. Soon after Read had gone, Ord received a despatch from Sheridan that Lee was moving west of Jetersville and making apparently for Burkesville, upon which he put his command in position to meet him and sent an officer to caution Read that Lee's army was in his rear and that he must return by pressing on, crossing the Appomattox, and going around by Prince Edward Court-house. This last officer was driven back by Lee's cavalry. Read overtook Washburn, took the cavalry into Farmville, examined the country, returned to the infantry and pushing on, was within two miles of High Bridge, when about noon, he ran into Lee's advance, Rosser's and Munford's divisions of cavalry. Read and Washburn drew up the little band of cavalry and 500 infantry and began one of the most gallant fights of the Civil War. Again and again they led the cavalry in successive charges. Read and Washburn fell mortally wounded, and at last not an officer of the cavalry remained alive or unwounded, to lead the men, and the entire command, cavalry and infantry, was enveloped and surrendered.

At 6 A.M. 6 April, the Second, Fifth, and Sixth corps moved from Jetersville up the line of the Danville road toward Amelia Court-house, where it was hoped to intercept Lee, but during the night Lee had moved west, and when this was discovered, after a march of four miles, the advance on Amelia Court-house was suspended and the three corps marched westward parallel to Lee's line of retreat and endeavoring to head him off or bring him to a stand. The Second corps came up to Gordon's corps at Flat Creek and was for a time checked but, fording the creek, drove Gordon off and followed him to Sailor's Creek, where he made a stand, but was again driven with a loss of 13 colors, three guns, several hundred prisoners, and more than 200 wagons. During the day the Second corps had taken about 1,700 prisoners, four guns, and more than 300 wagons and ambulances. Its loss was about 400 men. While the Second corps was thus engaged, the Sixth corps on its left, with the cavalry divisions of Crook and Merritt had overtaken and attacked the commands of Ewell and Anderson on Sailor's Creek, routed them with a severe loss in killed and wounded, and took many thousand prisoners, among them six general officers, including Gen. Ewell. The Confederates continued their retreat. Longstreet with the divisions of Field, Heth, and Wilcox marched to Farmville, crossed to the north bank of the Appomattox and, on the morning of the 7th, began to move out on the road passing through Appomattox Court-house to Lynchburg. Fitz Hugh Lee with all his cavalry followed Longstreet. Gen. Gordon with the other half of Lee's army, crossed at High Bridge. On the morning of the 7th the Union army continued the pursuit, the cavalry, with the exception of one division, and the Fifth corps moving by Prince Edward Court-house; Ord, with his command, the Sixth corps and Crook's cavalry division on Farmville; the Second corps by the High Bridge road. With great difficulty Crook's cavalry waded the river above Farmville, and Gregg's brigade in moving out was fiercely assailed by Fitz Hugh Lee and driven back across the river, Gregg and many of his men being captured. Meanwhile Ord and the Sixth corps had come up to find the bridges destroyed, the water too deep for fording, and Lee's army in plain view on the opposite bank, drawn up for battle. The Second corps, pursuing Gordon, came to High Bridge just as Gordon's corps and Mahone's division had crossed and set fire to it and the wagon road bridge below it. Barlow, whose division was in advance, threw forward his head of column, which seized the wagon road bridge, extinguished the fire, and moved across, Mahone's division after some sharp skirmishing, retiring in a northwest direction, Gordon's corps moving along the railroad toward Farmville. Barlow followed Gordon, while Humphreys led Miles' and De Trobriand's divisions after Mahone and at 1 P.M. came up to Lee's army in an entrenched position, its left four miles from Farmville, on the crest of a long slope of open ground, covering the roads to Lynchburg. Poague's 16 guns opened on him, he threw forward skirmishers, and an unsuccessful attempt was made to take the position in flank. Barlow was sent for but did not get up until sunset. Meanwhile Miles saw an opening and attacked with part of a brigade and was repulsed with considerable loss. Barlow, who had followed Gordon, attacked him and succeeded in cutting off a large train of wagons, which he destroyed, and then rejoined his corps, which bivouacked within 100 yards of Lee's position. The loss of the Second corps during the day was 571, and it had captured 19 guns, many wagons, and had held Lee from continuing his retreat, until such time as Sheridan and Ord were fast gaining his line of escape.

At 5 P.M. Gen. Grant, from his headquarters at Farmville, wrote Gen. Lee asking the surrender of his army. This was sent through the Second corps lines at half past eight, and within an hour Lee replied, asking the terms that would be offered on condition of his surrender. During the night Lee retreated, Gordon leading and Longstreet bringing up the rear. The Second and Sixth corps followed Longstreet closely, and Sheridan, with his cavalry, followed by the Fifth corps and Ord's command, marched on the south side of the Appomattox, captured at Appomattox Station four trains of cars loaded with supplies for Lee's army, 25 guns, and a large park of wagons, and drove Lee's advance forces back to Appomattox Court-house. On the morning of 9 April Sheridan advanced but his cavalry was being pushed back just as Ord, who had marched all night, had formed in his rear, and the Army of Northern Virginia had made its last effort. Sheridan and Ord were in its front; the Second and Sixth corps were close on its rear, negotiations were in progress, hostilities were suspended and about 3 o'clock in the afternoon, 9 April, the terms of surrender were agreed upon, and the War of the Rebellion was practically ended.

Sheridan's 'Personal Memoirs' (Vol. II.); Humphreys', 'The Virginia Campaign of 1864-5'; 'Official Records' (Vol. XLVI.); Powell, 'History of the Fifth Army Corps'; Walker, 'History of the Second Army Corps.'

E. A. CARMAN.

Farne, färn, or **Ferne** (fèrn) **Islands,** or **The Staples,** a group of islands in the North Sea, belonging to England; about two miles from Bamborough. Saint Cuthbert lived for some years on the largest island of the group and died here; ruins of the old abbey of which he was prior, of the ancient chapel, and of a peal tower still exist. These islands have been the scene of several disastrous shipwrecks, one of which, that of the Forfairshire steamer (1838), occasioned a display of remarkable heroism by Grace Darling, daughter of the keeper of one of the lighthouses. Another steamer, the Pegasus, going from Leith to Hull, was lost here in 1843 and 60 individuals perished. There are three lighthouses on the islands.

Farnese, Alessandro, ä-les-sän'drō fär-nā'sĕ, Italian general: b. Rome 1547; d. Arras, France, 3 Dec. 1592. He served his first campaign under Don John of Austria, and distinguished himself in the battle of Lepanto in 1571. In 1577 Philip II. ordered him to lead back the Spanish troops, which Don John had been obliged to dismiss from Flanders; and Don John dying that year, Alessandro was made governor. He recovered Maestricht and several other cities, and succeeded in reconciling the Catholic part of the insurgents to the Spanish government. The Protestants, however, formed the Union of Utrecht (1579), and called in the Duke of Anjou, a brother of Henry III. of France, to defend them. He appeared at the head of an army of 25,000 men; but Alessandro was constantly successful.

Farnese, Alessandro. See PAUL III., POPE.

Farnese Bacchus, a torso of Bacchus, an example of Greek sculpture of the 4th century B.C. It is in the National Museum at Naples.

Farnese Bull, a group of statuary representing Dirce, whom the sons of Antiope, her slave, are preparing to bind to the horns of the wild bull, which Dirce had intended to be the instrument of her vengeance upon Antiope. This is the most elaborate and dramatic, almost melodramatic, group to be found among the monuments of Greek art. It is the work of the vivacious Rhodian school, executed by Apollonius and Tyriscus. Having been transported to Rome, it was lost sight of for some hundreds of years. It was dug up in excavating the baths of Caracalla and in 1786 sent from the Palazzo Farnese to the National Museum at Naples.

Farnese, Elizabeth. See ELIZABETH FARNESE.

Farnese Hercules, a colossal statue, dating from the age of Hadrian, supposed to be a marble copy by Glycon of a bronze by Lysippus. It is an example of the turgidity and exaggeration which marked the decadence of Greek sculpture, wherein passion for scientific display of triumphs over all sense of ideal beauty, proportion and repose. Hercules is represented as leaning on his club, holding in one hand the Hesperidian fruit. The statue was dug up in the baths of Caracalla and passed through the Farnese family to the museum at Naples.

Farnese Homer, a bust of the Father of Poetry, which evidently belongs to the later period of Greek sculpture. It is in the National Museum at Naples.

Farnese Juno, a colossal head, a copy of a bronze original, representing Hera, "the Queen of Gods." It is in the National Museum, Naples.

Farnese, Minerva, The, an archaic statue of Athene, found at Velletri, at the foot of the Alban Hills, Italy. It is supposed to be a copy of the chryselephantine statue of Phidias, which stood in the main shrine of the Parthenon.

Farnham, färn'am, **Eliza Woodson Burhaus,** American philanthropist: b. Rensselaerville, N. Y., 17 Nov. 1815; d. New York 15 Dec. 1864. She traveled extensively; returned to New York in 1841; visited the State prison and lectured to the women convicts; and was matron of the Sing Sing State Prison for four years. She was the author of: 'California, Indoors and Out'; 'My Early Days' (1859); and 'Woman and Her Era' (1864), her most finished work.

Farnham, Ralph, American soldier: b. Lebanon, Me., 1756; d. Acton, Me., 1861. He was the last survivor of the Battle of Bunker

Hill, and the first settler in Acton. A public concert was given in his honor in Boston, October 1860, at which he was present. He was 104 years, 9 months, and 19 days old when he died.

Farnham, Roswell, American soldier and lawyer: b. Boston, Mass., 23 July 1827. He was graduated at the University of Vermont in 1849, admitted to the Orange County bar in 1857, and served as State attorney 1859–61. During the Civil War he was successively lieutenant of the 1st Vermont Regiment; provost-marshal of Newport News, Va.; and lieutenant-colonel of the 12th Vermont Regiment from enlistment to disbandment. He was governor of Vermont 1880–2.

Farnham, or West Farnham, Canada, in the province of Quebec; on the Yamaska River, the Canadian P., and the C. V. R.R.'s; about 40 miles southeast of Montreal. The chief manufactures are beet-root sugar, flour, and dairy products. Pop. 3,000.

Farnworth, färn'wėrth, England, a market town in Lancashire, three miles southeast of Bolton. It has a grammar school founded in 1715, and among its industrial establishments are paper-mills, iron foundries, cotton-mills, collieries, brick works, etc. The Bolton waterworks are at Farnworth. Pop. 25,927.

Faro, fä'rō, Portugal, a seaport on the south coast, capital of the district of Faro, on a bay protected by islands. It contains an old castle surrounded by Moorish fortifications. The town is well built, and has a fine square, a cathedral, and a number of good schools. There is a considerable trade, chiefly in oranges, dried fruits, oil, cork, wine, etc. Deposits of antimony and of salt are in the neighborhood. In 1722 and 1755 the city suffered great damage and loss of life from earthquakes. Pop. (1901) 11,908.

Faro, fā'rō, is a gambling game pure and simple. A pack of cards is fastened in a clip, face downward, so that one card at a time can be withdrawn. The spectators, before it is turned face upward, bet, some that it will be one kind of card in value, such as ace, king, queen, or jack; others that it will have this or that number of «pips» on it; others that it will be red or black. When all have been drawn but the last three the betting is restricted as to their order of appearance. Faro was introduced into France by the Venetian ambassador in 1674, in a form like bassette; but so many nobles were ruined by this game that Louis XIV. made a law against it. To elude this law it was called *pour et contre,* which gave rise to new prohibitions, to evade which the name Pharaoh was adopted. Faro is not a common game in the United States, although it is played at the large gambling houses in New York, Chicago, Long Branch, N. J.; Saratoga, N. Y., and on the Pacific coast. See GAMBLING.

Faroe, fā'rō, or **Faröer Islands** (that is «Sheep Islands»), a group of islands in the Northern Ocean, lying between lat. 61° 20' and 62° 25' N., about 280 miles southeast of Iceland, and about 190 miles northwest of the Shetland Islands; area 514 square miles. They belong to Denmark, and consist of about 20 islands, of which 17 are inhabited. The largest islands are Strömö (144 square miles), Osterö, Sandö, Suderö, and Vaagö. The islands generally present steep and lofty precipices to the sea; the surface rises toward the interior, Slattaratinde in Osterö being 2,894 feet high, while a pinnacle called the Witch's Finger is said to be 3,000 feet. The climate is milder than the latitude might indicate, but the weather is very variable; the annual rainfall is about 70 inches. Sheep and horses can winter in the open air. The soil is generally thin; barley is the only cereal that comes to maturity; turnips and potatoes thrive well. There are no trees, but plenty of excellent turf, and also coal. The wealth of the inhabitants is chiefly derived from fishing and the feeding of sheep. The feathers of sea-fowl form an important article of trade. Some horses and cattle are kept; the former are small, but strong and hardy. Thorshavn, in Strömö, is the seat of government, and the only town. These islands have belonged to Denmark since 1380. The inhabitants are Norse, and speak a Norse dialect in which there are a number of old ballads extant; the official language is Danish. They have a home government and are also represented in the Danish Parliament by two representatives elected by the people. Pop. (1890) 12,955. Consult: Jeaffreson, 'The Faroe Islands.'

Farquhar, Anna, American author (MARGARET ALLSTON), who became Anna Farquhar Bergengren on marrying, 26 Jan. 1900, Ralph Bergengren.

Farquhar. fär'kwär, **George,** Irish dramatist: b. Londonderry 1678; d. April 1707. About 1606–8 he went to London, where he commenced writing for the stage. His first production was 'Love and a Bottle,' performed with great success in 1699. In 1700 he added to his reputation by his comedy of 'The Constant Couple,' in which, under the character of Sir Harry Wildair, he exhibited a lively picture of the foppish fine gentleman of the end of the 17th century. In 1701 appeared 'Sir Harry Wildair,' a sequel to the former; and the following year he published a volume of 'Miscellanies.' 'The Inconstant, or the Way to Win Him,' appeared in 1703, and is among those which have kept possession of the stage. In 1706 appeared 'The Recruiting Officer,' one of his most popular plays; and this was succeeded by 'The Beaux' Stratagem,' which is reckoned his masterpiece. It is no mean testimony of the dramatic talents of Farquhar that three of his plays are still favorites with the public. His wit is genuine and spontaneous, and his characters are admirably supported, and drawn from nature. His plots excel in the arrangement of incidents and in unity of action. The libertinism of language and sentiment which his works exhibit cannot be defended; but it was the vice of the age rather than the writer, who was much less culpable in this respect than Dryden or Wycherley.

Farquhar, Norman von Heldrich, American naval officer: b. Pottsville, Pa., 11 April 1840; d. 3 July 1907. He graduated at Annapolis in 1859; was acting master in the African squadron engaged in the suppression of the slave trade 1859–61; and, during the Civil War, served in the North Atlantic blockading squadron. He commanded the Trenton when she was wrecked at Apia, Samoa, in 1889; became chief of the Bureau of Yards and Docks in 1890; and commandant of the Norfolk navy yard. He became rear-admiral in 1899, and retired 1902.

Farquharson, James, Scottish scientific writer: b. Coull, Aberdeenshire, 1781; d. 3 Dec. 1843. After obtaining his elementary education in the parish school at Coull he entered King's College, Aberdeen, whence he was graduated M.A. in 1798, receiving an appointment as schoolmaster that year at Alford. He later studied theology and was licensed to preach, but devoted all his leisure moments to the study of meteorology, botany, chemistry, zoology, and kindred branches. He wrote many papers for scientific journals, the most important of which are those on the aurora borealis, contributed to the 'Philosophical Transactions' of the Royal Society, the 'Edinburgh Philosophical Journal' (1823), and 'Philosophical Transactions' (1829–30). In 1836 he wrote for the last-named paper a remarkable treatise on the formation of ice at the bottom of running water. He also wrote: 'On the Nature and Localities of Hoar Frost' for the 'Transactions' of the Highland and Agricultural Society of Scotland for 1840. Among his religious publications are: 'On the Form of the Ark of Noah' (1831); 'A New Illustration of the Latter Part of Daniel's Last Vision and Prophecy' (1838); etc.

Farquharson, Joseph, Scottish painter: b. 1842. He inherited his love for painting from his father, who himself was an artist of some note. At the age of 13 he had become proficient enough in his art to send a picture, 'A Study from Nature,' to the exhibition of the Royal Scottish Academy at Edinburgh. When 16 years of age he entered the Board of Manufacturers School, Edinburgh, to pursue his studies under Hodder, and from there passed into the Life School. From 1859 to 1881 his pictures appeared in the periodical collections of the Royal Scottish Academy without a break. In 1880 he determined to perfect himself by a visit to the Parisian ateliers, and for several winters worked there under Carolus Duran. In 1900 he was elected an associate of the Royal Academy. Among his most noted pictures are: 'The Critics' (1866); 'Day's Dying Glow' (1873); 'Wonderland' (1879); 'The Babes in the Wood' (1880); 'Joyless Winter Days' (1883); 'Where Next?' (1883); 'The English Vintage' (1884); 'In Cairo' (1886); 'Under the Palm Trees' (1887); 'Summer Days' (1887); 'My Heart's in the Highlands' (1890); 'He Led Them Wandering O'er the Sandy Way' (1891); 'Leaving the Hills' (1892); etc.

Farquharson, Martha. See FINLEY, MARTHA.

Farr, Samuel, an eminent Scottish physician: b. Taunton, Somersetshire, in 1741; d. Upcott, near Taunton, 11 March 1795. He received his early education at the dissenting academy at Warrington, later pursued his medical studies at Edinburgh, and completed his course at Leyden University, whence he was graduated M.D. in 1765. He then settled in his native town, where he soon acquired a lucrative practice. It is for his medical writings that he is chiefly noted, his works showing the results of much original observation and extensive experience, and the majority of them are considered authorities in that line. They are 'An Essay on the Medical Virtues of Acids' (London 1769); 'A Philosophical Inquiry into the Nature, Origin, and Extent of Animal Motion' (London 1771); 'Aphorism de Marasmo, ex summis medicis collecti' (1772); 'Inquiry into the Propriety of Blood-letting in Consumption' (1775); 'The History of Epidemics by Hippocrates in seven books translated into English from the Greek, with Notes and Observations' (1781); 'A Preliminary Discourse on the Nature and Cure of Infection' (London 1781); 'Elements of Medical Jurisprudence' (London 1788); 'On the Use of Cantharides in Dropsical Complaints' ('Memoirs Medical,' ii. 132, 1789); etc.

Farr, William, English statistician: b. Kenley, Shropshire, 30 Nov. 1807; d. 14 April 1883. In 1837 he contributed an important article on vital statistics to Macculloch's 'Account of the British Empire,' and in the following year was appointed compiler of abstracts in the registrar-general's office. From 1839 he was connected with the Statistical Society, of which he was president 1871–2, and in 1885 there appeared a collection of Farr's statistical works entitled 'Vital Statistics,' comprising six parts treating respectively of population, marriages, births, deaths, life-tables, and miscellaneous matters.

Farragut, făr'a-gut, **David Glasgow,** American naval officer: b. Campbell's Station, Tenn., 5 July 1801; d. Portsmouth, N. H., 14 Aug. 1870. His mother, Elizabeth Shine, sprang from the Scottish family of MacIven. His father, George Farragut, was born on the island of Minorca in 1755. He was descended of an ancient and noble Spanish family, originally of Aragon but for 400 years of the Balearic Islands, where they held many positions of trust and responsibility. George Farragut came to America in 1776, espoused the colonial cause, and served creditably in the army, where he is alleged to have saved the life of Col. Washington at the battle of the Cowpens, and was afterward a sailing master in the navy.

Commander David Porter had been a shipmate of George Farragut. The latter had been transferred to the naval station at New Orleans and had bought a plantation on the Pascagoula River, where Porter visited him. The commander took a great fancy to David and with his father's consent — his mother being dead — practically adopted him with the intent of putting him in the navy.

David Farragut was warranted midshipman on 17 Dec. 1810, being less than 9½ years old. He had been nearly two years at school in Chester, Pa., when in August 1811 he was ordered to the frigate Essex, Porter's ship. He was in all the minor engagements before the famous Essex sailed on her unprecedented cruise to the Pacific. Such was the scarcity of officers that in June 1813 the little midshipman, not quite 12, was made prize master of the whaler Barclay. The English captain was sent along as adviser. He attempted to take things into his own hands, but Farragut, with a coolness and courage remarkable, retained command and brought his vessel into port.

He was slightly wounded in the terrific battle in which the Essex was destroyed by the Phœbe and Cherub. During a crisis in the action Porter actually sent this stripling to shoot a seaman who was reputed to be flinching from his gun. Farragut would have carried out his captain's orders if he had been able to find the man. In writing his report to the secretary of the navy Porter was compelled to say that Farragut was too young for the promotion he had earned by his gallant conduct.

After the war he remained in the service, taking advantage of such educational opportunities as were afforded him between and during his cruises. In the spring of 1819 he was appointed acting lieutenant of the brig Shark, being then 18 years of age. In 1823 cruised in the West Indies against Cuban pirates. He was married in September 1823 to Miss Susan C. Marchant of Norfolk. He was commissioned lieutenant 23 Jan. 1825. In 1828 witnessed the capture of San Juan de Ulloa by the French while in command of the Erie. Mrs. Farragut died 17 Dec. 1840, leaving no children. He was commissioned commander 9 Sept. 1841 and in December 1843 married Miss Virginia Loyall of Norfolk; by her had one son, who survives him. During the Mexican War commanded the Saratoga. Had no opportunity for distinction and became involved in a dispute with Commodore M. C. Perry, commanding naval forces. August 1854 established Mare Island Navy Yard, Cal.; commissioned captain 14 Sept. 1855. In general, his service between 1815 and 1861 was arduous and exacting and was diligently and successfully performed. His devotion to Union sentiment forced him to leave Norfolk in April 1861. Removed his family to Hastings-on-Hudson, N. Y., and at first vainly sought orders to active service.

In January 1862 was given command of the Western Gulf Blockading Squadron and ordered to open the mouth of the Mississippi River by taking New Orleans, which was defended by two forts, a river fleet of 17 vessels, including fireships and rams. The way up the river was barred by a boom. Farragut had a superb fleet of 6 heavy ships, 16 gunboats, 21 mortar vessels, and 5 smaller craft.

On 24 April 1862 the boom was broken, the forts passed, and the river defense fleet annihilated after a sanguinary and desperate battle. New Orleans surrendered four days later. The daring of the attack was only equaled by the skill with which it had been planned. Three vessels of the fleet failed to pass the forts. The Varuna was sunk, the flagship Hartford grounded in the midst of the action and was set on fire by a fireship pushed against her by the Confederate ram. She was got off in safety, however. As Farragut said, "They had a rough time."

Ordered to clear the Mississippi, in June 1862, Farragut passed the batteries at Vicksburg, but there being no land force there to coöperate with him he repassed the batteries and returned to New Orleans. Was commissioned rear admiral 16 July 1862, the first in the United States service. On 14 March 1863 attempted to take his fleet past the Confederate works at Port Hudson. Grant was then operating against Vicksburg. Farragut perceived that if he could get ships below Vicksburg he could prevent Confederate forces in that city from receiving supplies and re-enforcements from west of the Mississippi. Farragut's conception was strategically sound and brilliant. He boldly endeavored to carry it out.

Still in the Hartford, with a gunboat lashed alongside, he passed the batteries under a terrific fire. None of the other vessels succeeded in getting past. The Mississippi, of which George Dewey was the executive officer, grounded, was set on fire by Confederate shells, and burned to the water's edge. Farragut had only partially succeeded. Still the Hartford and the Albatross patrolled the river and practically cut all communication west of Vicksburg.

After the fall of Port Hudson he returned to New Orleans and on 1 Aug. 1863 sailed for New York to recuperate his health, impaired by his arduous labors. In January 1864 took command of the naval forces acting against Mobile. On the morning of 5 August entered the bay. The mouth was protected by two formidable forts, Morgan and Gaines. The narrow channel was obstructed by piling and lines of floating torpedoes. Farragut's fleet comprised 30 vessels, of which 8, including the flagship Hartford, were steam sloops-of-war of the first class. There were 4 monitors and 18 gunboats.

He attempted the passage with seven of his heavy sloops, each one lashed to a gunboat on its port side. The four monitors, the Tecumseh leading, were sent ahead, followed by the Brooklyn-Octorara couple, then the Hartford-Metacomet couple, and the other ships in succession. Farragut had ordered the column to pass close under the walls of Fort Morgan, through an opening left free of torpedoes for blockade runners.

At 7.45 A.M. the Tecumseh opened fire. The Confederate batteries did not reply until 20 minutes later. In Mobile Bay lay three gunboats and the ironclad ram Tennessee, Commodore Franklin Buchanan, a match, it was believed for the whole Union fleet. As Farragut approached the ram took position behind the torpedo line. In his eagerness to engage this redoubtable foe Craven on the Tecumseh disobeyed the admiral's order, and instead of passing through the opening headed for the Tennessee. He struck a torpedo and was blown up just as the Brooklyn got fairly under fire. Striking empty shell boxes thrown overboard from the vessels preceding it was thought she was in danger of torpedoes. She stopped and swung with her head toward the fort where none of her guns bore. The Confederates poured a rain of shot and shell upon her. The Hartford, coming up fast, nearly fouled the Brooklyn. The hesitant ships were bunched and made a target for every Confederate gun. The battle seemed lost.

Farragut, ascertaining that the Brooklyn had stopped for fear of torpedoes, ordered the Hartford to the head of the line, giving utterance to that immortal phrase: "Damn the torpedoes! Go ahead!" The Hartford passed the Brooklyn, narrowly escaping shoals to port and raced up the bay toward the Tennessee. It was now impossible to pass through the designated channel and Farragut drove the Hartford across the torpedo line. The example of the admiral put spirit into the Brooklyn and with the other ships she followed the flag. Fortunately no other torpedoes exploded and the whole fleet successfully passed the forts after a bloody and desperate battle.

The Tennessee had ranged along the Union ships and, immune to their fire, had shelled them at will. As soon as the passage had been made the Union gunboats were cast off from the frigates and the Confederate gunboats were captured or driven to the shelter of Fort Mor-

DAVID GLASGOW FARRAGUT.

gan. At 9 A.M. the Tennessee, with surprising gallantry, came up toward the Middle Ground to engage the Union fleet. To this battle Farragut was nothing loth. By his orders the wooden ships were hurled upon their antagonist. The Monongahela struck her a terrific blow at a right angle. The Lackawanna repeated the ramming tactics. The bows of the wooden ships were stove in to the water line. Both ships were raked by the Tennessee's rifles; their return broadsides doing no damage to the iron plating. The Tennessee made straight for the Hartford, which was bearing down directly upon her, bows on. One or the other ship would have been sunk had not the Tennessee swerved so that the Hartford struck her a glancing blow. The ram was now beset by all the vessels of the Union fleet which could get at her. She was rammed, hammered, and pounded. The monitors with their heavy guns were racking her from stem to stern. In the mêlée the Lackawanna rammed the Hartford, cutting her down to the water's edge. Finding his ship would still float Farragut ordered her again to ram the Tennessee. By this time the ironclad's smokestack had been shot away, the casemate was an inferno, the heavy battering had jammed the port shutters, shot had entered through the ports, not a gun could be fired, steam ran down in the boilers. She could neither fight nor fly, so she surrendered, after one hour of as fierce fighting as ever recorded.

During the passage of the forts Farragut had taken position in the main rigging in order to get above the smoke of the battle and be able to direct the maneuvers of the fleet the better. The quartermaster had passed a lashing around the admiral so that in case he should be wounded and lose his footing he would not fall to the deck.

In the battle Farragut should have led in the Hartford. It was only the urgent representations of his captains that made him take the second place. The battle was nearly lost by the gallant Craven's disobedience of orders and that it was finally won was due to the personal initiative of the admiral himself.

This completed his service during the war. He was 64 years old when he fought the battle of Mobile Bay. His health was quite broken. He was commissioned vice admiral 23 Dec. 1864; admiral 26 July 1866; sailed 28 June 1867 from New York in the steam frigate Franklin for an extended cruise in European waters, where he received such a welcome and was accorded such honors as have been tendered no other American save Gen. Grant. He returned to New York on 10 Nov. 1868, visited the Pacific Coast in the summer of 1869 and died 14 Aug. 1870. He was accorded the honor of a public funeral in New York 30 September, and was buried at Woodlawn Cemetery, Westchester County.

Farragut was a rather small man with broad shoulders and a well-knit, vigorous frame. His face was long with a broad high forehead and an aquiline nose. His complexion was dark and his eyes brown. He was a cultivated gentleman of the highest type, a most accomplished officer, a lion in bravery, a woman in gentleness. He was a simple-minded Christian of a high and humble type, a communicant of the Protestant Episcopal Church. A statue of him by Saint Gaudens stands in Madison Square, New York. One by Kitson in Boston; another by Vinnie Ream Hoxie in Washington. In the Church of the Incarnation, New York, is a mural tablet with a bas-relief of the admiral by Launt Thompson. Consult: 'Life and Letters,' by his son; Mahan, 'Admiral Farragut'; Barnes, 'Admiral Farragut'; Parker, 'Battle of Mobile Bay'; Brady, 'The Southerners.'

CYRUS TOWNSEND BRADY.

Farrakhabad. See FARUKHABAD.

Farrant, făr'ant, **Richard,** English composer: b. 1530; d. Windsor 1585. Very little is known of his history. He was a gentleman of the chapel royal for some time up till 1564, when he became organist and choir-master of St. George's, Windsor, but in 1569 he was again appointed to the chapel royal. His music is ecclesiastical, and is distinguished by purity, simplicity, tenderness, and elevation of tone. The anthems 'Call to Remembrance,' and 'Hide not Thou Thy Face,' composed by him, are well known and highly esteemed by lovers of good music. The exquisitely beautiful anthem, 'Lord, for Thy Tender Mercies' Sake,' has been attributed to him, but also to Thomas Tallis and John Hilton.

Farrar, Eliza Ware Rotch, American writer: b. Flanders, Belgium, 1791; d. Springfield, Mass., 22 April 1870. She married Prof. John Farrar of Harvard University. Her works include: 'The Children's Robinson Crusoe'; 'The Story of Lafayette'; 'The Youth's Love-Letters'; 'Congo in Search of His Master' (1854); and 'Recollections of Seventy Years' (1865).

Farrar, Frederick William, English clergyman and author: b. Bombay 7 Aug. 1831; d. London 22 March 1903. He studied at King William's College, Isle of Man, and Trinity College, Cambridge, having gained one of the college scholarships. He was ordained deacon in the Established Church 1854 and priest in 1857, and for 16 years was an assistant master at Harrow. From 1871 till 1876 he was head master of Marlborough College, resigning on his appointment as a canon of Westminster and rector of St. Margaret's. In 1883 he was appointed Archdeacon of Westminster, and in 1895 became Dean of Canterbury. From 1890 till 1895 he acted as chaplain to the House of Commons. Besides identifying himself with various social and philanthropic movements, he published many popular and able works of various kinds. In fiction he published: 'Eric, or Little by Little' (1858); 'Julian Home: a Tale of College Life' (1859); 'St. Winifred's'; 'Gathering Clouds: a Tale of the Days of St. Chrysostom' (1896); in philology: 'Origin of Language' (1860); 'Families of Speech' (1870); 'Language and Languages' (1878); etc.; and on theological and religious subjects: 'Seekers After God' (1869); 'The Witness of History to Christ' (1871); 'Life of Christ' (1874), a work which achieved extraordinary popularity; 'Life of St. Paul' (1879), also highly popular; 'Early Days of Christianity' (1882); 'History of Interpretation' (1885); 'Eternal Hope' (1888); 'Lives of the Fathers' (1889), a popular work: 'The Bible: Its Meaning and Supremacy' (1897); 'The Herods' (1897); 'The Life of Lives' (1899); 'Temperance Reform'; 'Texts Explained' (1899). In August 1885, he came to the United States, thereby realizing what he said had been one of the desires of his life. He remained in this country until the beginning of December, traveling, visiting friends and lecturing. He was a man of great eloquence, tremendous energy and was greatly beloved by all ranks, high as well as low. His most intimate American friend was Phillips Brooks.

Farrer, făr'ėr, **Henry,** American artist: b. London, England, 23 March 1844. He was the son of an English miniature painter, Thomas Farrer (1770–1850), and came to New York in 1863. He has painted largely in water colors but is widely known as an etcher also.

Farriery. See VETERINARY ART.

Farrington, Oliver Cummings, American geologist: b. Brewer, Maine, 9 Oct. 1864. He was graduated at the University of Maine in 1881; became lecturer on mineralogy in the University of Chicago in 1894, and curator of geology at the Field Columbian Museum in the same year. He has published: 'Meteorites'; and 'The Volcanoes of Mexico.'

Fars, färs, or **Farsistan,** fär-sis-tän' (ancient PERSIS), a province in the southwest of Persia, about 300 miles long by 250 miles broad. Its chief rivers are the Bandamir, the Sefid-rud, and the Mand; and it has several salt lakes, of which the largest is that of Bakhtegan. The most important products are grain, rice, fruit, wine, oil, cotton, tobacco, silk, cochineal, and attar of roses. The manufactures include woolen, silk, and cotton goods; and in these and other articles an active trade is carried on, chiefly with India. Many ancient ruins are scattered over the province. The capital is Shiraz, and the chief port is Bushire or Abushehr. About 30 miles north of Shiraz are the ruins of Persepolis, an ancient city. The people of this province are among the best preserved types of the Aryans. Pop. (estimated) 1,700,000.

Farsan (fär-sän') **Islands,** a group of two larger and several small islands on the east side of the Red Sea. The surface is diversified by hills composed of coral, and occasional valleys and plains. Pearl-fishing is here an important industry.

Farukhabad, fü-rook'ä-bäd, or **Farrakhabad,** fur-ruk-ä-bäd', India: (1) town in India, in a district of the same name in the northwest provinces; about two miles west of the Ganges, 90 miles west-northwest of Lucknow. It forms a single municipality with Fatehgarh, the civil headquarters of the district, situated three miles to the east. Pop. (1901), with cantonment, 67,338. (2) The district of Farukhabad forms part of the Agra division, and lies mainly along the western bank of the Ganges. Area, 1,720 square miles.

Farwell, Charles Benjamin, American merchant and legislator: b. Painted Post, N. Y., 1 July 1823; d. Lake Forest, Ill., 23 Sept. 1903. Having gone in 1838 to Illinois, he was there engaged in farming and government survey work until 1844, when he entered a mercantile career in Chicago. He accumulated a fortune in the dry-goods trade. In 1869 he was a national bank examiner, in 1871–6 and 1881–7 a representative in Congress. From 1887 to 1891 he was United States Senator, having been elected to fill the vacancy caused by the death of Gen. J. A. Logan. He was a figure of some prominence in both State and national politics.

Fasano, fä-sä'nō, **Italy,** a town in the southeast, near the Adriatic; 30 miles southeast of Bari. It is in the midst of an olive district, and there are numerous oil-presses in the town and neighborhood. The chief trade is in oil and wine. The cottages of many of the peasants have been made from the stone taken from old walls. Fasano was at one time a wealthy residential and commercial city. Pop. of the commune, 16,900.

Fasces, fas'ēz (Lat. *fascis,* a bundle), the most ancient insignia of the Roman magistrates, consisting of bundles of rods, usually birch, bound with which was an axe with projecting blade; used as a symbol of authority. The fascis was carried by an attendant known as a lictor. The number of lictors varied according to rank, and for a given dignitary frequently differed at different periods. Fasces were accorded quæstors in the provinces only.

Fascia, in anatomy, an animal tissue, consisting of dense connecting sheets or layers, of the nature of fibrous membrane, close and strong as tendon or ligament. The fascia in the economy of animal anatomy serves the purpose of confining within its proper area supporting as a sort of fulcrum, separating from one contiguous tissue, or attaching to another, some muscle, part or organ of the body. See the works on 'Anatomy' of Quain and Morris, in English; of Gegenbaur and Rauber, in German; and of Testut and Poirier, in French.

In architecture, a flat band, running horizontally across an entablature. The architrave in the Corinthian and Ionic orders is divided into three bands which are called fasciæ; the lowest being called the first fascia, the middle one the second, and the upper one the third. When there are only two fasciæ, they are called the upper and lower. See COLUMN; ENTABLATURE.

Fascination (Lat. *fascinare,* «to bewitch»). Various animals, such as toads, hawks, and notably certain varieties of serpents have been popularly invested with the power of controlling by their eyes the movements of intended victims. Such power has never been scientifically demonstrated, and supposed manifestations have generally been explained as paralysis through fear on the part of the victim. For an account of the belief in the evil eye in human beings, see SUPERSTITION.

Fascine, fă'sēn (Lat. *fascina,* a bundle of sticks), in fortification, a cylindrical bundle of faggots or brushwood used to form parapets, strengthen ramparts, elevate batteries, prepare temporary field defenses, and the like. They vary in size from 6 to 18 feet in length, 6 to 9 inches in diameter, and are bound with withes. Fascines dipped in pitch or other combustible matter are sometimes used in order to set fire to the enemy's lodgments or other works. In civil engineering fascines are used in making sea and river walls to protect shores subject to washing; or to collect sand, silt, and mud to raise the bottom and gradually form an island, either as a breakwater against inroads, or for purposes of cultivation, as in Holland.

Fasciolaria, a genus of mollusks. See FUSIDÆ.

Fashion, conventional usage in the matter of certain details of life, especially the changes and modifications of costume in civilized nations; mode or style in dress. Such variations of costume were unknown to most nations of the ancient world, and among the Romans only influenced the accessories of the toilet. The unchanging East is as unchanging in its dress as in everything else, and the fashions to which savage tribes uncompromisingly adhere remain unaltered for long periods. In some remote districts of European countries peasants still dress in the costume brought two or three hundred years ago by the local nobility from court, and the smock-frock of the English agricultural laborer is a relic of Saxon times. (For detailed history of the costumes of different periods, see article on COSTUME, and for certain principles underlying the subject, see DRESS.) Survivals in modern costume may sometimes be traced back to unexpected origins. With regard to the modern evening dress-coat we learn that it owes its peculiarities to its descent from the old-time everyday garment in which a man rode and worked. «The cutting away at the waist had once the reasonable purpose of preventing the coat skirts from getting in the way in riding, while the pair of useless buttons behind the waist are also relics from the times when such buttons really served the purpose of fastening these skirts behind: the curiously cut collar keeps the now misplaced notches made to allow of its being worn turned up or down.» It is said that the modern cylindrical hat is the indirect descendant of the Puritan steeple-crowned hat, carried across the Atlantic by the Pilgrim Fathers, thence again to France, when Benjamin Franklin and the young Republicans were the height of the fashion, and by the French manipulated into the hat which they have given to all the world. Certain striking features in vogue at different times in the dress both of men and of women have originated in the lack of bodily symmetry or in other physical defects in various monarchs or other leaders of fashion. Until the 19th century men's clothes were as delicate in color and as rich in material as women's. Pepys records in his diary how he had his wife's gowns cut up into waistcoats for himself. The uniforms of officials or of persons connected with public or special service, the judge's and the clergyman's robe and the student's cap and gown cannot be said to have had their origin in fashion; nor can the indication of political or religious opinions by peculiarities of dress, as among Puritans and Quakers, or as illustrated by colored cockades or other party emblems be called phases of fashion, yet fashion has been sometimes closely connected with political changes. Dress attained its highest point of significance in France during the last half of the 18th century, when it marks unmistakably the various stages of the Revolution. Rousseau's 'Emile and Nouvelle Héloïse' and Goethe's 'Werther' brought sentimentality into fashion; women's hair was dressed in *bandeaux d'amour* or *poufs de sentiment;* and Marie Antoinette and the ladies of her court sought to return to the simplicity of nature by masquerading in the Trianon attired as shepherdesses and milkmaids. The works of Montesquieu and Voltaire had created an admiration for England, and the courtiers of Versailles dressed themselves like English fox-hunting squires, while their wives and daughters got themselves up *á l'Anglaise* in coats with cuffs, collars, and facings, beaver-hats, and cravats. As the political turmoil increased, fashionable attire grew more and more eccentric and multiform, till at last republican institutions triumphed, and the women of France began to clothe themselves as like as possible those of Greece and Rome both in style and scantiness. They discarded costly materials, and shivered through the winter months clad in a few yards of muslin. Men wore a combination of antique and romantic costume invented by the painter David, which was finished off with Hungarian boots. At the present time the fashions for women in all civilized countries are set by Paris; for men, though not so exclusively, by London. One marked feature of the everchanging kaleidoscope of fashion is its tendency to revolve in cycles. Cycles of alternate luxury and simplicity have also distinguished all ages. Fashions change more quickly each decade, a fact due in great measure to increased facilities of communication, while the triumph of democracy is shown by their universal adoption by all classes. Consult: 'Nos Aieules,' translated as 'Ten Centuries of Toilet,' by Mrs. Cashel Hoey (1892). See also *Bibliography* of COSTUME.

Fashoda, fä-shō'dä, Egyptian Sudan town founded in 1867 by the Egyptian government, situated on the Bahr-el-Abiad or White Nile, 400 miles south of Khartum and about 70 miles northeast of the confluence of the Sobat River with the Nile. In July, 1898, it was occupied by a small French force, but some months later it was claimed by the British for Egypt. Ultimately the French force evacuated the town, which was then formally occupied by Sudanese troops.

Fassaite, fas'a-īt, the name applied to a pale green to pistachio or dark green variety of augite, or aluminous pyroxene (q.v.). It occurs in metamorphic, marly limestone in the Fassathal, Tyrol.

Fassett, fas'ĕt, **Cornelia Adèle Strong,** American artist: b. Owasco, N. Y., 9 Nov. 1831; d. Washington, D. C., 4 Jan. 1898. She studied in New York as well as in Paris and Rome, and from 1875 lived in Washington, where she painted portraits of many prominent statesmen. Her most important work is 'The Electoral Commission in Open Session,' including the portraits of some 200 persons.

Fassett, Jacob Sloat, American lawyer and capitalist: b. Elmira, N. Y., 13 Nov. 1853. He was graduated from Rochester University 1875, and was admitted to the bar 1878. He was State senator 1884–90 and was defeated as Republican nominee for governor in the year last named. He is the proprietor of the Elmira *Daily Advertiser,* and controls mining, banking, and other interests in the Western States and in Korea.

Fast and Loose, the name of a cheating game, also called «pricking at the belt,» which appears to have been much practised by English gypsies in the time of Shakespeare, and which is still played at fairs, races, and similar meetings under the name of «prick the garter.» The game consists in trying to pin to a table a belt or similar object so folded as to produce a misleading effect. The original name, in the phrase "to play fast and loose," has gone into the language to designate the conduct.

Fastenrath, Johannes, yō-hän'-nēs fäs'ten-rät, German poet and story writer: b. Remscheid 3 May 1839. A brief sojourn in Spain (1864) filled him with a permanent enthusiasm for the land and literature which inspired nearly all his life-work. He translated Juan Diana's comedy 'Receipt Against Mothers-in-Law'; and compiled a series of volumes which are less translations than transcriptions in the spirit of the originals — 'A Wreath of Spanish Romances'; 'Hesperian Blooms'; 'The Book of My Spanish Friends'; 'Voices of Christmas.' He has also published several works on the history of Spanish literature; and in Spanish, 'Passion-Books of a German-Spaniard,' a description of the Oberammergau Passion Play; and 'Walhalla and the Glories of Germany.' A volume of war songs dedicated 'To the German Heroes of 1870' is likewise his.

Fasti, fas'tī (Lat. *fasti,* lawful, *fas,* divine law, DIES, days), in ancient Rome, days on which the transaction of business before the prætor was legal, days on which court did not sit being *dies nefasti.* The name thence came to be applied to two sorts of registers or tables: (1) The *fasti sacri* or *fasti kalendares,* containing the calendars of the year. These were at first known only to the *pontifices,* or priests, who announced them to the people, and had thus a source of power and profit. In 304 B.C. Cn. Flavius, who had been secretary to the *Pontifex Maximus* Appius Claudius, Cæcus, exposed them to the people. (2) The *fasti annales* or *historici,* which formed a chronicle of contemporary events, containing the names of the chief magistrates of the year, and a series of the more remarkable events noted in the order of the days of their occurrence.

Fasting, or the practice of self-denial in regard to food and drink has obtained not only in Judaism and Christianity but in the religions of paganism: it is commended to Christians by the example of the prophets of Israel, Moses, Elias, and John the Baptist, and above all by the example and precepts of Christ and his apostles. Under the Mosaic law only one day was appointed to be observed annually by the whole people as a day of fasting — the Day of Atonement; but in addition to that solemn and divinely ordained fast numerous other fasts were enjoined by the Jewish traditional law. In the New Testament no stated days or seasons of fasting are prescribed, nor in the existing records of the Church's history do we find clear proofs of days or seasons of fasting being enjoined on the faithful till the beginning of the 4th century, though the practice of stated fasts was doubtless widely extended at an earlier period. In the strict sense of the word, fasting involves abstinence from all food and drink for a definite period; in the practice of the Church it means abstinence from food on a given day till a certain hour, till noon, or till sunset. The days and seasons of fasting in the Roman Catholic Church are: The 40 days of Lent; the Wednesdays, Fridays and Saturdays of the Ember weeks; the vigils or eves of certain festivals; the Wednesdays and Fridays of Advent. All Fridays throughout the year (except the Friday which happens to be Christmas Day), are "days of abstinence," that is, days on which the Church forbids the use of flesh-meat. Custom and church legislation have so modified the strict law of fasting, that besides the one meal a "collation," or light repast, is allowed in the afternoon or evening; and it is permitted to take at the usual hour of breakfast a small quantity of food. The days of fasting prescribed in the Anglican Book of Common Prayer are nearly the same as are observed in the Roman Catholic Church.

Fastnet Lighthouse. See CAPE CLEAR.

Fastolf, fas'tolf, SIR **John,** English soldier: b. Caister, near Yarmouth, about 1378; d. there 5 Nov. 1459. He saw much service in the French wars, and distinguished himself in the battle of Agincourt, the capture of Caen, the siege of Rouen, and other events. He was knighted about 1417, and made governor of the Bastile in 1420. In 1429 he was ordered to bring supplies to the English camp in front of Orleans, then in a state of siege. He went to Paris and obtained the provisions, but when returning was attacked at Rouvray by a French force much stronger than his own. In spite of this disadvantage, however, he succeeded in driving off the attacking party, mainly owing to the skilful manner in which he used barrels of herrings for defensive purposes. The battle is usually known from the last-mentioned circumstance, as the Battle of the Herrings. Some have charged him with cowardly behavior in the subsequent battle at Patay, and it is said that the Duke of Bedford deprived him of the Garter which had been conferred on him in 1426. This charge is, however, probably unfounded. In 1432 he was appointed English ambassador to the Council of Basel, and in 1441 he withdrew from the army. The 'Paston Letters' (q.v.) contain a long account of his later life in Norfolk, and show him to have been keenly bent on amassing a large fortune. He has been regarded as the prototype of Shakespeare's 'Sir John Falstaff.'

Fasts. Among the Jews fasts were numerous; founded on tradition, except that of the day of expiation, which was appointed by Moses. We find, however, fasting mentioned in the Old Testament. Herodotus says that the Egyptians prepared themselves by fasting for the celebration of the great festival of Isis. So in the Thesmophoria at Athens, and in the rites of Ceres at Rome, it was practised. Protestants consider that Christ and his apostles give no precept respecting fasting. It was probably, however, early practised by the Christians as a private act of devotion. The fast days in the Roman Catholic Church are: All the week days of Lent, beginning on Ash Wednesday, the Fridays in Advent, the Ember days, namely, Wednesdays, Fridays, and Saturdays following (1) the first Sunday in Lent; (2) Whitsunday; (3) the 14th of September; (4) the third Sunday of Advent; also the vigils of Pentecost, the Assumption, All Saints, and Christmas. When the vigil falls on Sunday, the fast is kept on the Saturday preceding. The days of abstinence (on which flesh-meat is not allowed) are all Fridays in the year and fast days. Illness, old age, and other causes may entitle a person to a dispensation from these regulations. The Protestant Episcopal Church appoints the following fixed days for fasting and abstinence, between which no difference is made: (1) the 40 days of Lent; (2) the Ember days, at the four seasons; (3) the three Rogation days before Holy Thursday; (4) every Friday except Christmas Day. The Church, however, gives no directions concerning fasting.

Fat-back, a name for the menhaden (q.v.), and for certain mullets, in allusion to the thickness of the dorsal adipose tissue.

Fat-bird, a name among sailors for the guacharo; and among sportsmen in New Jersey for the pectoral sandpiper.

Fata Morgana, fä'tä mor-gä'nä, a remarkable aërial phenomenon observed in the Strait of Messina, and other points in Italy and Sicily, and thus called because supposed to be the work of the fairy Morgana. Objects are reflected sometimes on the surface of the sea, and sometimes on a kind of aërial screen. An object has often two images, of which one is inverted.

Fatalism, the doctrine that all things are ordered for men by the arbitrary decrees of God or the fixed laws of nature. In theology it has given birth to theories of predestination, and in moral science to such systems as those of Spinoza and Hegel, and more recently to the philosophy of Herbert Spencer. It is carried out to its most pitilessly logical extreme among the Mohammedans, where everything that can happen is "kismet," that is, fated, or decreed by fate. See DETERMINISM; PREDESTINATION; WILL.

Fatality in Color. The color of a soldier's uniform is based upon a principle of fatality. Experience and statistics prove that men are hit in battle according to the color of their dress. Red is the most fatal; the least fatal is Austrian gray. The proportions are: red 12; green 7; brown 6; gray or blue 5.

Fategarh. See FATHIGARH.

Fatehpur. See FATHIPUR.

Fatehpur-Sikri, or **Futtipur-Sikra,** Hindustan, the site of an ancient town in the district of Agra. It was the favorite residence of the Emperor Akbar, who enclosed and fortified it, and the part of the palace containing the apartments of his celebrated prime-minister, Abu-Fazel, is still in good preservation. It is built of dark-red sandstone, in a fine style of Oriental Gothic, adorned with numerous pilasters and rich tracery and carvings, and crowned by two domes. In a tomb of elaborate workmanship, standing in the centre of an arcaded square and approached through a noble gate, several members of the royal family were interred.

Fates, Μοῖραι, *Moirai;* Lat. *Parcæ,* in ancient mythology, the inexorable sisters who spin the thread of human life. Homer mentions neither their separate names nor their number. The appellation *Clotho* (the spinner) was probably at first common to them all. As they were three in number, and poetry endeavored to designate them more precisely, *Clotho* became a proper name, as did also *Atropos* and *Lachesis.* Clotho means she who spins (the thread of life); Lachesis, the disposer of lots; Atropos, unalterable fate; so that all three refer to the same subject under different points of view. The first spins the thread, the second determines its length, and the third cuts it. In Homer and Hesiod they appear as goddesses of human fate and individual destiny, both in life and death. Among the lyric poets they seem to have a general power over events, and are always present where anything is to be divided. In the narrowest signification they are the goddesses of death, as of that destiny which closes the scene with all. In this capacity they belong to the infernal world, and are daughters of Erebus and Night. As goddesses of fate they are the servants of Zeus and the offspring of Zeus and Themis. The former genealogy is the more modern. As daughters of Zeus, they have a share in the decisions of fate, and are commissioned by him to execute his commands.

Father, Duties of a. See PARENT.

Father John, or **Father-of-Sickle,** translations of Arabic names for the common or sacred ibis of the Nile region. See IBIS.

Father Prout. See MAHONY, FRANCIS.

Fatherlasher, a small, ugly, cottoid fish, or bull-head (*Cottus bubalis*), from 8 to 10 inches in length. The head is large, and is furnished with several formidable spines. The fish is found on rocky coasts on both shores of the North Atlantic. On the Labrador coast it attains a large size, and is a considerable article of food.

Fathers of the Church, a title bestowed upon certain Church writers who stand preeminent as authorities in the interpretation of Scriptures, the ritual practice of the age they lived in, and the formulation of doctrine as accepted dogma. This authority is weightiest in the Apostolic Fathers (q.v.). Next come the Fathers of the Greek Church, such as Athanasius, Basil the Great, Gregory Nazianzen, and John Chrysostom. Parallel with these are Fathers of the Latin Church, among whom are Jerome, Ambrose, Augustine, and Gregory the Great. While these are the most important of the Fathers, the term is employed with some looseness and often made to include Greek writers like Origen, and Latin writers like Tertullian, whose speculations are sometimes charged with being unorthodox. In modern times, when the study of Christian doctrine has a tendency to become largely historical, the value of the patristic monuments is esteemed more highly than ever before in the progress of European learning.

Bibliography.— Patristic biography and literature: Smith and Wace, 'Dictionary of Christian Biography' (1888); Lightfoot, 'Apostolic Fathers' (1891); Migne, 'Patrologia,' containing Greek Fathers, 167 vols. and Latin Fathers, 222 vols. (1878). Translations into English: 'The Oxford Library of the Fathers,' 48 vols. (1885); Roberts and Donaldson, 'Ante-Nicene Fathers,' 24 vols. (1872); Schaff, 'Nicene and Post-Nicene Fathers,' 14 vols. (1886). Guides to the study of the Fathers will be found in the patristic manuals of Alzog (1888) and Nirschl (1885).

Fathigarh, Fategarh, Futtygurh, or **Futtigarh,** British India, a military district of Farnkababad (q.v.), three miles east of the city of that name. Pop. (1900) 12,400.

Fathipur, Fatehpur, or **Futtehpur,** British India, capital of the district of the same name, on the highway between Delhi and Calcutta, 70 miles northwest of Allahabad. It contains government buildings and a mosque. Pop. (1900) 20,000.

Fathom. See WEIGHTS AND MEASURES.

Fatigue, a condition of body or of mind brought about by excessive expenditure of energy. Fatigue may occur in any organ of the body as a result of overstimulation; but it is usual to speak of muscular fatigue and nervous fatigue, since the muscle-functions and nerve-functions may be more readily measured; and furthermore, when muscle-tissue and nerve-tissue become tired, this state is associated with certain conscious states that are more or less clearly understood. Fatigue of the sense-organs is included in nerve-fatigue. The sensations, if present, from fatigue, biologically considered, in other organs, such as liver-cells, kidney-cells, etc., are at present little known. The study of protoplasmic fatigue in plants and lower animals promises to open up much heretofore buried knowledge concerning these problems.

Fatigue in muscle results in the main from its excessive use, over and above its capacity to repair by physiological rest. The heart-muscle, while doing an immense amount of work, also does a great amount of resting. Less than one fourth of the time of the heart-cycle is used in contraction. Over three fourths is used in resting. The sense of fatigue is probably a distinct sensation from the organs of muscular sense conveyed to consciousness as a warning to stop excessive muscular activities. The causes leading up to the production of fatigue in muscles are by no means thoroughly understood. The present theory in popular belief teaches that fatigue is due to a form of poisoning of the nerve-end organs in the muscle, the poisonous materials being formed by the metabolism of the muscle — fatigue-stuffs, they have been named by physiologists. If these could be washed out of the muscle the sense of fatigue would go, the muscle-substance itself being apparently unaffected, and conversely, inactive muscles may be made to feel tired if the juices of tired muscles are made to circulate in their blood vessels. What these fatigue-stuffs are is yet undetermined with certainty. They are probably very complex, and probably include substances, like lactic acid and phosphates, that change the chemical reaction of the muscle-plasma, and most likely also a variety of other bodies.

Fatigue in sense-organs, such as taste, smell, touch, etc., may show itself by loss or change of the function. The taste is lost when the stimulation becomes excessive; so with smell and touch; and the same is true for the other sensations. A chemical basis for fatigue in the end-organs is probable, but little is known concerning this. Fatigue in the nerve-cell itself has been widely studied by physiochemical histological methods and certain changes in the nerve-cells seem correlated with fatigue-processes. These involve certain structures in the nucleus and in the stainable constituents (Nissl bodies) of the cells. Fatigue in the reflex arc, as, for instance, in the knee-jerk, is manifested by a steady diminution in the muscular response. Whether the reflexes are purely muscular or neuromuscular phenomena or not, similar changes take place in the end-organs and in the nerve-cells. Mental fatigue is probably closely correlated with the forms of fatigue in other nervous cells of the body. The cells of the brain are probably more complex, both histologically and chemically, than those in other parts of the nervous system, but the changes causing fatigue, and the results in modification of form, are probably of the same kind, if not of the same degree. Tire of the mental functions causes a sympton-complex that is very characteristic. See NEURASTHENIA.

A measure of fatigue-states is possible for most of the simpler muscle and nerve end-organ phenomena, but accurate methods of registering mental fatigue are much needed. School test-methods by which children are made to undergo psychological "stunts" are yielding some very valuable material, although vitiated by much amateurish pedagogical theorizing.

The measuring of the changes in the various reflexes, the nerve-end organs — sensations, perceptions, correlation of ideas, memory-images, etc.— constitutes an important part of a specialist's work in the study not only of normal psychology, but of the abnormal psychology of the insanities. Consult: Schäfer, 'Physiology'; Atwater, 'Digest of Metabolism Experiments'; Ziehen-Sommers, 'Psychophysiologische Methoden'; Verworn, 'General Physiology'; Mann, 'Physiological Histology'; 'American Journal of Psychology'; 'Psychological Review'; 'Educational Review.' See AUTO-INTOXICATION; INSANITY; MUSCLE-EXCITATION; NERVE-CELL; NERVE-FIBRE; NEURASTHENIA; SPECIAL SENSES.

Fatigue of Materials. See STRENGTH OF MATERIALS.

Fatima, fä-tē-mä, (1) The favorite daughter of Mohammed: b. Mecca, Arabia, about 606; d. Medina, Arabia, 632. She had three sons, Al-Hasan, Al-Husein, and Al-Muhsin. From the first two were descended the Saiyides. (2) In 'Aladdin,' the enchantress. (3) In the story of 'Bluebeard' the last wife, and the only one not murdered.

Fatimides, fat'i-mīdz, or **Fatimites,** fat'i-mīts (named from Fatima, the daughter of Mohammed and wife of Ali, from whom the founder of the dynasty described in the definition professed to have sprung), a race of Mohammedan kings, whose founder was Abu Abdallah Husein. Obeid Allah (909–33), subdued northern Africa from the Atlantic coast to Egypt, assumed the title Mahdi ("Leader of the Faithful"), established his capital at Mahadi and made himself independent of the Abbassic caliphs. The most important of the dynasty was Al-Mu'izz (955–78), who conquered Sicily and Egypt (972), transferred his court to the latter country, and founded Cairo. Al-Hakim (996–1021) persecuted Jews and Christians, and destroyed the Church of the Resurrection at Jerusalem (1009). His cruelties were a leading cause of the Crusades (q.v.). The dynasty included 14 caliphs, of whom Al-Adhid was the last (1171). Consult: Wüstenfeld, 'Geschichte der Fatimiden-Khalifen' (1881).

Fats. In chemistry, this class of substances was originally understood to include all those compounds of carbon, hydrogen and oxygen which leave a permanent, translucent grease-spot upon paper. In more recent times, however, it has been the custom to include only such bodies of this sort as admit of saponification. Our knowledge of the constitution of the fats is due in large measure to the labors of the French chemist Chevreul, who showed that they are mostly composed of glycerin, in combination with certain organic acids, prominent among which are oleic, stearic and palmitic acids. Fats may be extracted from animal tissues by heat, a temperature of 212° F. being sufficient. From seeds and other vegetable matters in which they occur they are commonly extracted by heating the ground-up tissues, and subjecting them to heavy pressure. As obtained by these methods, the fats often retain fragments of the original tissues in which they occur, as well as certain nitrogenous substances that come away with them. The nitrogenous matter may be removed by shaking the fluid fat (or oil) with sulphuric acid, and the fragments of tissue may be removed by dissolving the fat in ether, carbon disulphid, benzene, or light petroleum, and subsequently filtering the solution and recovering the fat by the evaporation of the solvent. The membranous particles that come away with the animal fats may also be removed by treating the fats with very dilute hydrochloric acid, which dissolves the membranous matter while leaving the fat unaltered.

The fats are decomposed when heated to 400° F., by the separation of their glycerin from the fatty acids with which it is combined. They may also be decomposed by saponification, — that is, by boiling them with aqueous solutions of the alkalis,— the decomposition, in this case, being due to the replacement of the combined glycerin by the alkali. The glycerin is thereby set free, and the resulting compounds of the alkali with the organic acids of the fats are known as soaps. (See SOAP.) The rancidity that develops in fats when they are kept for some time is due to the formation or liberation of certain volatile fatty acids, and it may be removed by boiling the fat with water (in which case the objectionable acids are volatilized), or by treating it with an aqueous solution of sodium carbonate (in which case the volatile acids are neutralized by the alkali, with the formation of their unobjectionable sodium salts).

As has been noted above, stearic, oleic and palmitic acids are the commonest of the acids that occur in fats. Their compounds (or "esters") with glycerin are known, respectively, as stearins, oleins, and palmitins, and are markedly similar in their general properties. The nature of these compounds may be sufficiently illustrated by taking stearin as an example. The formula of stearic acid is $H.C_{18}H_{35}O_2$ and that of glycerin is $C_3H_5(OH)_3$. If the two are heated together, they may combine in the following manner: $C_3H_5(OH)_3 + H.C_{18}H_{35}O_2 = C_3H_5(OH)_2.(C_{18}H_{35}O_2) + H_2O$, in which case the compound that is formed is known as "monostearin," or they may combine in this manner: $C_3H_5(OH)_3 + 2H.C_{18}H_{35}O_2 = C_3H_5(OH).(C_{18}H_{35}O_2)_2 + 2H_2O$, in which case the compound formed is known as "distearin" or, finally, they may combine thus: $C_3H_5(OH)_3+3H.C_{18}H_{35}O_2 = C_3H_5.(C_{18}H_{35}O_2)_3 + 3H_2O$, in which case the compound is called "tristearin." Similar reactions occur with oleic and palmitic acids. The compounds of these three acids that occur most commonly in fats are tristearin, triolein, and tripalmitin.

Fat Tissue, the deposits of fat in various parts of the animal organism. Fat is found in the young of vertebrate mammals from the moment of their birth, and under normal conditions continues to increase till puberty, when a marked diminution takes place. In middle life fat increases, and sometimes is acquired to gross excess. The chief use of fat in a proper quantity, is as a protective shield against atmospheric changes; it serves as a lubricant to several organs, and above all, it stores up the heat energy so essential to animal vitality.

Fatty Acids, monobasic acids formed by the oxidation of the primary alcohols. Such are formic and acetic acids, oleic, stearic and palmitic acids. Thus, when a fat is heated in combination with a stronger base than glycerin, such as potash or soda, the fatty acids leave the glycerin and combine with the metallic base, thus forming soap.

Fatty Compounds, or **Aliphatic Compounds**, in organic chemistry, are those compounds whose molecules do not include a closed chain of carbon atoms. (See AROMATIC COMPOUNDS.) The name "fatty" no longer implies any necessary relation to the fats, but it was originally given to the group because many of its earliest-known representatives occur in the animal or vegetable fats, or are related to them in a simple manner. The name "methane compounds" has also been proposed for the group, but it has not been generally adopted, although it is a particularly happy designation, since all of the compounds of the group are theoretically derivable from methane, CH_4, by addition or substitution. The fatty compounds may be subdivided, in a general way, into those that are "saturated," and those that are "unsaturated." Saturated compounds are those in which the atomic linkage is such that no more atoms can be attached to the carbon chain of the molecule, without causing it to split; and unsaturated compounds are those in which this condition is not fulfilled. For example, ethane, C_2H_6, has the structural formula

$$\begin{array}{ccccccc} & & H & & H & & \\ & & | & & | & & \\ H & — & C & — & C & — & H \\ & & | & & | & & \\ & & H & & H & & \end{array}$$

and it is therefore a saturated compound, because there is obviously no way to introduce more atoms without separating the carbon atoms, or removing one or more of the hydrogen atoms. If we introduce (say) the group CH_2 ("methene"), we must place it between the two carbon atoms, or between a carbon atom and one of the hydrogen atoms now attached to it. In either case the structural formula of the resulting compound (known as "propane," C_3H_8), is

$$\begin{array}{ccccccccc} & & H & & H & & H & & \\ & & | & & | & & | & & \\ H & — & C & — & C & — & C & — & H \\ & & | & & | & & | & & \\ & & H & & H & & H & & \end{array}$$

so that the new compound is also saturated. Ethylene (q.v.), C_2H_4, is an unsaturated compound, because carbon (according to the present theory) is always a tetravalent element, and a carbon nucleus containing two atoms of carbon is capable of fixing six atoms of hydrogen, as appears in the first of the foregoing structural formulæ. It is, therefore, usual to consider that in this case two valencies in the carbon nucleus satisfy each other, so that the structural formula for ethylene is

$$\begin{array}{ccc} H & & H \\ | & & | \\ C & = & C \\ | & & | \\ H & & H \end{array}$$

Here it is obviously possible to introduce two additional monad atoms or radicals, by breaking one of the two valencies uniting the carbon atoms, and attaching one of the monad atoms so introduced to each of the free ends of the valency so broken; the carbon atoms remaining constantly united by *one* of the bonds. If a pair of hydrogen atoms be introduced in this way, ethane is produced, as will be seen by inspecting the structural formula of that substance, given above. In acetylene (q.v.) C_2H_2, three bonds are commonly assumed to unite the two carbon atoms, so that the structural formula of this substance is $H - C \equiv C - H$. Acetylene therefore, is an unsaturated compound. Much attention has been paid to the theory of these double and triple bonds between adjacent carbon atoms, and it has been conclusively established (contrary to what might be naturally assumed) that a double or triple linkage between two carbon atoms constitutes a weaker bond than the single linkage. When, for example, an unsaturated compound is broken up by the action of powerful chemical reagents, it is almost invariably the double (or triple) bond that is ruptured. A quantitative study of the heat-energy liberated when compounds of carbon and hydrogen are burned also shows that the force required to break a double or triple bond is smaller than that required to break a single bond.

Although the fatty and aromatic groups of chemical compounds are differentiated so strongly that it is not easy to convert a representative of either group into a representative of the other one, such a transformation is nevertheless possible. Thus Berthelot showed that when acetylene gas is passed through a red-hot tube it is converted into benzene, naphthalene, and other members of the aromatic group; and an example of the opposite kind of transformation, in which an aromatic compound is converted into a fatty compound, is afforded by the formation of methyl chlorid, CH_3Cl, when hydrochloric acid gas is passed through boiling metaxylene, $C_6H_4(CH_3)_2$. It has been pointed out that there is probably much significance in the fact that the carbohydrates, which are the chief constituents of plants, are fatty compounds containing six (or a multiple of six) atoms of carbon; while the products obtained by the dry distillation of coal (that is, the fossilized remains of such plants), are chiefly aromatic compounds, in which six carbon atoms are united in the form of a "benzene nucleus." It is likely, in view of this fact, that most of the carbohydrates might be transformed into members of the aromatic group, by the prolonged action of great pressure and moderately high temperature.

Fundamental among the fatty compounds are three series of hydrocarbons, which contain only carbon and oxygen, and are known respectively as the paraffins, the olefines, and the acetylene series. The simplest member of the paraffin series is methane ("marsh gas"), CH_4, from from which the higher members are derived by successive additions of the group CH_2, as has already been illustrated in connection with the derivation of propane from ethane. The paraffins are very numerous, and many of the higher members of the series have been but little studied. As will be seen from their mode of derivation from methane, they all come under the general formula C_nH_{2n+2}, where n may have any value from unity up to a limit which probably exists, but is at present unknown. Isomeric forms of the paraffins are possible when n is greater than 3, and the number of such possible isomeric forms increases rapidly with n. Thus in the case of butane, C_4H_{10}, there can be but one isomer, while the compound $C_{13}H_{28}$, known as tridecane, is theoretically capable of existing in no less than 802 distinct forms. See ISOMERISM.

The olefine series of hydrocarbons begins with ethylene ("olefiant gas") C_2H_4, from which the higher members may be regarded as derived, just as before, by successive additions of CH_2. The general formula for the olefine series therefore is C_nH_{2n} and many isomers are known here also. The acetylene series, which has not been so thoroughly studied as the paraffins and the olefines, begins with acetylene gas, C_2H_2, and has the general formula C_nH_{2n-2}. See HYDROCARBONS.

Among the derivatives of the fatty hydrocarbons, the fatty alcohols and fatty acids require special mention. Alcohols, as a class, are considered under ALCOHOL. In general, they may be regarded as derived from the hydrocarbons by replacing one or more of the hydrogen atoms by an equal number of molecules of hydroxyl (OH). They are known as "monohydric," "dihydric," "trihydric," etc., according as one, two, three, etc., atoms of hydrogen are replaced in the original hydrocarbon. A vast number of monohydric alcohols are known, but the number of recognized dihydric alcohols (also known as "glycols") is far smaller. Five trihydric fatty alcohols are known, of which glycerin, $C_3H_5(OH)_3$, is the only familiar example; and only one fatty tetrahydric alcohol, erythrite, $C_4H_6(OH)_4$, is known, though a few that are still more highly hydrated have been prepared. The most important series of the monohydric fatty alcohols is that derived from the paraffin series of hydrocarbons, C_nH_{2n+2}, by the substitution of OH for H. The general formula for this series of alcohols therefore is $C_nH_{2n+1}.(OH)$; it includes methyl alcohol, ethyl alcohol, and, in fact, nearly all of the more familiar alcohols. The monohydric alcohols of the olefine series of hydrocarbons have the general formula $C_nH_{2n-1}.(OH)$, but they include only a single familiar example— allyl alcohol, $C_3H_5.OH$. Those of the acetylene series have the general formula $C_nH_{2n-3}.(OH)$, but they do not include any that are of importance save to the theoretical chemist.

The fatty acids are exceedingly numerous, and play a highly important part in the processes of animal and vegetable life. A complete classification of them cannot be here attempted, but three of the known series must be mentioned. The series derived from the paraffins has the general formula $C_nH_{2n}O_2$ and its members may be derived, by oxidation, from the alcohols of the paraffin series that contain the same number of carbon atoms. The best-known examples of this series are as follows:

Formic Acid	CH_2O_2
Acetic Acid	$C_2H_4O_2$
Propionic Acid	$C_3H_6O_2$
Butyric Acid	$C_4H_8O_2$
Capric Acid	$C_{10}H_{20}O_2$
Lauric Acid	$C_{12}H_{24}O_2$
Palmitic Acid	$C_{16}H_{32}O_2$
Stearic Acid	$C_{18}H_{36}O_2$
Melissic Acid	$C_{30}H_{60}O_2$

The alcohols corresponding to these acids have not all been prepared, but many of them have been, and the chemical deportment of the remaining members of the group leaves no doubt of their relation with the normal paraffins from which they are assumed to be derived. All of the foregoing acids are monobasic, containing but one atom of replaceable hydrogen; and these acids, together with the others that belong in the same series, are the ones to which the name "fatty acids" is often applied, by writers on chemistry, to the exclusion of all other organic acids. According to the definition of "fatty compounds" adopted above, however, all organic acids that do not contain closed carbon chains would appear to be logically included under this same title.

Two important series of acids are derived, by oxidation, from dihydric alcohols, or "glycols," of the paraffin series. The general formula for these glycols being $C_nH_{2n}(OH)_2$, the lactic acid series of acids is obtained from them by an oxidation which consists in the replacement of two atoms of hydrogen by one atom of oxygen. The general formula of the lactic acid series therefore is $C_nH_{2n}O_3$. Its most important members are as follows:

Carbonic Acid	CH_2O_3
Glycollic Acid	$C_2H_4O_3$
Lactic Acid	$C_3H_6O_3$
Hydroxybutyric Acid	$C_4H_8O_3$
Hydroxyvaleric Acid	$C_5H_{10}O_3$
Leucic Acid	$C_6H_{12}O_3$

Carbonic acid is included in this list on the hypothesis that it exists in aqueous solutions of the gas in the form $CO_2 + H_2O$. Except for carbonic acid, all the acids of the foregoing list are monobasic. For the reason why carbonic acid is not also monobasic, reference must be made to the more extended treatises on organic chemistry.

The oxalic acid series is derived from the glycol series, given above, by an oxidation which consists in the substitution of two atoms of oxygen for four of hydrogen. The general formula for this series of acids therefore is $C_nH_{2n-2}O_4$. The most important representatives are:

Oxalic Acid	$C_2H_2O_4$
Malonic Acid	$C_3H_4O_4$
Succinic Acid	$C_4H_6O_4$
Pyrotartaric Acid	$C_5H_8O_4$
Adipic Acid	$C_6H_{10}O_4$
Azaleic Acid	$C_9H_{16}O_4$
Sebacic Acid	$C_{10}H_{18}O_4$

The foregoing acids are all dibasic.

The carbohydrates constitute a large and important class of open-chain (or fatty) compounds. They all contain carbon, hydrogen, and oxygen, and are called "carbohydrates" because, like water, they contain precisely twice as many atoms of hydrogen as of oxygen, and can therefore be regarded as consisting merely of water and carbon. O'Sullivan's classification of these substances is given under CARBOHYDRATES; but the carbohydrates are more commonly divided simply into (1) glucoses (or hexoses); (2) saccharoses; and (3) amyloses. The glucoses comprise glucose (or dextrose), fructose (or levulose), galactose, and sorbose (or sorbinose); and they all have the empiric formula $C_6H_{12}O_6$. The saccharoses include cane-sugar, lactose, melezitose and maltose; they all have the empiric formula $C_{12}H_{22}O_{11}$, and are all derived by the union of two molecules of a glucose, with the elimination of one molecule of water. Their general formula may therefore be written $(C_6H_{11}O_5)_2O$, and they may be regarded as related to the glucoses in the same way that ether is related to alcohol. The amyloses include starch, glycogen, dextrin, cellulose, inulin, and the gums. They have the general empiric formula $(C_6H_{10}O_5)n$, but their structural formulæ are not yet known. Consult: Hjelt, 'Principles of General Organic Chemistry'; Allen, 'Commercial Organic Analysis'; Remsen, 'An Introduction to the Study of the Compounds of Carbon'; Richter, 'Chemistry of the Carbon Compounds'; Perkin and Kipping, 'Organic Chemistry'; Roscoe and Schorlemmer, 'A Treatise on Chemistry'; Meyer, 'Modern Theories of Chemistry'; Cohen, 'The Owens College Course of Practical Organic Chemistry'; Roscoe, 'Lessons in Elementary Chemistry'; and, in fact, any work on organic chemistry. See also, in this encyclopædia, ALCOHOL; HYDROCARBONS; ISOMERISM; SUGARS; and many other titles.

Fatty Degeneration. See DEGENERATION.

Fatuity, in present usage, synonymous with idiocy (q.v.). Foolishness or weakness of mind.

Fatwa, fut'wä, India, town Patna district, eight miles from Patna, at the junction of the Punpun with the Ganges. Fatwa is a place of great sanctity to Hindus. It is on the East Indian R.R., and has considerable trade. Pop. (1891) 10,919.

Faucigny, fō-sē-nyē, a district of France, department of Haute Savoie; area about 840 square miles. Belongs almost wholly to the basin of the Arve, and not more than one third of its surface is fit for culture. Pop. 102,000.

Faucit, fâ'sit, **Helen** (LADY MARTIN), English actress: b. London, England, 11 Oct. 1819; d. Wales 31 Oct. 1898. In 1851 she was married to Theodore (now Sir Theodore) Martin (q.v.). She made her professional début as Julia in the 'Hunchback' at Covent Garden in January 1836. She was at once successful, took a leading part in Macready's Shakespearean revivals, in the first representation of Lytton's plays, and in Browning's 'Blot in the Scutcheon' and 'Strafford.' As an interpreter of Shakespeare's heroines, Juliet, Rosalind, Portia, Beatrice, Imogen, Cordelia, and Lady Macbeth, she stood first among the actresses of her time. After her marriage she left the stage, appearing only at rare intervals for public or charitable purposes, as in Beatrice at the opening of the Shakespeare Memorial Theatre at Stratford. In 1885 she published a volume of delightful studies, entitled: 'On Some of Shakespeare's Female Characters' (Ophelia, Portia, Desdemona, Juliet, Imogen, Rosalind, and Beatrice).

Faulkner, fâk'nėr, **Charles James,** American lawyer: b. Berkeley County, Va., 1805; d. 1 Nov. 1884. He was admitted to the bar in 1829, set at various times in both houses of the Virginia legislature and was a member of Congress 1851–60. In the last-named year he was appointed minister to France. Returning to the United States in 1861 he was imprisoned on suspicion of disloyalty, in Fort Warren, Boston, but was exchanged the same year. He was elected to Congress from West Virginia in 1874.

Faulkner's Island, in Long Island Sound, belonging to Connecticut, and about four miles from the mainland. A lighthouse, still in use, was erected here some years ago.

Fault, in geology, any rock-crack or fissure with dislocation of the strata. The rock-movement may accompany the formation of the crack, or may come later, and the total movement may vary from a small fraction of a foot to many thousands of feet. Faults come by the same strains and stresses which make folds, the rocks breaking instead of bending; a brittle stratum may be faulted, while softer strata above or below may be only bent. The dip of a fault is the amount of inclination of the plane of fracture from the horizontal; the hade or slope is the complement of the dip, being the amount of inclination of the plane from the vertical. Thus the hade of a fault with a dip of 60° would be 30°. The rock-strata relatively dropped from the downthrow side; the upthrow side is opposite; the side of the fracture that overlies the other is the hanging wall; the underlying side is the foot-wall. The throw of a fault is the total vertical displacement; the heave is the total horizontal displacement — both measured in the plane of the dip. If a fault dips 45° the heave and throw are equal.

Faults are classified as normal and reversed. In a normal or gravity fault the hanging wall is on the downthrow side. In a reversed or thrust fault the hanging wall is on the upthrow side. Normal faults, as the strata occupy more space than before faulting, were produced by tension. Thrust faults are caused by compression, the beds on one side of the fracture being thrust past those on the other. As a rule thrust faults have lower dips than normal faults. The best examples of great normal faults in the United States are in the Arizona-Colorado plateau. Thrust faults are common in the southern Appalachian Mountains. Generally a fault-fissure is filled with more or less ground-up material from the dislocated strata, and the hanging and foot wall faces are grooved and polished, giving the appearance called slickensided.

It is obvious that faults are essentially surface phenomena; for with increasing depth and increasing pressure from above, rocks bend rather than break, and we can easily imagine a depth at which all rocks, while not truly molten, are plastic. See ESCAPEMENT; GEOLOGY; MOUNTAIN; ORE DEPOSIT.

Faun, fân (Lat. *Faunus,* from *favere,* to be favorable to), in Roman mythology, a Latin rural deity. See FAUNUS.

Faun of Praxiteles, a statue in the Capitoline Museum, Rome, known also as the 'Satyr of the Capitol. It is the best copy extant of an original attributed to the great Greek sculptor and furnished Hawthorne the title for his novel, 'The Marble Faun.' See PRAXITELES.

Fauna, fân'a̤, a term used by zoologists to signify the animals native to a special locality, region, or period of time, as the term "flora" is used by botanists. The term, when prefixed by certain words, is restricted to a more special usage, as "pisci fauna," the fishes of a certain region, etc. Geologists and palæontologists employ the term in a somewhat wider sense, as covering all the animals of a given region, during a geological period — the fossil remains of such animals being found in the successive layers of deposits formed during the entire period in which they lived.

Fauna, in Roman mythology, a Roman goddess, originally called Marica, but after her marriage with Faunus, named Fauna. She is sometimes identified with Cybele.

Faunce, Daniel Worcester, American Baptist clergyman: b. Plymouth, Mass., 3 Jan. 1829. He was graduated from Amherst College in 1850 and was ordained to the Baptist ministry in 1853. He has held various pastorates in New England and elsewhere and has published: 'The Christian in the World'; 'Words and Works of Jesus'; 'Words and Acts of the Apostles'; 'A Young Man's Difficulties with His Bible'; 'The Resurrection in Nature and Revelation'; 'Prayer as a Theory and a Fact'; 'Hours With a Skeptic'; 'Shall We Believe in a Divine Providence?'; etc.

Faunce, John, American naval officer: b. Plymouth, Mass., 25 March 1807; d. Jersey City, N. J., 5 June 1891. He entered the United States marine service as third lieutenant in 1837, and in 1845 was placed in charge of the Long Island and New Jersey life-saving stations. In 1858 he was made commander of the revenue steamer Harriet Lane, which, under his command, accompanied the naval expedition to Paraguay in 1858–9, and which in 1861 was one of the small fleet that was hastened to the relief of Fort Sumter, and was fired on by the Confederates at Charleston. After the War he was detailed to service in the life-saving department, in which capacity he did much toward its thorough organization and perfection.

Faunce, William Herbert Perry, American educator: b. Worcester, Mass., 15 Jan. 1859. He is a son of D. W. Faunce (q.v.). He was graduated at Brown University in 1880, and at the Newton Theological Seminary in 1884; held pastorates in Springfield, Mass., 1884–9, and New York 1889–99; was long a trustee of Brown and Rochester universities; lecturer at the University of Chicago; and preacher at Harvard University. He was made president of Brown University in June 1899.

Faunus, an Italian divinity, probably an ancient Italian king, who instructed his subjects in agriculture and the management of flocks, and was afterward worshipped as the god of fields and of shepherds. The festival of the Faunalia, held on 5 December, referred to the protection he exercised over agriculture and cattle. Fauna was his female complement. He was also worshipped as a prophetic divinity. As deity of the woods and of flocks and herds, he corresponds to the Greek Pan, and hence with his name became associated the attributes of the latter. The idea also arose of a plurality of fauns, like the Greek satyrs, who were represented with short horns, pointed ears, tails, and goats' feet, and to whom all terrifying sounds and appearances were ascribed. Readers of Hawthorne's 'Marble Faun' will remember the artistic use there made of the conception.

Fauque de Jonquières, fōk' de zhōn'kē-ār, Jean Phillipe Ernest, French admiral and mathematician: b. Carpentras, department of Vaucluse, France, 3 July 1820. He entered the navy in 1825 and became an admiral in 1874. He held important commands in Cochin China (1864) and as maritime prefect of Rochefort, and published several valuable mathematical treatises, including 'Système de courbes et surfaces algébriques d'ordre quelconque (1866).

Fauquier, fâ'kwėr, **Francis,** American colonial governor: b. about 1704; d. 1768. He succeeded Dinwiddie as lieutenant-governor of Virginia in 1758 and retained the office for the remainder of his life. Upon the passing of Patrick Henry's Stamp Act resolutions he dismissed the Virginia house of burgesses, opposed the Stamp Act Congress, and prevented the colony of Virginia from choosing delegates at the invitation of Massachusetts, by refusing to issue writs for summoning the house of burgesses.

Faure, François Félix, frän-swä fā-lēks fōr, French president: b. Paris 30 Jan. 1841; d. there 16 Feb. 1899 He was for a time a tanner in Touraine, but became a wealthy shipowner in Havre, and an authority on all questions concerning shipping, commerce, and the colonies. During the Franco-Prussian war he commanded a body of volunteers and gained the ribbon of the Legion of Honor. He entered the Assembly in 1881, served as colonial and commercial minister in the cabinets of Gambetta, Jules Favre, and Tirard, and as minister of marine in that of Dupuy. A moderate republican, he was elected president of the republic on the resignation of Casimir-Perrier in 1895.

Fauriel, Claude Charles, clōd shärl fō-rē-el, French historian: b. St. Etienne, France, 21 Oct. 1772; d. Paris 15 July 1844. He published: 'History of Southern Gaul under its German Conquerors' (1836); 'The Origin of the Epic of the Middle Ages' (1833); 'History of Provençal Poetry' (1846); and 'Dante and the Origin of the Italian Language and Literature' (1854); etc.

Faust, or **Fust, Johann,** yō'hän foust or foost, German goldsmith of the 15th century and one of the persons to whom the invention of printing is generally ascribed. It is, however, doubtful if he did more than advance money to Gutenberg, who had previously made some attempts with movable types at Strasburg. The third person concerned was Schöffer, who married the daughter of Faust, and who is allowed the honor of having invented punches and matrices for casting types, by means of which this grand art was carried to perfection. The first fruits of the new process, that is a work printed with cast letters, appears to have been the 'Mazarin Bible,' or 'Forty-two-line Bible' (the latter name from the number of lines in a column) completed about 1455. Another early work was 'Durandi Rationale Divinorum Officiorum,' published by Faust and Schöffer 1459, followed a year or two after by the 'Catholicon Johannis Januensis'; after which, in 1462, succeeded the 'Latin and German Bible,' so much sought for by those fond of early specimens of typography. There is reason to believe that Faust died of the plague in 1466, as the name of Schöffer alone is found in the books printed after that time at Maintz. Owing, perhaps, to a similarity of name some of the noted deeds of Dr. Faust have been ascribed in popular German legends to the printer.

Faust, foust, or **Faustus,** fâs'tus, **Doctor John,** German magician: b. Knittlingen, Suabia; d. Staufen 1540. The facts of his life have almost entirely disappeared amid the legends and fables in which they have become wrapped up. He appears to have been a charlatan and adventurer who traveled from place to place, putting himself forward as a physician, alchemist, and astrologer, and as a great magician and enchanter. At Würzburg he professed that he could perform all the miracles that Christ performed, and at Wittenberg claimed that the successes of the imperial troops in Italy had been brought about by his magical powers. Among the credulous and ignorant he naturally found many to put faith in his claims and at last his name became associated with a whole series of marvels. The first literary work of which he is the subject was published at Frankfort in 1587, by Johann Spies, and professes to narrate the 'History of Dr. John Faust, the Far-famed Enchanter, and Professor of the Black Art.' Enlarged editions soon appeared and the book was translated into English (about 1588), Low German, Flemish, and French. In it we find most of the famous stories associated with Faust's name; how he sold himself to the devil for a period of 24 years; how, by the aid of the fiend Mephistopheles, he and his attendant and pupil, Wagner, were able for this time to enjoy all sorts of sensual delights and to travel about performing the most marvelous exploits, and how at last, when the end of the fatal compact arrived, after a night of dreadful tempest, his body was found almost torn limb from limb, lying on a dunghill at the village of Rimlich, near Wittenberg. It was on the English translation of Spies' book that Marlowe's great tragedy, 'The Tragical History of Doctor Faustus,' was based. In 1599 the legendary history of Faust appeared at Hamburg in a new form, as narrated by G. R. Widmann, a zealous Lutheran, always eager to draw a lesson from the events with which he deals. In an altered edition of this by Pfitzer (1674) we first find the germ of Goethe's Margaret, the maiden whose fate is so tragically connected with that of Faust, in the great drama of the German poet. In the second part of his 'Faust,' Goethe has attempted a poetical solution of the legend. Through all vicissitudes he leads Faust to a point where at last he experiences the feeling of perfect happiness in devoting his intellectual faculties to the promotion of the welfare of his kind. Then he has attained the end which he has pointed out to Mephistopheles as the object of all his longings, and is removed from this life, not, however, to be lost, but to be saved by love, the «ever-womanly» that «leads us on high." Goethe's famous poem attempts to show that man's longing after knowledge may lead him into many errors and failings, but cannot destroy his better nature. Goethe's 'Faust' was arranged for the stage by W. G. Wills in 1885. Among the various English translations of Goethe's 'Faust' that by Bayard Taylor is one of the most important. The well-known opera of 'Faust,' by Gounod, was first produced in 1859.

Fausta, Flavia Maximiana, flā'vi-a mak"-sim-i-ā'na fâs-ta, Roman empress: d. probably 326 A.D. She was a daughter of the emperor Maximianus Herculius and was married to Constantine the Great 307.

Faustina, Annia, an'i-a fâs-tī'na (surnamed JUNIOR) Roman empress: d. near Mount Taunis, Asia Minor, 175 A.D. She was a daughter of Annia Galeria Faustina (q.v.) and was married to Marcus Aurelius 145 or 146 A.D. She was noted for her profligacy.

Faustina, Annia Galeria (surnamed SENIOR), Roman empress: b. about 104 A.D.; d. 141. She was the wife of Antoninus Pius, and like her daughter, the wife of Marcus Aurelius, was famed for her licentiousness.

Fava, Onorato, ō-nō-rä'tō fä'vä, Italian author: b. Collobiano, Piedmont, 7 July 1859. He has published: 'Early Follies' (1881); 'Against the Majority' (1888); a novel, 'To the Country of the Stars' (1889); a juvenile, 'Our Life' (1885); 'The Departure of Hannibal' (1891); and various other works, showing as much originality as versatility.

Favara, fä-vä'rä, Sicily, town, four miles southeast of Girgenti. It has mines of sulphur, tourmaline, and alum, and nearby are marble-quarries. Pop. of the commune (1901) 20,400.

Favart, Charles Simon, sharl sē-môn fä-vär, French dramatist: b. Paris, France, 13 Nov. 1710; d. there 18 May 1792. His very youthful poem, 'France Freed by the Maid of Orleans,' won the prize of the floral plays; and at 24 he was writing successful comedies. These and his operettas number about 150 (his wife, Marie Justine Bénédicte Duronceray, 1727–72, being his constant collaborator), and are for the most part pretty and realistic scenes of love in the country; but some of them are amusing drolleries like the mediæval fabliaux. His most celebrated compositions are: 'Annette and Lubin'; 'The Village Astrologer'; 'Ninette at Court'; 'The Three Sultanas'; 'The Englishman at Bordeaux.' His 'Memoirs and Correspondence' (3 vols. 1808) is of great value for the history of literature.

Favenc, fav'ĕn, **Ernest,** Australian journalist and author: b. London 1846. He was a pioneer in Queensland 1865–79 and since 1888 has been active in journalism. He has published: 'The History of Australian Exploration'; 'Tales of the Austral Tropics'; 'The Secret of the Australian Desert'; 'Marooned in Australia'; 'The Moccasins of Silence'; 'Tales from the Sydney Bulletin.'

Faversham, fav'ėr-sham, **William,** American actor: b. England 17 Feb. 1868. After serving for a time in the English army in India he went on the stage in 1887 and the next year came to the United States. Since then he has been prominent under Frohman's management in New York.

Faversham (ancient FAVERSFIELD), **England,** a municipal borough and seaport in the county of Kent, 45 miles east-southeast of London. It contains three suburbs, and has a handsome cruciform church, good schools, a literary institute, and reading-rooms. The chief manufactures are gunpowder, Roman and Portland cement, bricks, and beer; it has large oyster fisheries. It was once the seat of the Saxon kings, and, in 930, Athelstane held here a Witenagemot, or great national council. There are still in existence remains of the abbey built by King Stephen, in 1147, for the Benedictine monks. The tomb of the king, who was buried in the abbey, is now pointed out in the parish church. In 1688 James II., when trying to escape to France, after the landing of William of Orange, was seized at Faversham and sent back to London. Later he succeeded in reaching France. Pop. (1901) 11,290.

Favignana, fä-vēn-yä'nä (ancient ÆGUSA or ÆTHUSA): (1) an island of the Ægades group in the Mediterranean, eight miles from the west coast of Sicily; area, 11 square miles. There is a fine bay on the east on which stand the town and fortress of San Leonardo. San Giacomo, the principal place, is on the north coast. The island has several quarries, and extensive tunny and anchovy fisheries, in the produce of which, and in sheep, goats, and poultry, it has a flourishing export trade. Pop. 5,149. (2) A town of the same name is on the north side of the island.

Favositidæ, fav-ō-sit'i-dē, a palæozoic family of fossil tabulate corals, having the septa and corallites distinct, and little or no true cœnenchyma. The corallites are uniformly prismatic, tall and united by their thick walls, which are perforated by large pores, representing aborted buds. The typical forms (*Favosites*) make large compact masses, taking an important part in the formation of Silurian and Devonian limestones. About 10 genera are indicated by the numerous and widely distributed species.

Favre, Gabriel Claude Jules, gä-brē-el clōd zhül fävr, French politician: b. Lyons 21 March 1809; d. Versailles 20 Jan. 1880. He took an active part in the Revolution of July 1830, studied law, and after distinguishing himself at the Lyons bar came to Paris in 1835, where he became famous as a defender of political prisoners. On the outbreak of the revolution of 1848 Ledru-Rollin made him secretary to the ministry of the interior. He was a leader of the party of opposition to the President Louis Napoleon; and after the *coup d'état* (1851) retired from political life for six years, till in 1858 his defense of Orsini for the attempt on the life of the emperor again brought him forward. From this time he again became an active leader of the Republican opposition to the emperor. On the fall of the empire he became vice-president of the government of national defense and minister of foreign affairs, and as such conducted the negotiations for peace with Prince Bismarck. But though he showed great energy and was very eloquent, his operations both in the matter of the armistice and the peace showed a lack of skill and judgment. He was elected to the French Academy in 1867. He was author of: 'Rome et la République Française' (1871); 'Gouvernement de la Défense Nationale'

(1871–5); ‹Conférences et Discours Littéraires› (1873); ‹Discours Parlementaires› (1881); ‹Mélanges Politiques› (1882).

Favre, Louis, French engineer: b. Chêne-Bourg, near Geneva, 29 Jan. 1826; d. 19 July 1879. In 1872 he gained the contract for constructing the Saint Gothard tunnel within the space of eight years, an engineering feat which he accomplished shortly before his death.

Favus. See RINGWORM.

Fawcett, fâ'set, **Edgar,** American novelist and poet: b. New York 26 May 1847; d. London, England, 1 May, 1904. He was graduated at Columbia College in 1867. His novels are: ‹Purple and Fine Linen› (1873); ‹A Hopeless Case› (1880); ‹A Gentleman of Leisure› (1881); ‹An Ambitious Woman› (1883); ‹Rutherford› (1884); ‹Tinkling Cymbals› (1884); ‹The Adventures of a Widow› (1884); ‹Social Silhouettes› (1885); ‹The Confessions of Claude› (1886); ‹The House at High Bridge› (1887); ‹Miriam Balestier› (1888); ‹A Man's Will› (1888); ‹Olivia Delaplaine› (1888); ‹A Demoralizing Marriage› (1889); ‹Fabian Dimitry› (1890); ‹A New York Family› (1891); ‹An Heir to Millions› (1892); ‹Women Must Weep› (1892); ‹A Mild Barbarian› (1894); ‹Outrageous Fortune› (1894); etc. His poetical works include: ‹Short Poems for Short People› (1872); ‹Fantasy and Passion› (1877); ‹Song and Story› (1884); ‹Romance and Revery› (1886); ‹The New King Arthur›; ‹Songs of Doubt and Dream› (1889).

Fawcett, Henry, English political economist: b. Salisbury, England, 26 Aug. 1833; d. Cambridge 6 Nov. 1884. An accident which deprived him of sight early in life did not prevent his attainment of distinction as postmaster-general in 1880. He was the author of ‹Manual of Political Economy› (1863); ‹The Economic Position of the British Laborer› (1865); ‹Pauperism: Its Causes and Remedies› (1871); and ‹Protection and Reciprocity› (6th ed. 1885), in which the liberal theory of the younger Mill is carried to its logical extreme; ‹Labor and Wages› (1884). See Stephen, ‹Life of Henry Fawcett› (1885).

Fawcett, Millicent Garrett, English political economist: b. Aldeburgh, Suffolk, 11 June 1847. She was married to Henry Fawcett (q.v.) 1867. She has taken a very prominent part in many movements relating to women, more particularly in that for obtaining the parliamentary franchise for them. In 1889 she was elected president of the Women's Unionist Association. Her published works include: ‹Political Economy for Beginners› (1870); ‹Tales in Political Economy› (1875); ‹Janet Doncaster,› a novel (1875); ‹Some Eminent Women of Our Time› (1889); and ‹Life of Queen Victoria› (1895); ‹Life of Sir William Molesworth› (1901). With her husband she published in 1872 a volume of ‹Essays and Lectures.›

Fawkes, fâks, **Guy,** English conspirator: b. York, England, 1570; d. Westminster 31 Jan. 1606. He enlisted in the Spanish army in the Netherlands, where he was found by Winter, one of the Roman Catholic conspirators, and with him returned to England in 1604, after agreeing to assist in the Gunpowder Plot (q.v.). He passed under the name of Johnson, as servant to Thomas Percy, another conspirator, and was placed to lodge in the house next to the Parliament House. After collecting the necessary combustibles, Fawkes worked his way into the coal cellar under the House of Lords, and after storing it with gunpowder, etc., was appointed to the dangerous duty of firing the mine. The government having had timely information of the detestable plot, the House of Lords and its cellar were searched, and Fawkes found secreted amid some casks of gunpowder, 5 Nov. 1605. He was at once arrested, and suffered death at Westminster with several of the other conspirators.

Fay, Amy, American lecturer on music: b. Bayou Goula, La., 21 May 1844. She has published ‹Music Study in Germany.›

Fáy, fī or fäy, **Andreas,** Hungarian author: b. Kohány, Zemplin, Hungary, 30 May 1786; d. Pest 26 July 1864. Till the appearance of Kossuth on the scene (1840) he was the foremost leader at Pest of the Opposition party; thereafter he took no considerable part in politics, but promoted many important national enterprises. His volume of poems, ‹New Garland› (1818) established his fame as a poet, but his admirable prose ‹Fables› (1820) attained a far wider popularity. Among his dramatic works are the tragedy, ‹The Two Báthorys› (1827); and several comedies, the most notable being ‹The Old Coins; or the Transylvanians in Hungary› (1824), and ‹The Hunt in the Matra› (1860). His social novel, ‹The House of the Béltekys› (1832), and a number of short stories, entitle him to a place among the great masters of Hungarian prose.

Fay, Charles Ernest, American educator and mountain climber: b. Roxbury, Mass., 10 March 1846. He was graduated from Tufts College in 1868 and has been professor of modern languages there from 1871. He has been several times president of the Appalachian Mountain Club and has been very prominent in the development of mountaineering in the Canadian Rocky and Selkirk mountains. He has lectured publicly on literary and geographical themes, and has edited ‹Appalachia› from 1879.

Fay, fī, **Joseph,** German painter: b. Cologne 10 Aug. 1813; d. Düsseldorf 27 July 1875. His art education began in the Düsseldorf Academy and was continued in Paris where he turned his attention to historical painting. His first picture, ‹Samson and Delilah,› was exhibited in his 27th year. He painted a series of frescoes in the Council Chamber at Elberfeld, in which was portrayed the history of Germany from the destruction of the Varian legions. The work is creditable. His fertile pencil produced among other pictures, ‹Thisbe›; ‹Romeo and Juliet›; ‹Gretchen.› He later on paid some attention to genre, depicting scenes in Italian life, reminiscences of travel in the peninsula. Felicitous conception, brilliant coloring and dextrous brush work are conspicuous in his productions.

Fay, Theodore Sedgwick, American writer: b. New York 10 Feb. 1807; d. Berlin, Germany, 17 Nov. 1898. He was eminent in periodical journalism for years. To this period belongs his book, ‹Dreams and Reveries of a Quiet Man› (1832). He served with ability in the United States diplomatic service, and wrote: 'Norman Leslie' (1835); and 'The Countess Ida' (1841), tales; 'Ulric' (1851), a poem; 'The Three Germanys' (1889); 'Great Outlines of Geography'; 'History of Switzerland,' etc. After 1861 he lived in Berlin.

Fayal, fī-âl'; Port. fī-äl, one of the Azores group, in lon. 28° 41' W.; lat. 38° 31' N. It is circular in form, about 10 miles in diameter; area 69 square miles. It rises abruptly from the sea, and the centre is about 3,000 feet in height. The climate is temperate all the year. Volcanic eruptions have taken place, but not in recent years. The soil is fertile, and the principal productions are wheat, maize, flax, fruits. Hunting small game, fishing, raising cattle, and agriculture are the leading occupations. Horta or Orto is chief port. Pop., estimated, 40,000.

Faye, Hervé Auguste Etienne Albans, ār-vā ō-güst ā-tē-en äl-bän fā, French astronomer: b. St. Benoit du Sault, France, 5 Oct. 1814; d. Passy, near Paris, 4 July 1902. He studied at the Ecole Polytechnique, where he was professor of geodesy in 1848–54, and later of astronomy, and at the Paris Observatory. He discovered the comet which bears his name in 1843; became rector of the university academy of Nancy in 1855; inspector-general of higher education in 1877; and was made chevalier of the Legion of Honor in 1843, and promoted to grand officer of the Legion in 1889. He wrote several books on astronomical subjects, among which are: 'Sur l'Origine du Monde'; 'Cours d'Astronomie Nautique.'

Fayence. See FAÏENCE.

Faye's Comet, discovered by the astronomer Faye 22 Nov. 1843. It has returned in the years 1851, 1858, 1865, 1873, 1880, 1888, and 1895. See COMETS.

Fayerweather, făr'-wet'h ėr, **Daniel B.,** American merchant and philanthropist: b. Stepney, Conn., 1821; d. 1890. He was long prominent in the leather business in New York and bequeathed some $5,000,000 to educational and charitable institutions, which is now (1904) being contested and the case is pending in the United States Supreme Court.

Fayette, fā-et', Iowa, town in Fayette County; on the Chicago, M. & St. P. R.R.; 65 miles northwest of Dubuque. It is the seat of Upper Iowa University, a Methodist Episcopal institution founded in 1857, one year after the settlement of the town. It is located in an excellent agricultural section. Pop. (1900) 2,717.

Fayette, Mo., city, county-seat of Howard County; 105 miles east by south of Kansas City; on the Missouri, K. & T. R.R. It is the seat of the Howard Payne College for women, founded in 1844, and the Central College, coeducational, founded in 1857, both under the auspices of the Methodist Episcopal, South, Church. It is in an agricultural section and the trade and industries are connected with agricultural products. Pop. 2,708.

Fayetteville, fā-et'vil, Ark., city, county-seat of Washington County; on the St. Louis & S. F. R.R.; in the Ozark Mountains. It is a well-known summer resort and is called the "Athens of Arkansas." Fayetteville is a fruit centre for northwestern Arkansas. It is the seat of the Arkansas Industrial University. Its chief manufactories are a foundry, flour-mills, large wagon factory, and fruit evaporating establishment. Pop. (1900) 4,061.

Fayetteville, N. C., city, county-seat of Cumberland County; on Cape Fear River, and on the Central Coast Line, and the Cape Fear and Y. V. R.R.'s, 120 miles south of Wilmington. It contains a high school, military academy, a State colored normal school, a bank, and several newspapers. It has manufactories of edge tools, carriages, wooden-ware, flour, turpentine, cotton, etc. On 22 April 1861, the Confederates seized the United States arsenal at this point. Gen. Sherman occupied the town 11–14 March 1865, and destroyed the arsenal. Pop. (1900) 4,670.

Fayetteville, Tenn., town, county-seat of Lincoln County; on the Elk River, the Nashville, C. & S. L. R.R.; 180 miles east of Memphis. The Fayetteville Collegiate Institute and Dick White College are located here. The manufactures are flour, lumber, wagons, and dairy products. Pop. (1900) 2,708.

Fayum, or **Fayoum,** fī-oom', **The** (Egypt. *Phiom,* "marsh-land"), a province of Egypt, consisting of a nearly circular basin or oasis, about 30 miles in diameter, or 840 square miles in area, sunk beneath the level of the Libyan desert, about half a degree south of Cairo, and connected with the Nile valley by a narrow pass, through which an ancient canal flows. This canal is the Bahr-Yûsuf, or "Joseph's stream," so named after Saladin, who restored an original construction of the Theban Pharaohs, which pours the fertilizing water which renders the Fayyûm one of the most productive parts of Egypt. The irrigation was anciently regulated by a large reservoir, called Lake Mœris (q.v.), described by the Greeks as a work of extraordinary hydraulic ingenuity, and the overflow now forms the large sheet of brackish water, 35 miles long, known as the Birket-el-Karn, which marks the eastern boundary of the oasis. The site was identified by Linant near the modern capital Medinet-el-Fayyûm, though other sites have been proposed by Cope, Whitehouse, and others. On the banks of Lake Mœris was the famous Labyrinth, probably built by Amenhemhat III., and reckoned one of the wonders of the world. The remains of this vast palace are seen in the ruins of numerous chambers near the brick pyramid of Hawâra. The capital of the Fayyûm was Crocodilopolis, afterward named Arsinoë, after the queen of Ptolemy Philadelphus, near the site of which is the modern chief town (pop. 31,262). Fidimin is a picturesque village in the Fayyûm. Recent explorations by Petrie and others have revealed more interesting remains of antiquity in the province than had formerly been suspected. The Fayyûm abounds in fruit, oranges, peaches, pomegranates, olives, figs, grapes, etc., and is famous for roses and other flowers. The inhabitants are chiefly agriculturists and fishermen. The fields yield splendid crops of cereals, besides rice, cotton, sugar, flax, and hemp. Pop. 160,000. Consult, for an account of excavations in the Labyrinth, the ruins at Hawâra, etc., Flinders Petrie, 'Hawâra and Arsinoë'; Brown, 'The Fayyûm and Lake Mœris' (1893).

Fea, fē, **Allan,** English antiquarian: b. 25 May 1860. He was employed in the Bank of

England 1880–90, and is the author of: 'The Flight of the King'; 'Secret Chambers and Hiding Places'; 'King Monmouth.'

Fealty, loyalty; faithful adherence; true service or duty to a superior lord, the obligation which bound the tenant, especially in feudal times. Fealty, suit of court, and rent, were conditions upon which the ancient lords granted their lands to feudatories; it being stipulated that they and their heirs should take the oath of fealty or fidelity to their lord, which was the feudal bond (*commune vinculum*) between lord and tenant; that they should do suit, or duly attend and follow the lord's courts, and there from time to time give their assistance, by serving on juries either to decide the property of their neighbors in the court baron, or correct their misdemeanors in the court leet; and lastly, that they should yield to the lord certain annual stated returns, in military attendance, in provisions, in arms, in matters of ornament or pleasure, in rustic employments (prædial labors), or (which is *instar omnium*), in money, which provided all the rest; all of these services being comprised under the one general name of redditus, return, or rent. The right of fealty still exists in England, but is exacted only from copyholders. It lasted in the United States for a short time after the Revolution, but soon became obsolete.

Fear, apprehension of approaching evil, danger or harm; solicitude, dread, terror. The term fear is also used in the sense of respect for and obedience to authority, especially as these take the form of awe and reverence toward the Supreme Being, with due regard to his law and word. The operation of fear on the mind is often, if uncorrected, attended with the most serious consequences, especially where sickness is present or disease threatened. On many persons the influence of fear is far more serious in its effect than the worst form of any dreaded malady. In epidemic diseases the terror they inspire is often as fatal as the infection — paralyzing the system, and robbing the body of the natural elasticity of its nervous stamina, and the mind of the buoyancy of hope, making victims of those who, from age and strength, had the best probability of escaping. Fear is a mental poison, and the most potent of all antagonists to health and medicine; it is often fatally active in the morbid developments which result in various forms of insanity; and as faith has cured more diseases than physicians ever prescribed for, so fear is more destructive than the worst physical malady. In the conflicts of the modern business world, especially in monetary centres, its contagion now and then breaks out in fright which imperils the fortunes of individuals, or a people's financial stability, as a country's cause is sometimes lost through panic striking its armies in battle. Recent psychology finds in fear one of its most important subjects for analysis and definition; and the physician, the teacher, the moralist, and the sociologist all deal with it as an element calling for special study and control in the development of the individual and of society at large. See EMOTION.

Fearnley, fĕrn'lĭ, **Carl Frederik,** Norwegian astronomer: b. Frederikshald 19 Dec. 1818; d. Christiania 22 Aug. 1890. He studied at Bonn and Königsberg, returning to Christiania and becoming professor of astronomy at the university 1857, and director of the observatory 1861. He was appointed head of the geodetic survey of Norway 1876. He published: 'Zur Theorie der terrestrischen Refraction' (1884); 'Zonenbeobachtungen der Sterne zwischen 64° 50′ und 70° 10′ nördlicher Deklination' (1888).

Fearnley, Thomas, Norwegian landscape painter: b. Frederikshald 27 Dec. 1802; d. Munich 16 Jan. 1842. He studied at Copenhagen, and subsequently traveled much, painting excellent landscapes, most of which are in England. Among his works are: 'Copenhagen' (1823); 'View of the Marumelf'; 'Justeldas Glacier'; 'Duck Shooting'; 'Romsdalhorn'; 'Grindelwald Glacier'; 'Waterfall and Sawmill'; 'Sorrento'; 'Madumsfall'; 'Castelmare'; 'Moonlight'; 'Gravius Fjord'; 'View in Norway'; 'Labrofos Waterfall.'

Feast, a festival, banquet, solemnity, holiday, etc. Almost every religion has had its solemn feast-days. The ancient Greeks and Romans had them, as well as the Jews and modern Christians. According to the Old Testament, several festivals among the ancient Jews were divinely appointed, the first and most ancient of which was the Sabbath, or seventh day of the week, commemorative of the creation. The Passover was instituted in memory of their deliverance out of Egypt, and of the favor of God in sparing their first-born when those of the Egyptians were slain. The feast of Pentecost was celebrated on the 50th day after the Passover, in memory of the law being given to Moses on Mount Sinai. The feast of Tents or Tabernacles was instituted in memory of their fathers who dwelt in tents for 40 years in the wilderness; and all Israel was obliged to attend the temple and dwell eight days under tents. These were their principal feasts, but they had numerous others — the feast of Trumpets, the feast of Expiation or Atonement, the feast of the Dedication of the Temple, etc.

In the Christian Church no festival appears clearly to have been instituted by Jesus or his apostles, yet Christians have always celebrated the memory of his resurrection, and numerous other feasts were introduced at an early period. At first they were only appointed to commemorate the more prominent events in the life and death of Christ, and the labors and virtues of the apostles and evengelists; but martyrs were soon introduced, and by the 4th century the number of feasts had very greatly increased. Many of the festivals were instituted on pagan models, and were characterized by rites similar to those which the pagans observed.

Feasts are either movable or immovable. Immovable feasts are such as are celebrated constantly on the same day of the year, among them being Christmas Day, Circumcision, Epiphany, Candlemas or Purification, Lady-day or the Annunciation, All-Saints', All-Souls', and the days of the several apostles, as St. Thomas, St. Paul. Movable feasts are those which are not confined to the same day of the year. Of these the principal is Easter, which gives law to all the rest, all of them following and keeping their proper distances from it; as Palm Sunday, Good Friday, Ash Wednesday, Sexagesima, Ascension Day, Pentecost, and Trinity Sunday. Besides these, which are general, there are others which are local or occasional, enjoined by the magistrate, or voluntarily set on foot by the people, such as, in this country, Independence Day, celebrated annually on the 4th of July, and Thanksgiving Day, also held every year on a day set apart by the President for the occasion. See FOOLS, FEAST OF.

Feather, one of the elastic horny dermal outgrowths of the skin, forming plumage, the characteristic covering of birds. See PLUMAGE.

Feather Bunch-grass (*Stipa viridula*), a rather slender grass, one to three feet high, growing in the Rocky Mountain region and on the foot-hills and mesas, from British Columbia southward to Mexico and westward to the coast. On good land, under irrigation, this grass attains the height of three feet or more, and is by far the most valuable of the *Stipas* for hay. The leafy culms are terminated by a narrow, many-flowered panicle of comparatively small and rather short-awned spikelets. The seed may be easily gathered. The callus at the base of the fruiting glume is short and barely pointed and not produced into a long, very sharp, spur-like extension, as in porcupine-grass.

Feather-star, a crinoid of the existing family *Comatulidæ,* which is composed of several genera of highly developed crinoids which differ from the "stone-lilies" and other existing forms in swimming freely as adults instead of being rooted by a stalk. The headquarters of the family is in the Malayan seas, but several species occur on the American and British coasts, and one of the latter, the rosy feather-star (*Antedon rosaceus*), has been exhaustively studied, contributing greatly to our knowledge of the whole group. It has the general characteristics of a crinoid (q.v.), and when young is attached to a long stalk, but when full grown drops off and thereafter creeps and swims about, back downward, by means of five pairs of radiating arms which are so fringed and flexible that they look like feathers. These arms expand about three inches.

Feather-tracts, one of those regulated spaces where feathers grow on the body of a bird, the arrangement of which is various and characteristic of groups. This regular distribution of feather-growths is known as "pterylosis," and the study of it as "pterylography." Pterylosis is further treated under PLUMAGE.

Feather-wings, a plume-moth (q.v.).

Feathering Float, the paddle or float-board of a paddle-wheel, so arranged as to turn on an axis to present its broad side to the water at its lowest submergence, but to turn its edge to the water in entering and emerging.

Feathering Paddle-wheel, a wheel whose floats have a motion on an axis, so as to descend nearly vertically into the water and ascend the same way, avoiding beating on the water in the descent and lifting water in the ascent.

Feathering Propeller, an invention of an Englishman, Maudslay, in which the vanes of the propeller screw are adjustable, so as even to be turned into the plane of the propeller-shaft and offer no resistance when the vessel is under sail and the propeller not used.

Feathers, Artificial. Artificial feathers and flowers have long been made in the United States. It is probable that the industry was brought here by French immigrants, who had fled from their own country. The number of French people here was soon increased by those who had come hither from the island of Haiti. It was necessary that these strangers should live, and one of the first industries they took up was artificial flower and feather making. Artificial feathers serve as cheap decorations for ladies' hats and bonnets. As long ago as 1840 there were 10 manufacturers in this line in New York. No separate enumeration of these products appears in the early census returns, but the quantity demanded increased greatly. Within the past few years a great change has taken place; feathers now being used as trimming on ladies' dresses, and as boas and collars. New York is the principal seat of the industry.

Featherstonhaugh, fĕth'ėr stŭn hâ, **George William,** English traveler in America: b. 1780; d. Havre, France, 28 Sept. 1866. He made geological surveys in the West for the United States War Department 1834–5, and was appointed by Great Britain a commissioner to determine the northwestern boundary between Canada and the United States, under the Ashburton-Webster treaty. He was the author of numerous technical reports and papers, including the 'Geological Report of the Elevated Country Between the Missouri and Red Rivers' (1834); 'Excursion Through the Slave States' (1844); 'Canoe Voyage to the Minnesota' (1847), etc.

Feb'iger, John Carson, American naval officer: b. Pittsburg, Pa., 14 Feb. 1821; d. Londonderry, Pa., 9 Oct. 1898. He was appointed a midshipman in the navy in 1838; became commander 16 July 1862, and was assigned to the steamer Kanawha of the Western Gulf blockading fleet. On 5 May 1864, while in command of the Mattabeset, of the North Atlantic fleet, he participated with the little squadron under Capt. Melanchthon Smith in defeating the Confederate ram Albemarle, in Albemarle Sound, N. C., and was commended for his bravery and skill in that engagement. He was promoted rear-admiral 4 Feb. 1882.

Febrifuge, feb'rĭ-fūj, a remedy used to destroy or mitigate fever. When rise in temperature was considered the important feature of a disease and this single symptom was considered apart from the rest of the life history of a disease process, febrifuges were much in use, but at the present time, when a disease is considered in its entirety rather than from its purely symptomatic manifestations, this class of remedies has fallen into a position of less prominence. High temperatures are now looked upon as evidences of a reaction in the body in its struggle with disease and, unless excessive and prolonged, should not necessarily be interfered with. A temperature of 103° to 104° F. is rarely harmful, but when the thermometer registers above 104° F. it is advisable to reduce it, for which purpose cold packs and cold sponging are among the best means. Such drugs as the newer synthetics, acetanilid, antipyrine, phenacetine, salol, and other like derivatives, and aconite, diaphoretics, etc., are still much in use; but only within restricted limits may they be said to be curative. In malaria, the high temperature being due to the development of large numbers of parasites in the blood, quinine, by killing the parasites, destroys the fever. See ANIMAL HEAT; ANTIPYRETICS; FEVER.

Febrile. See FEVER.

Febro'nianism (from Justinus Febronius, a pseudonym assumed by John Nicolaus von Hontheim, archbishop of Trèves), a system of doctrines antagonistic to the admitted claims of the Pope, and asserting the independence of national Churches, and the rights of bishops to unrestricted action in matters of discipline and church government within their own dioceses. Febronianism is opposed to Ultramontanism (q.v.), and developed into the Old Catholic Movement.

February. See CALENDAR.

February Revolution, The, in French history, the revolution of 1848, which brought about the fall of the July monarchy. See FRANCE.

Febvre, Alexandre Frédéric, äl-ek-sŏṅ-dr frā-dā-rik fevr, French actor: b. Paris 1835. He made his début at Havre, subsequently appearing in Paris at the Beaumarchais, the Porte St. Martin, the Gâité, the Odéon and the Ambigu theatres. He is very successful in comedy, among his principal creations being Clarkson in 'L'Etranger'; Kobus in 'L'Ami Fritz,' and Bourdon in 'Les Corbeaux.' He went to London with a company in 1877, making his farewell appearance at the Théâtre Français in 1893, "touring" the principal cities of Europe in 1894, and was sent to the United States to study the drama here in 1895. He is the author of 'Album de la Comédie Française' (1880); 'Au bord de la Scène' (1889); 'L'Heritage de Mme. Naudin' (1893); 'Le Journal d'un Comédien' (1896); 'La Clef des Champs' (1899).

Fécamp, fā käṅ, France, town in the department of Seine-Inférieure, at the mouth of a stream of the same name, 23 miles northeast of Havre. It stretches along a narrow valley enclosed by two parallel ranges of hills, and has a parish church, which originally belonged to the famous abbey of Fécamp, a school of hydrography, manufactures of cotton, linen, and woolen goods, sugar works, tanneries, building yards, several mills, a valuable fishery, and a spacious harbor with deep water and good anchorage. The town was celebrated for its herring fishery as early as the 13th century. Pop. (1901) 15,380.

Fechner, Gustav Theodor, goos täf' tā'ō dōr fĕн'nĕr, German philosopher: b. Gross Särchen, Prussia, 19 April 1801; d. Leipsic 18 Nov. 1887. His works on purely scientific topics, 'Elements of Psychophysics' (1860), and 'Text Book of Experimental Physics' (1828) among them, and his 'Three Motives and Grounds of Faith' (1863), are well known, while under the name of "Doctor Mises" he wrote various popular humorous and satirical works, notably, 'A Proof that the Moon is Made of Iodine' (1821); 'Comparative Anatomy of the Angels' (1825); and 'The Little Book of Life After Death' (1836). See Kuntze, 'Gustav Theodor Fechner, ein deutsches Gelehrtenleben' (1892); Lasowitz, 'Gustav Theodor Fechner' (1896).

Fechter, Charles Albert, sharlz äl-bār fĕн-tē' French actor: b. Belleville, near Paris, 23 Oct. 1824; d. Quakertown, Pa., 4 Aug. 1879. He made his first public appearance in 1840 at the Salle Molière, in Paris, after which he went to Florence with a dramatic company as leading juvenile. Subsequently he apeared as Seide in Voltaire's 'Mahomet,' in 1844; as Valère in Molière's great comedy; and as Armand Duval in 'La Dame aux Camelias.' In 1860 he went to London, where he presented 'The Corsican Brothers,' 'Don César de Bazan,' and 'Hamlet.' In 1870 he came to the United States and played to crowded houses, being especially popular in 'The Count of Monte Cristo.'

Fecial. See FETIAL.

Feckenham, fek'ĕn-am, or **Fecknam,** fek'-nam, **John de,** English Roman Catholic prelate: b. Feckenham Forest, Worcestershire, about 1516; d. Wisbech, Cambridgeshire, 1518. He served as chaplain to Bell, the bishop of Worcester Bell, and to Bonner, the bishop of London, going as a prisoner to the Tower upon Bell's fall 1549. Upon Queen Mary's accession to the throne he was made chaplain 1553, later becoming dean of St. Paul's. He held a conference with Lady Jane Grey shortly before her execution. He became abbot of Westminster 1556, and was a member of Queen Elizabeth's first parliament, the last mitred abbot to appear in that legislative body. Being active against the Reformation he was again sent to the Tower 1560, was released 1574, but kept under surveillance as long as he lived.

Fecundation. See PREGNANCY.

Federal Courts. See COURT.

Federal Government. Federal is derived from the Latin *fœdus*, a league, treaty, covenant, and applied to the governments of confederations, which consist of several united sovereign states, as, for instance, the United States, Switzerland, Mexico, etc. The degree to which such states give up their individual rights as sovereign bodies may be very different. Thus, the old German empire was a confederation under a head, and yet one member of it might wage war with another; while the different members of the United States have given up, among other things, all political power in so far as it relates to foreign affairs. In the Swiss Confederation the different members are allowed to conclude treaties with foreign powers, if they are not expressly prohibited by the constitution. It must be observed that every confederation has not a federal government, because sometimes a confederation consists merely of a union between a number of states, not stricter than a treaty, defensive and offensive, between two states, as, for instance, the former Germanic Confederation. See GOVERNMENT.

Federal Hall, New York city, originally the City Hall, built 1699 in Nassau Street, to replace the old Dutch "stadt-huys." It had a cage in front for criminals, a whipping-post, and stocks. On the assumption of independence it was made the State capitol; the Declaration was read in front of it, and Washington was inaugurated on its steps 4 March 1789. In 1836 it was torn down, and the sub-treasury building erected on its site.

Federal States, states united by a federation or treaty which, binding them sufficiently for mutual defense and the settlement of questions bearing on the welfare of the whole, yet leaves each state free within certain limits to govern itself. Switzerland and the United States are examples of this political constitution. Such a union or confederation is sometimes known as a federacy. The term federation indicates centralization in government, while confederation is used where state sovereignty is stronger.

Federalist, The (1787-8). When the text of the Constitution was published in New York 27 Sept. 1787, the opposition was at first overwhelming; the State held too advantageous a position, as general gatekeeper of the commerce of her neighbors and able to support herself by levying customs duties on them, to surrender it. Unless New York ratified the Constitution, there could be no Union; and New York certainly would not ratify it as things stood. Alexander Hamilton, therefore, induced James Madison and John Jay to unite with him in publishing a series of anonymous essays to defend the new instrument and urge its absolute necessity; Gouverneur Morris was asked to join, but declined. From 27 Oct. 1787 to 2 April 1788, 77 essays were published in the semi-weekly 'Independent Journal' of New York, entitled, 'The Federalist,' and signed first "A Citizen of New York," then "Publius." Eight more were added when they were collected in book form. Their influence was enormous not only in New York, where they greatly aided the final ratification by two votes, but elsewhere the essays circulated extensively in pamphlet form; they were so acute and massively learned in their exposition of the true intent of the Constitution, that even the courts have accepted them as authoritative comments in doubtful cases; and they are held by all the civilized world as among the noblest storehouses of political philosophy in existence, a classic text-book of political science. The exact authorship is matter of debate. Jay certainly wrote 5; Hamilton's son claimed 63 for his father and 3 for him and Madison jointly, leaving the latter 14, but Madison in 1819 claimed 29 for himself alone, leaving Hamilton 51. John Fiske thinks Madison's 29 much the most valuable for constitutional exposition; the Hamiltonians can claim half of them. There are many editions; the best is Paul Leicester Ford's indexed edition of 1898. In John C. Hamilton's of 1875 he has a long essay on the authorship.

Federalists, or **Federal Party,** in the United States; in power 1789–1801; died nationally about 1817, locally about 1823; the lineal ancestor in succession of the National Republican, Whig, and present Republican parties. Its origin (see ANTI-FEDERALISTS) was on the question of adopting the Constitution; but it represented two unrelated elements. The commercial interests wished protection at once from foreign aggression, and from barriers set up by independent selfish State legislatures; the patriots pure and simple wished a strong and energetic nation, able to command respect and secure fair treatment. The union of these, their reinforcement for the time by the more statesmanlike even of the Anti-Federalists and Washington's influence, gave them complete control of the new government. They organized the executive departments (see EXECUTIVE) anew, and created the federal judiciary and the Territorial system. The Hamilton, the greatest man of the party and its natural leader, pushed through his schemes for paying the foreign and funding the domestic debt in full, restoring national credit and for assuming the State debts, binding the States to support the new government (see DISTRICT OF COLUMBIA for the "log-roll" which carried it); excise laws, a United States bank, a protective tariff and bounty system to develop manufactures and agriculture, and a postal system, followed rapidly; and in 1794 the crushing of the Whiskey Insurrection (q.v.) showed the new national strength. Meantime the refusal to be dragged into an alliance with revolutionary France had fused the Democrats with the Republicans, the successors of the Anti-Federalists; and Jefferson had organized and Madison joined the new Democratic-Republican party. The most influential Federalist leaders besides Hamilton were Adams and Jay, among others were the "Essex Junto" (q.v.), Fisher Ames, Roger Sherman, Jonathan Trumbull, Rufus King, Gouverneur Morris, Jonathan Dayton, Elias Boudinot, William Bradford, James A. Bayard, John Marshall, Richard Henry Lee, C. C. Pinckney, and William Smith. The party began a new navy, but was prevented by the Democrats from going on with it. This ultimately killed the Federal party; unable to protect commerce by force, it had to do so by humiliating concessions to England, and thus become dependent on and an apologist for that country, which alienated public confidence. By 1796 it had become almost entirely a northern party. The French war afforded a chance of increasing the navy, which they did; but they committed the huge folly of passing the Alien and Sedition laws (q.v.), gratifying resentment at the expense of votes. Finally, when Adams took away their one issue by ending the French war (see ADAMS, JOHN), the Hamilton wing broke with his, and the Democrats ousted the party in the elections of 1800. Its course in opposition deprives it of respect; when the Democrats almost at once dropped their original tenets, practically if not theoretically, and acted on those of the Federalists, the latter (as in the Louisiana Purchase, a pure Federalist measure) changed coats with the Democrats and fought them on their own discarded ground. Their best patriotic elements deserted them in swarms, and in 1804 they carried only Connecticut and Delaware and part of Maryland. But the Embargo (q.v.), and the selfish attempt of the agricultural sections to sacrifice the entire commerce of the country to their own supposed interests, temporarily reinforced the Federalists; in 1808 they had every New England State but Vermont (the only one with no seaboard), besides Delaware and parts of Maryland and North Carolina. The War of 1812 was so unpopular in the North that in the elections of that year New York and New Jersey went Federalist also, and Maryland solid; and the balance of power was held by the three backwoods States of Kentucky, Tennessee, and Ohio, — or by Pennsylvania, whose agricultural west had now swamped the Philadelphia region. But the party as such was really dead; half the old leaders were gone, several of the others had turned Democrat or Independent, Marshall was imbedding its best principles in the national system from the Supreme bench; the chief men now were King and Pinckney. When the war closed, the issue on which the commercial sections had joined them was closed and these at once deserted the party; the Hartford Convention (q.v.) had driven all the remaining leaders out of public life with the stigma of secession and treason; and in 1816 the party carried only Massachusetts, Connecticut, and Delaware, with three Maryland electors who would not vote. The scattered Federalists in Congress did not act as a party, having no issues even as a pretense, and as a national party it ceased to exist. Statewise, it controlled Connecticut and Delaware till after 1820, and Massachusetts till 1823, when the Democrats swept even Essex County from the «Junto.» It lingered for some time also in Maryland and North Carolina.

Federals, the name given to those who during the Civil War in the United States fought to maintain the Union of the Federal States, as opposed to the Confederates.

Federation of Labor. See AMERICAN FEDERATION OF LABOR.

Federmann, Nikolaus, nē'kō-lous fā'dĕr-män, German explorer: b. Ulm, Swabia, 1501; d. about 1542. He was sent to Venezuela by the Welsers of Augsburg, becoming chief lieutenant of Alfinger, and making explorations into the interior of the country. He returned to Europe 1532, going back to Venezuela 1534, as the lieutenant of George of Speyer. He did not follow the latter on one of his expeditions, as ordered, but made an independent exploration with 200 men, spending some years in the valley of the Orinoco, and reaching New Grenada in 1539, where he met Gonzulo Kuesada, already in possession, and relinquished the region to him. Federmann returned again to Augsburg, but was discharged by the Welsers for misfeasance. His account of his first exploration was published in German, 'Indianische Historia,' 1557, and in French 1837.

Fee, John G., American abolitionist: b. Bracken County, Ky., 9 Sept. 1816; d. Berea, Ky., 12 Jan. 1901. He entered the Lane Theological Seminary, Cincinnati, Ohio, in 1842, and soon afterward began to preach against slavery. As a result he was mobbed several times, but in 1853 went to Berea, Ky., where he succeeded in founding a church and establishing Berea College (q.v.), an institution open alike to blacks and whites.

Fee, Fief, or Feudum, is a legal term of feudal origin, signifying an inheritable estate in land, held by some superior, or lord; as distinguished from *allodium*, which is land held by absolute ownership. In the United States, however, where land is generally held in allodium, the private ownership is termed the *fee*, if subject to no paramount right except that of the State. In England the legal theory is that all the lands of the kingdom, except the royal domains, are held in fee, or by a tenure, of some superior lord, the absolute or allodial property being only in the sovereign, so that all the tenures are strictly feudal. This was a significant doctrine while the feudal system flourished in Europe; and the remnants of it are still blended, in a greater or less degree, in the land titles, or rather as a theoretical doctrine, from which certain inferences are drawn, than a plain, direct, practical fact; for the property of a proprietor in land held in *fee simple*, in England, is as absolute, to all intents and purposes, as where the land titles are allodial, there being no practical or theoretical doctrine of a tenure, or holding under a superior. *Fee tail* is any fee granted upon condition; or a fee limited to any particular heir or class of heirs; a qualified fee as differing from fee simple.

Fee Simple, an inherited estate belonging to the owner, his heirs and assigns forever. This is the most complete and exclusive interest that the possessor of lands can have in them, and the word continued to be employed in real estate law after the feudal system had passed away. This is the case even in the United States, where land is generally held in allodium (q.v.) and subject to no paramount claim excepting that of the eminent domain which belongs to the State.

Fee Tail, an estate limited to a certain line of descent, to certain heirs or to a certain class of heirs; sometimes known as a conditional fee.

Feeble-minded, Education of. The term feeble-minded is now used to embrace all classes and grades of the mentally defective, excepting the insane, who, properly speaking, are mentally sick. Idiocy was the term formerly used to cover the same range. Idiocy or feeble-mindedness may be defined as «mental deficiency depending upon imperfect development, or disease of the nervous system, occurring before, at, or after birth, previous to the evolution of the mental faculties.» At the time the feeble-minded were first taught, it was supposed that their growth of body and mind, which was seen to be but partial, had simply been stopped by malign influences, and that in many cases all that was needed was proper environment in order to start the growth again; it was hoped that the improvable cases at least could be educated and trained to approach in capacity the normal-minded individual. The first attempts to train the feeble-minded in this country were made in 1848. Before that time idiots who were not kept at home were to be found in almshouses or in insane asylums. Kind-hearted physicians who saw this «rubbish of humanity» cowering in terror before lunatics or abused by almshouse associates, agitated for their relief, care, and training. The movement began in New York and Massachusetts in the year 1846. In the latter State the legislature appointed a commission to report upon the number, condition, and the best means of relieving the idiots in the commonwealth. Dr. Samuel G. Howe, the director of the Perkins Institution for the blind, was made chairman. The report made in 1848, and widely known as «Dr. Howe's report on idiocy,» was exhaustive, and ended by recommending the opening of an experimental school. One was opened at the expense of the State and under the guidance of Dr. Howe himself. The results were so favorable that in three years' time the State doubled its appropriation, and founded in South Boston the Massachusetts School for Idiots, the first State school for them. The State of New York followed, establishing its school similarly, or experimentally, in 1851, and permanently in 1853. Between the appointment of the Massachusetts commission and its report, a country physician, Dr. H. B. Wilbur, had opened a small private school for idiots at Barre, Mass., really the first school of its kind in America. Dr. Wilbur was soon called to take charge of the New York State school. The Pennsylvania school followed in 1852, and was established in Philadelphia as a private corporation in 1853; then in 1857 came the Ohio State institution at Columbus; in 1858 the semi-public school in Lakeville, Conn.; the Kentucky State school at Frankfort in 1860; the Illinois State school in 1865; the Hillside home, a private school at Fayville, Mass., in 1870. "Thus up to 1874, 26 years after this work was begun in America, public institutions for the feeble-minded had been established in seven States. These institutions then had under training a total of 1,041 pupils. There were also two private institutions in Massachusetts, with a total of 69 inmates." Applications for admittance were numerous and pressing. At first it was the theory that only imbeciles, the improvable idiots, should be taken into the institution, that the institution should be a school and should graduate its pupils into the world. But most of the superintendents soon recognized that the pupils would always be children though adult in years; that they needed guidance and protection always; that for obvious reasons girls and women of child-bearing age should not be discharged — for no girl is so exposed as the simple, weak-willed, feeble-minded girl — and finally that practically all cases would have to be retained within the institution. Physiology and pathology now teach that "mental deficiency generally, if not always, is the result of a definite cerebral abnormality or defect, or the result of actual disease or damage to some part of the central nervous system"; that feeble-mindedness is practically a permanent condition, and that it cannot be cured. From the time this fact came to be realized the institutions began to change in character. There arose two distinct departments — the training school and the asylum.

The school is the fundamentally important department. Education is just as much a right of the improvable imbecile as it is of any child. The aim in the education of an ordinary child is to give a liberal all-round training, fitting him for anything in life he may choose to take up. With our feeble-minded child the aim of his education, which is to lead a useful life within the institution, is kept ever in mind. He is happiest when occupied. Hence his education is principally practical. The difference between a normal person and a feeble-minded person after training is that the latter has no initiative, no power to resist the seduction of stronger minds. He may be useful and even self-supporting, but he can become so only under guidance and direction. When they come to school these children have extremely weak will power. In fact, the feeble-minded as a class have been divided by Sollier according to the attention, thus:

"1. Absolute idiocy. Complete absence and impossibility of attention.

"2. Simple idiocy. Attention feeble and difficult.

"3. Imbecility. Instability of attention."

With all these the condition of the hand indicates that of the brain. The "idiotic hand" is proverbial. Many imbeciles see but do not perceive; hear but do not understand. They rarely make a purposive effort, but need to be directed in everything. When it is comprehended that though they love games they do not even play of their own accord, it will be understood how their teachers must begin at the very bottom rung in the ladder of education. The special senses of seeing, hearing, and feeling, actually have to be aroused and developed, (1) as simple physiological functions; (2) as intellectual faculties. Callisthenics in classes, marching to music, military drill — movements and exercises of all kinds — exert a most salutary and energizing influence, and are in great use in all the schools. The normal child does not need to be taught each step; his power of attention, his will, his desire, his originality enable him to fill the gaps in instruction from his own daily experiences. On the contrary, the feeble-minded child has to be taught each step, hence, his education is extremely slow. The simple occupations of the kindergarten fit these children of 8 to 12 years of age as they do bright children of 4 and 5. The teacher devises all manner of busy work for them, generally using coarse materials; the stringing of spools; beads; buttons; spool-knitting; plain knitting; braiding with broad leather strips, with shoe-strings, with straw; and block building from the simple cube to the forms that are more complex. No instruction is in more general use and is more helpful to the children than that of the kindergarten. After this all their education continues on a very elementary plane beyond which it is impossible for them to go. Many learn reading, writing, and arithmetic. The brightest read simple stories with pleasure, and go as far in arithmetic as multiplication. Division is beyond them. Calculation in the abstract they cannot master. The greater part of their education is, therefore, of a purely practical kind. They are taught a good deal of fancy work, like knitting, crocheting, embroidery, and lace-making; but chiefly domestic work, sewing, washing and ironing, baking, farming, house-painting, shoemaking, brushmaking, etc. Entertainments are very frequent at these institutions, and the "men and women children" are always present. No discrimination as to age or capacity is permitted, and happiness prevails. The institution is a small community. It must have a given number of employees, one or more to each section or department. But the stronger grown up children do the bulk of the work: baking, laundry work, shoemaking, sewing, mending, dressmaking, and tailoring. Each institution aims to have as many acres of land as it has children, and on the grounds a barn, cattle, horses, and all the paraphernalia of a farm. This farm is worked by the boys. By utilizing the energies of the pupils in profitable labor the average per capita expense may be reduced to $125 or $150 a year. Supt. Doren of the Columbus institution has said that if the State will provide him 1,000 acres of good land he will care for all the custodial cases in Ohio free of expense to the State. When an old school has moved to a new site as the Massachusetts school has recently done, the labor of the boys has been utilized in clearing the land and ditching it, in building the roads, etc. Where the grounds contain suitable clay soil, as at Fort Wayne, Ind., the boys have made the bricks with which to build new structures as needed. But in all this care is taken that there is no overwork. The work of an average laboring man more than supports himself — it is generally reckoned to support three people. If the feeble-minded man does one half or one third of a man's work, and does it every day, his support costs only that which will pay for his superintendence and care. The lowest cases of the unimprovable idiots, whom nearly all the institutions have been forced to admit, are termed the "custodial cases," and are kept by themselves. They are profoundly helpless, can neither speak nor attend to their bodily wants, but must be cared for like babies, which they are. Attendants willing to do this work are not easily found. But trained feeble-minded girls are delighted and flattered at the privilege of taking care of those more helpless than themselves. And it has been found that they make the best attendants for such cases. So far, then, as methods of instruction go, American teachers have but broadened the physiological methods of the Frenchman, Seguin. The distinctive results of our schools lie in training the pupils to be helpful, especially in the way of labor for these institutions.

A distinctive result of work for the feeble-minded has been the gathering of statistics of causes. It has been known that a very large percentage of cases, variously estimated from 50 per cent to 70 per cent, are of congenital origin; that of all classes of defectives the feeble-minded most surely tend to transmit their defect; hence, that the feeble-minded must be sequestrated for life. It has been shown that there is a strange but strong correlation between the forms of degeneracy, namely, the criminal, the inebriate, the prostitute, and the feeble-minded. Of late years the energies of charitable and sociologic organizations "have turned toward combating the causes of degeneracy, thereby protecting posterity." The United States census for 1890 gives in round numbers 95,000 feeble-minded, and this number is undoubtedly short of the actual number. Still but one twelfth or about 8,000 of those returned in the census are cared for in special institutions. Here is a terrible problem ahead for the sociologists to work out. Those who have most thoroughly studied the feeble-minded are convinced that, as prevention is cheaper than cure, so the gathering of all this vast army into institutions and especially colonies where 50 per cent of them can be taught to be at least partly self-supporting, and where their multiplication can be cut off, is, by all odds, the most economical and the best policy for the States to pursue in the future. It should not be forgotten that for every idiot cared for we restore at least one productive person to the community. The matter is receiving widespread and intelligent attention. The work for the feeble-minded is considered by those in it as being still in a tentative stage. Nearly all the superintendents are physicians; they do not agree on the different questions involved. They meet regularly in convention, and have an organ of communication, called 'The Journal of Psycho-asthenics.' As the methods of teaching the feeble-minded and the other defective classes have become understood, they have modified the old methods of teaching children of normal intelligence. Child study is now interesting teachers, and already has led to the sending of many feeble-minded children to special schools for their training. The city of Providence, R. I., has recently led the way in a new movement, that of teaching in special classes the dull or backward pupils of the public schools. The movement is slowly spreading elsewhere, and, in justice both to the dull and the bright children, is of inestimable value, and, as such, is a hopeful sign of the times.

Edward Ellis Allen,
Principal of the Pennsylvania Institution for the Instruction of the Blind.

Feed Pump, a force-pump, for supplying the boiler with water.

Feeder, (1) a stream, fountain, or channel which feeds or supplies a main stream or canal with water. (2) A branch or side railway, intended to bring traffic to the main line. (3) In hydraulic engineering, a feeder is a water-course, natural or artificial, carrying water to a canal or reservoir. (4) In mining, the side branch of a vein which passes into a lode. (5) In sewing-machines, that part which carries the cloth along the length of a stitch between each penetration of the needle. (6) In machinery, an auxiliary or supplying part of a machine, that which leads along the stuff being operated on. (7) In iron founding, a head or supply of fluid iron to a runner or mold in heavy castings. (8) In nail-making, a contrivance with an intermittent oscillating or semi-rotary and forward motion to present the plate to the cutters, so that the head of the nail may be taken from the respective edges alternately. (9) In printing, a device with fingers which take the top sheet from a pile and lead it into the press where it is printed or folded. (10) In steam engineering, a device for supplying steam boilers with water in quantities as required. Automatic boiler-feeders act by means of floats on the surface of the water in the boilers. (11) In threshing, the grain-feeder, which forwards the opened sheaves into the throat of the thresher, or the grain into the eye of the millstone, or the grain and chaff from the hopper to the riddle of a winnowing machine, or the grain from the bin to the manger of sheep or other stock. (12) In electricity, a lead in an electric central station distribution system, which lead runs from the station to some point in the district to supply current.

Feeding, Forced, a mode of putting food into the body of persons who are incapable of feeding themselves, or who refuse to take food. In many protracted diseases, such as typhoid and pneumonia; in certain stages of tuberculosis; in cancer of the stomach; in ulcer of the stomach, and in other conditions, it may be impossible for the patient to hold food in the stomach. Under such circumstances feeding by rectum may be practised. (See NUTRIENT ENEMATA.) Forced feeding more properly applies to the giving of nourishment to those who are suffering from one of the insanities, and by reason of their disease refuse food. They may be fed either through the stomach-pump or by means of rectal enemata, the former being the method to be preferred. In this the physician passes a soft rubber tube through the nose into the œsophagus and stomach, care being taken that the tube does not pass into the larynx.

Through the tube, then, either by means of a Davidson syringe or through a funnel, the food, usually milk, is passed. Insane people rarely attempt to vomit their food after it has been once passed in this way, although many refuse to take it and swallow it in the ordinary manner. If forced feeding by way of the rectum is necessary, nutrient enemata (q.v.) may be employed.

Feeding Machine. By this name are commonly known the machines used to automatically supply printing-presses or the like with paper sheets. Printing of a high grade is not done on the great web printing machines, which feed from a roll of paper. Those are built for speed, but for fine printing presses of the single cylinder type, using single sheets of paper are almost universally used. Such presses were always fed by hand until about 1895, when the first practical paper-feeding machines for printing-presses began to come into use. The first of these machines to secure a considerable sale was the Economic feeder, made by E. C. Fuller & Company of New York. In its latest form the Economic feeder is attached at the rear of a cylinder printing machine, and lifts a sheet of paper from the top of a pile by first buckling the two rear corners, then blowing air under the buckled sheet to separate it wholly from the rest of the pile, after which the sheet is advanced or pushed forward to the guides of the press by means of rubbers and traveling endless tapes. The pile of paper from which the sheets are fed is placed on a platform that is arranged with mechanism for raising it very slowly, so that the top of the pile is always kept at substantially the same level. The perfecting of these machines has been obtained only after very costly experimenting, and the addition of improvements as defects were found. Paper piled in sheets has a tendency to stick together, in fact, sheets are sometimes actually glued in spots, as by the crushing of an insect between them. The automatic feeding machine has to provide for such contingencies, and when a torn sheet is found, or a wrinkled one, or two sheets stuck together, the feeder must not only be stopped, but the printing-press also must be brought quickly to a standstill or damage results. Ingenious automatic devices have been introduced for controlling these conditions, and the machines are now commonly used in connection with the printing of magazines of large circulation, some of the larger magazine and book printers employing as many as 30 or more feeding machines in one establishment. The Economic machines will accommodate 10,000 to 20,000 sheets of paper at a single loading, which saves the time formerly lost by the hand feeder about once in 1,000 sheets, in stopping to put up another pile. There is also a saving in soiled sheets, in wages paid, and often in the speed at which the printing-press can be run. The Economic feeder is built in a slightly different form for use with paper-folding machines and with paper-ruling machines. See FOLDING MACHINE.

The Dexter feeding machine was introduced in New York about 1900. Its general characteristics resemble the Economic, but the details of mechanism are different. Dexter was the first to introduce a machine driven by floor connections, which secures greater rigidity than when driven by a chain from the cylinder of the press. Non-electrical devices are employed throughout, some of the most ingenious being the devices for calipering the sheet, to make sure that two sheets do not go into the press together, and the controlling apparatus for tripping the impression of the printing cylinder if a sheet is missed or fails to come down properly to the guides. The Dexter Company also builds folding machines, and their feeders are adapted to use with these, as well as for ruling machines.

The Cross paper-feeder, made by the American Paper Feeder Company of Boston, does not occupy any floor space, as do those previously described, being located above the feed-board of the press. It accommodates several hundred sheets at a time, and reloading is accomplished without stopping the press. It requires no adjustments for quality or weight of paper, and is practical for short as well as long runs. The sheets of the pile are combed out, then turned completely over and reversed in direction, and guided one by one to the feed-guides of the press. The Harris printing-press, a small rotary machine for envelopes, cards, etc., employs a feeding mechanism that should be mentioned in this connection. It automatically picks an envelope or card from the bottom of a pile and carries it into the press. The attendant loads on more cards or envelopes without stopping the machine. See PRINTING; AMERICAN PRINTING TRADE.

Feed-water Heaters, in steam engineering, are devices in which feed-water is heated to a certain extent, before it is introduced into a steam boiler. If cold water is fed into a hot boiler, its chilling action upon the plates and other metal parts causes them to undergo a powerful contraction, which often strains the structure so that leakage occurs about the riveted joints, tube ends, and other places where the parts of the boiler are secured to one another. If the water is heated as nearly as practicable to the temperature prevailing within the boiler, these contraction strains are in large measure avoided, and the life of the boiler is correspondingly prolonged. Furthermore, many feed-waters contain compounds of lime in solution, which are in large measure precipitated by the action of heat. If such a water is fed into the boiler cold, these compounds are thrown down within the boiler, where they form a most troublesome scale, sometimes of stony hardness, upon the heating surfaces. When a heater is used, these objectionable matters are precipitated in the heater itself, which should be so designed that it can be periodically opened and cleaned. (See SCALE.) Another highly important feature of the feed-water heater is that it enables the engineer to utilize a considerable quantity of heat that would otherwise be wasted. When (as is often the case in certain localities) it is impossible to avoid the use of a feed-water highly charged with lime, the primary object in using the heater may be to effect the removal of the lime, as explained above; and in this case the heating is often effected, wholly or in part, by live steam drawn directly from the boiler, because in this way it is possible to attain a higher temperature, and a consequently more perfect precipitation. In other cases, however, it is usual to effect the heating either by means of exhaust steam, or by the hot gaseous products of combustion as they pass from the boiler to the chimney or stack. When the hot flue gases are utilized for this purpose, the heater is commonly called an «economizer,» and usually consists of a series of tubes through which the water to be heated circulates, these being placed in a chamber which the flue gases are obliged to traverse on their way to the chimney. Flue-heaters, or «economizers,» are very common in England, but they are not generally met with in the United States, although their use in this country is increasing. The exhaust-steam heaters are divided into two general classes, known respectively as «closed heaters» and «open heaters.» In the closed heater the exhaust steam from the engine is caused to flow through a series of tubes which are surrounded by the water to be heated, the steam giving up its heat to the water through the walls of the tubes in such a manner that the vapor and liquid never come into contact with each other. In open heaters, on the other hand, the steam and the water to be heated are brought into intimate contact with each other in a chamber or tank, into which the water is introduced in the form of thin sheets or spray. High feed-water temperatures are attained more readily in open heaters than in closed ones, and for this reason the open form is much used when the removal of scale-forming matter from the water is the chief object in view. On the other hand, exhaust steam is apt to carry over considerable quantities of oil from the engine, and when an open heater is used this oil mingles with the feed-water and so is introduced into the boiler, where it is likely to give trouble by adhering to the heating surfaces and causing them to become overheated and burned or bulged.

Fee'han, Patrick Augustine, American Roman Catholic prelate: b. Tipperary, Ireland, 29 Aug. 1829; d. Chicago, Ill., 12 July 1902. He was graduated from Maynooth College, Ireland, came to the United States in 1852, when he was ordained; and soon after became president of the Seminary of Carondelet. He had charge of St. John's Church, St. Michael's, and the Church of the Immaculate Conception, all in St. Louis, till 1865, when he became bishop of Nashville; and was installed as first archbishop of Chicago in 1880. During his administration as archbishop he founded several new parishes, a college of the Christian Brothers and other institutions.

Feejee Islands. See Fiji Islands.

Feeling, the sense of touch, emotion. See Emotion; Psychology.

Feer-Herzog, Karl, kärl fãr-hĕr'tsoh, Swiss statesman: b. Rixheim, Alsace, 2 Oct. 1820; d. Aarau 16 Jan. 1880. He became a member of the Grand Council 1852 and was twice its president. In 1865 he was made Swiss representative in the Latin Monetary Union, which position he held for the rest of his life. He was director of the Swiss department of the Paris Exposition 1867, and for many years was president of the Swiss Financial Commission. Among his works are: ‹Unification monétaire international› (1869); ‹La France et ses allies monétaires› (1870); ‹Gold oder Silber?› the latter in German (1874).

Feet Washing, or Washing of Feet, a religious ceremony observed in the Roman Catholic Church, on Holy Thursday or the Thursday before Good Friday. This ceremony takes place just after everything has been removed from the altar. The pastor or principal prelate of the church washes the feet of 12 men, in imitation of the action of Jesus Christ, when he washed the feet of the apostles. The Pope washes the feet of 13 priests. The ceremony is sometimes called «Mandatum» from the first word of the antiphon sung during the ceremony: «Mandatum novum,» etc.: «A new commandment I give unto you that you love one another.» This custom, although mentioned in the Council of Toledo (694), is not now generally recognized.

Fehling, Hermann, hĕr'män fā'ling, German chemist: b. Lübeck, Germany, 9 June 1811; d. 2 July 1885. He studied chemistry in Heidelberg, at Giessen in Liebig's laboratory and at Paris. He became professor of chemistry in the Polytechnic School at Stuttgart, and professor emeritus in 1882. He had great authority in the educational and manufacturing circles of his time, as a teacher and prescriber of chemical formulæ for commercial products, such as sugar, and mineral waters. The so-called Fehling's' Solution (q.v.) is famous. He wrote: ‹Text-book of Organic Chemistry›; translated Payen's ‹Précis de Chimie Industrielle,› and edited a new edition of ‹Glossary of Chemical Terms.›

Fehling's Solution, a solution much used by chemists for the detection and estimation of glucose and certain other sugars. In its preparation, 34.64 grams of pure sulphate of copper crystals are dissolved in 200 grams of distilled water, and (separately) 173 grams of crystallized neutral tartrate of sodium are also dissolved in 500 or 600 grams of a solution of caustic soda having a specific gravity of 1.12. The copper solution is then gradually added to the caustic soda solution, and the mixed liquid is diluted to one litre. Fehling's solution must be freshly prepared, for, like all other copper test solutions, it becomes unreliable in a short time, thereafter indicating sugar where none exists. For use, a small quantity of the solution is placed in a test tube and diluted with about four times its bulk of water. It is then boiled for a few seconds, and if it remains clear, it may be considered to be in good condition. The fluid to be tested is then immediately added, drop by drop, until a bulk equal to that of the diluted test fluid has been added. If glucose is present a yellow precipitate of hydrated cuprous oxid is thrown down, which subsequently loses its water of hydration and becomes reduced to ordinary red cuprous oxid. When prepared as described above, one cubic centimetre of the standard (undiluted) solution corresponds to five milligrams of glucose. Fehling's solution is of a deep blue color, and in testing a complicated organic fluid (such as urine) for glucose it often happens that the test solution is decolorized even when no glucose is present. It is, therefore, important to observe whether or not an actual precipitate is formed, as mere decolorization is not a sufficient indication. Cane-sugar does not reduce Fehling's solution in the cold, but it does so when warmed, because heat changes cane-sugar to a mixture of glucose and fructose in the presence of the alkali that the test solution contains. See PAVY'S SOLUTION; URINARY ANALYSIS.

Fehmarn. See FEMERN.

Fehmgerichte. See VEHMGERICHTE.

Feia (fā'ya) **Lake,** in the province of Rio de Janeiro, in Brazil, near the coast. Area, 192 square miles. Connections by canals have been made with the Parahyba River on the north and the Atlantic on the east.

Feigned Disease. See HYSTERIA.

Feijo, or **Feijoo, Diogo Antonio,** dē-o'go än-to'nē-ō fā zho', Brazilian statesman: b. São Paulo, Brazil, 1784; d. 1843. As a priest he did pastoral work for many years, and in 1822 was elected to the Cortes, Lisbon, Portugal. When Brazilian independence was won he returned to America; in 1826 was chosen by the Liberal party as their deputy and representative, and introduced measures for municipal reform and the abolition of clerical celibacy. He served as minister of justice 1831–2, but in 1837 he retired from politics, before the storm of Conservative opposition which his liberal policy had called up.

Feisi, Abul Feis ibn Mubárak, ä'bool fā ēs ibn moo-bä'räk fī'si or fā-ē-sē', Indo-Persian poet and scholar: b. Agra, India, 1547; d. there 1595. He surpassed all his contemporaries in philological, philosophical, historical, and medical knowledge, and about 1572 was crowned «king of poesy» in the court of the Emperor Akbar. Of his poems the most noteworthy are his lyrics — odes, encomia, elegies, and specially his four-line pieces or apothegms. Their exalted pantheism brought on him the enmity of the orthodox Moslem clergy. He wrote also many double-rhymed poems; and a Persian imitation of the famous Indian epic: 'Nala and Damajanti,' designed to form the third member of an epic cycle of which the first was to be 'The Centre of the Circle,' the second 'Solomon and Balkis' (the Queen of Sheba), the fourth 'The Seven Zones of the Earth,' and the fifth 'The History of Akbar'; only the first and third were completed. His scientific treatises were numerous.

Feith, fīt, **Rhijnvis,** Dutch poet: b. Zwoll, Over-Yssel, 7 Feb. 1753; d. there 8 Feb. 1824. He was made burgomaster, and afterward receiver at the admiralty college in Zwoll, but did not cease to cultivate the art of poetry, and to enrich Dutch literature. He tried his powers in almost every department of poetry. In his earlier years he was too much inclined to the pensive and sentimental style. It predominates particularly in his romance 'Ferdinand and Constantia' (1785), and, through his example, has for a long time prevailed in Holland. His 'Grave' (Het Graf, 1792) is the first distinguished didactic poem since the revival of Dutch poetry. His 'Old Age' (De Ouderdom) appeared 1802. Among his lyric poems, 'Oden en Gedichten' (1798), are several hymns and odes distinguished for great elevation and feeling. His ode on 'Ruyter' is very celebrated. He also made that naval hero the subject of an epic poem. The best of his tragedies are: 'Thirza'; 'Johanna Gray'; and particularly 'Inès de Castro.' His poetical 'Letters to Sophia on Kant's Philosophy' (Brieven aan Sophie over de Kantiaansche Wijsbegeerte, Amsterdam, 1805) are a feeble effort of his old age. Among his prose works, his 'Letters on Different Subjects of Literature' (1784), contributed much to the dissemination of good taste, by their finished style and excellent criticisms.

Felch, Alpheus, American lawyer and politician: b. Limerick, York County, Maine, 28 Sept. 1806; d. 1896. He was graduated at Bowdoin College 1827, was admitted to the bar and practised law in Michigan, being elected to the legislature of that State 1836, and appointed bank commissioner 1838–9. He was judge of the Supreme Court 1842–45; governor of Michigan 1846–7; and United States senator 1847–53; he was appointed professor of law in Michigan University in 1879, holding that position till 1883.

Feldmann, Leopold, lā'ō-pōlt feld'män, German dramatist: b. Munich, Bavaria, 22 May 1802; d. Vienna 26 March 1882. In 1835 appeared his 'Lays of Hell'; next the comedy 'The Son on His Travels,' which made a brilliant success at Munich. After five years in travel, chiefly in Greece, as correspondent of the 'Allgemeine Zeitung,' in 1850 he settled in Vienna for life. His comedies were very popular in their day. Among them are: 'Free Choice'; 'Sweetheart's Portrait'; 'The Late Countess'; 'The Comptroller and His Daughter.'

Feldspars, the most important group of silicate minerals. They are characterized by monoclinic or closely related triclinic crystallization, the frequent occurrence of twin crystals, cleavage in two similar directions inclined at an angle of 90° or nearly 90°, a hardness of about 6, a specific gravity between 2.5 and 2.9, a light color, usually white, pale yellow or green, or flesh-red, a white streak and a low relief and low order of interference colors as seen in thin sections with the polarizing microscope. In composition the feldspars are all silicates of aluminum, combined in the different species with one or more of the common alkaline bases, potash, soda, or lime, or rarely baryta. Magnesium and iron are conspicuously absent.

Forms.— Feldspars occur in massive, granular, lamellar, cleavable, and compact forms, but crystals are very common. The monoclinic feldspars include orthoclase, or common feldspar, and the very rare barium feldspar, hyalophane. Triclinic feldspars include microcline, anorthoclase, and plagioclase or the feldspars of the albite-anorthite series, embracing albite, oligoclase, andesine, labradorite, and anorthite. Descriptions of these minerals appear as separate topics. The feldspar group presents a striking illustration of the approximation in angle to forms of higher symmetry coincident with a wide difference in habit. In orthoclase, for example, the common planes *n, y* approximate very closely to the cube; *q*, to the octahedron; *m, b, c, o* to the dodecahedron, and *z, x* to the trapezohedron. Feldspar crystals usually appear prismatic and are often tabular parallel to the clinopinacoid, *b*. Twins of most remarkable variety abound, the commonest of which are after the Carlsbad, Baveno, albite, and pericline laws (see CRYSTALLOGRAPHY). Polysynthetic twinning is almost universal in the plagioclase feldspars, and, while best observed in thin sections with the polarizing microscope, it is often detected in large masses by the fine striations which so beautifully mark some of the cleavage faces of labradorite, oligoclase, or albite.

COMPOSITION AND PHYSICAL PROPERTIES OF FELDSPARS.

Mineral.	Formula.	SiO_2	Al_2O_3	CaO	Na_2O	K_2O	Hardness	Fusibility	Cleavage	Specific Gravity	Extinction on *c*	Extinction on *b*
Orthoclase	$KAlSi_3O_8$	64.7	18.4	......	......	16.9	6.-6.5	5.0	89°53′	2.57	0°	—3° to 7°
Microcline	$KAlSi_3O_8$	64.7	18.4	......	......	16.9	6.-6.5	5.0	89°30′	2.57	+15°30′	+5° to 6°
Albite ...	Ab = $NaAlSi_3O_8$	68.7	19.5	......	11.8	......	6 -6.5	4.0	86°24′	2.62	+ 3°	+17°
Oligoclase	$Ab_3\ An_1$	62.0	24.0	5.3	8.7	......	6.-7.	3.5	86°8′	2.66	+ 1°	+4°
Andesine .	$Ab_1\ An_1$	55.6	28.3	10.4	5.7	......	5.-6.	3.5	86°14′	2.69	—5°	—17° to 21°
Labradorite	$Ab_1\ An_3$	49.3	32.6	15.3	2.8	......	5.-6.	3.0	86°4′	2.73	—14° to 25°	—28° to 32°
Anorthite	An = $CaAl_2Si_2O_8$	43.2	36.7	20.1	......	......	6.-6.5	5.0	85°50′	2.76	—36° to 42°	—37° to 43°

Optical Characters.— Orthoclase is optically negative, with the axial plane usually at right angles to the clinopinacoid, *b*; but sometimes it is parallel to *b* and always becomes so when the temperature is increased to 600° to 1,000° C., this change also being produced by pressure. Microcline is also optically negative and the axial plane is nearly perpendicular to the *b*-pinacoid. Among the plagioclase feldspars the position of the axial plane changes with the composition, there being a regular progression in its position in passing from albite to anorthite. Albite is optically positive, anorthite is negative, while in some andesine, lying midway between them, the axial angle is practically 90°. Microcline is distinguished from all the other feldspars by the characteristic "gridiron" structure which is exhibited by thin basal sections when viewed under the microscope in polarized light. This is due to polysynthetic twinning according to the albite and pericline laws. The plagioclase feldspars may usually be recognized in thin sections, between crossed nicols, by their characteristic polysynthetic twinning, which manifests itself by parallel bands alternately dark and light.

Composition.—Orthoclase, or potash feldspar, is a potassium-aluminum polysilicate, $K\ Al\ Si_3O_8$. This compound is dimorphous, microcline, having an identical composition. Sodium often in part replaces the potassium, making soda-orthoclase or soda-microcline. When the sodium largely predominates the mineral passes into anorthoclase $(Na,K)Al\ Si_3O_8$; when it excludes the potassium, the mineral is albite, $Na\ Al\ Si_3O_8$. Anorthite is a calcium-aluminum polysilicate, $Ca\ Al_2Si_2O_8$. Between it and albite lie various triclinic feldspars, which are regarded as isomorphous mixtures of albite and anorthite. In the table above, the symbol *Ab* is assigned to albite and *An* to anorthite, and the ratio of these albite and anorthite molecules present in these feldspars is thus shown. The variation of the proportions of the constituent molecules gives rise to innumerable varieties filling up the gaps between the typical species which thus graduate from one into another. The change in chemical composition is attended by a change in specific gravity, fusibility, crystal form, cleavage angle, and optical properties. The foregoing table shows the progressive changes, there being an increase in specific gravity from albite at one end to anorthite at the other, while the fusibility and hardness decrease toward the centre of the series and increase at each end.

Occurrence.— The feldspars are not only the most abundant of all rock-forming minerals, but also the most important from a scientific standpoint, since the present scheme of classification of igneous rocks is chiefly based on the identity of the contained feldspar (see ROCKS). Orthoclase is an essential constituent of granite, syenite, and porphyry, while it is also one of the constituents of gneiss and the other granitoid rocks. Its variety sanidine is the feldspar of trachyte and phonolite. Microcline occurs similarly and is not easily distinguished from orthoclase except by an optical examination, though its two prominent varieties, amazonstone and chesterlite, are quite distinct. Albite is an essential constituent of diorite and is one of the component minerals of many crystalline rocks, occurring associated with orthoclase and microcline in much granite and gneiss. Albitic granite is often the matrix of the rarer minerals, and especially of some of the gems. Oligoclase abounds in granite, syenite, gneiss, diorite, trachyte, andesite, and diabase, often being associated with orthoclase. Labradorite is an essential constituent of various basic, eruptive rocks, in which it is commonly associated with some member of the pyroxene or amphibole groups, as in norite, gabbro, diabase, and basalt. Anorthite occurs in gabbro, basalt, and porphyry.

Alteration.— The feldspars are often altered into other silicates such as talc, chlorite, or the zeolites, but much the most common change is the production of kaolin (see CLAY). Infiltrating waters containing carbon dioxide dissolve out the alkaline ingredients of the spar, which, entering into new combinations, form various secondary minerals, while the aluminum silicate becomes hydrated and forms kaolin. If the waters contain magnesium salts the feldspar may be altered to talc.

Uses.— Feldspar is extensively used in the manufacture of porcelain, serving as a flux to bind together the other constituents, clay and flint. It is also one of the principal ingredients in the glaze for chinaware and tiles, and it has less important applications in soap-making, polishing materials, and dentistry. The beautiful change of colors in labradorite has led to its use for table tops and inlaid work. The gem moonstone is a variety of feldspar, usually oligoclase.

Production.— The production of feldspar in the United States during 1902 amounted to 21,870 short tons of crude spar, valued at $55,501, and 23,417 tons of ground spar, valued at $194,-923. The chief supply comes from Pennsylvania, Connecticut, New York, and Maine. Potash feldspar, that is, orthoclase or microcline, is the material most used. Although it is such an abundant rock constituent, it is comparatively rarely segregated sufficiently to be available for commercial uses. The quarries of greatest value are usually those in which the feldspar occurs in pegmatite dikes, in gneiss or mica schist. The larger masses of mica and quartz are broken and picked out by hand, but considerable percentages of quartz often remain, which, however, within reasonable limits, are not objectionable for pottery, since flint is always mixed with the spar in the process of manufacture. The quarries are nearly all worked by open pits, some of which are of mammoth size, one in Glastonbury, Conn., having produced 200,000 tons, another at Elam, Pa., 100,000 tons.

George Letchworth English,
Mineralogist, New York City.

Félegyháza, fā'ledy-hä-zo, or **Kiskun-Fé,** kish'koon'fĕ, Hungary, town about 65 miles southeast of Budapest. Agriculture and grazing are the principal occupations of the people of the surrounding country and the trade is in cattle, dairy, and agricultural products. Pop. 33,300.

Felicudi, fā-lē-coo'dē (ancient Phœnicusa), one of the Lipari Isles, off the north coast of Sicily, 10 miles west of Salina. It is about nine miles in circumference, has rugged cliffs of basalt, and three lofty summits, evidently produced by an extinct volcano. The soil is both fertile and well cultivated. Pop. 800.

Felidæ, fē'lĭ-dē, the cat family, which contains the most highly developed of the order *Carnivora.* The characters of the family are: the possession of a slender, extremely flexible body, of great muscular power; the limbs five-toed, the thumb of the anterior limbs not reaching the ground; the skull relatively short, the facial portion much shortened, very broad, and giving, by its capacious zygomatic arches, a rounded outline, and abundant space for the powerful muscles which move the lower jaw. The incisors are three in number on each side, above and below; the powerful canines are trenchant on both edges, and are sometimes grooved; the premolars are three above and two below, the molars one above and below — in all, 30 teeth. The premolars are laterally compressed, the third upper tooth, the carnassial, or sectorial premolar, having only a minute inner tubercle. All are digitigrade. The divisions, as given by Carus, are: Sub-genus 1. *Felis.* Claws retractile; limbs low; tail as long as the body. A. Old World forms. (a) Lions (*F. leo*). Color uniform; a mane. Africa and Western Asia. (b) Tigers (*F. tigris*). No mane; body striped. Whole of Asia, from the Altai and Amur to Java and the Caucasus. (c) Leopards (*F. pardus*). Large species, with spots or rings, and round pupils. Africa and South Asia. (d) Serval (*F. serval*). Small spotted species. South Africa. (e) Cats (*F. catus*). Small, not spotted, sometimes striped; pupils elliptic vertical. B. New World forms. (a) Leonine. Color uniform, no mane. Puma (*F. concolor*). (b) Leopard-like. Jaguar (*F. onca*). Sub-genus 2. *Cynailurus.* Claws not quite retractile. Hair on neck and between shoulders, long, manelike. Cheetah (*F. jubata*). Africa and South Asia. Sub-genus 3. *Lynx.* With ear-tufts and short tails. A. Old World forms. Caracal (*F. caracal*) and chaus. South Asia and Africa. B. New World forms. Canadian lynx (*F. canadensis*). Red cat (*F. fasciata*). Bay lynx (*F. rufus*) — all in North America. The family was represented in Tertiary times by the cave-tiger (*F. spelea*); an American species (*F. protopanther*); and an Indian (*F. cristata*). *Machairodus,* with its enormous sabre-like upper canine, ranged from Miocene to Pleistocene times in Europe.

In addition to this formidable apparatus of cutting-teeth, the tongue is covered with small recurved prickles by which they can clean from the bones of their prey every particle of flesh.

There are no quadrupeds in which the muscles of the jaws and limbs are more fully developed. The skeleton presents a light but well-built mechanism; the bones, though slender, are extremely compact; the trunk, having to contain the simple digestive apparatus requisite for the assimilation of highly organized animal food, is comparatively slender, and flattened at the sides. The muscular forces are thus enabled to carry the light body along by extensive bounds, and thus it is that the larger felines generally make their attack. The five toes of the fore-feet and the four toes of the hind-feet of cats are armed with very strong, hooked, sharp claws, which are preserved from being blunted by a peculiar arrangement of the phalanges. For this purpose the claw-joint of each toe is drawn back by ligaments attached to the penultimate joint, till it assumes habitually a perpendicular position, when the claw which it supports is completely retracted within a sort of sheath, and is entirely concealed by the fur. When, however, the animal springs on its prey, the tendons of the flexor muscles of the toes, overcoming the elasticity of the retractile ligaments, pull forward the claws, and they are ready to be buried in the flesh of the victim. The lower surface of the foot is furnished with thick ball-like pads of the epidermis, on which the animal walks; this gives them the noiseless tread peculiar to this family.

Members of the cat family hunt in the gloom, and, consequently, while escaping observation, require every ray of light that can be made available. The pupil is a long, vertical fissure; but this only obtains among the smaller genera; in all of the family above the ocelot in size, the pupil is round in form. On the top of the skull there runs a tolerably high bony crest, which reaches its greatest elevation at the very back of the head. This bone ridge is necessary for the attachment of the powerful muscles which operate the jaws and enable the cats to drag away their often very heavy prey.

In the digestive organs of the *Felidæ,* the salivary glands are small, and the stomach of a simple cylindrical form. The œsophagus opens at its anterior extremity, and the intestine commences from the posterior; so that everything favors a quick passage of the food, which receives no mastication, and is retained a very short time in the stomach. The intestine has no valves, is small in diameter, but muscular, and the whole canal, when compared with the length of the body, is extremely short, being as

3 or 5 to 1. In the domestic cat they are 5 to 1; but in the wild cat only as 3 to 1.

The *Felidæ* are now regarded as including only two genera, *Felis* and *Cynælurus*, the latter reserved for only one species, the chetah (q.v.).

Wild cats are found in all parts of the world except Australia, but principally in the warmer regions, where alone the larger species are met with.

In the caverns and river deposits of the Quaternary Period in Europe and America are found fossil remains of cats allied to or identical with living species. Such are the huge cave lion of Europe (*Felis leo*, race *Spelæa*) and others not so well known. During the Tertiary Period they were rare, their place being taken by the Machærodonts or sabre-tooth tigers (q.v.), animals similar to cats in many respects, but less agile, more powerful, and distinguished by enlarged sabre-like upper canine teeth, which indicate different habits of attack on their prey. The appearance of true cats, both in Europe and America, is correlated with the abundance of modern types of ruminants, etc.— slender, thin-skinned, long-necked, and swift-footed, in place of the powerful and heavily proportioned pachyderms common through most of the Tertiary Period. It is probable that both sabre-tooth tigers and true cats were evolved from the *Palæonictidæ*, a group of primitive carnivora or Creodonta (q.v.), in the early Eocene; but the proof from fossils is at present fragmentary and incomplete.

See CAT; COUGAR; LEOPARD; LYNX, and other names of wild cats.

Felix I., Saint, a citizen of Rome, reigned as pope from 269–74. He excommunicated Paul of Samosta, bishop of Antioch, for teaching that Christ was no more than a mere man. A portion of a treatise on the Incarnation, written by Felix I., is still extant. He was martyred (274) in the Aurelian persecution.

Felix II., Pope. He occupied the pontifical see during the banishment of Liberius, 355. In reply to a proposition for the recall of Liberius, it was proposed by the Emperor Constantius that Liberius and Felix should reign conjointly, but the people exclaimed: "One God, one Christ, one Pope." Felix retired until after the death of Liberius (358) when he was recalled and became pope until he was martyred in the last of the 4th century. By many historians he is called an antipope.

Felix III., Pope, succeeded Simplicius in 483, and died in 492. Under him began the Acacian schism, headed by Acacius, Patriarch of Constantinople. Acacius was excommunicated by Felix III. at the Roman Synod of 484.

Felix IV., Pope from 526 to 530. He is noted for his promulgation of the 25 canons adopted by the Council of Orange (529) against Semi-Pelagians.

Felix V., an antipope: b. Savoy; d. Ripaille 1451. He is better known by his rightful name and titles, Amadeus, Duke of Savoy, Count of Geneva, and Cardinal. He was elected pope by the schismatical Council of Basel (1439), and in 1449 submitted to Nicholas V. who had been elected pope canonically. Felix V. is the last one of the antipopes.

Felix, Antonius, an-tō'nĭ-us fē'liks, Roman procurator of Judea. It was before him that Paul "reasoned of righteousness, temperance, and judgment to come." Felix rose from slavery, having been manumitted by Claudius Cæsar. His rule in Judea, notwithstanding its severity or rather in consequence of it, was marked by constant disorders and disaffection; and but for the interest of his brother (the notorious freedman Pallas) with Nero, the charges carried up against him to Rome would have been his ruin. Drusilla, "the Jewess," his second wife, had been seduced by him from her husband, Azizus, king of Emesa. Tacitus paints Felix in the darkest colors — a character confirmed by what is related of him in the New Testament, that he had expected a bribe from Paul, and that, disappointed in this, he left him bound, "to show the Jews a pleasure." Acts xxiii., xxiv.

Felix, Eugen, oi-gān' fā'līks, Austrian painter: b. Vienna 27 April 1836. He studied art under Waldmuller in Vienna and under Cogniet in Paris, and settled in Vienna 1868. He painted religious and mythological subjects, studies of horses, portraits and interior scenes, among his canvases being: 'The First Friend'; 'Pan and the Bacchantes,' his portraits including those of Rubinstein, and Philip, Duke of Würtemberg.

Felix, Marcus Minucius, mar'cus min nu'shĭ-us fē'liks, Roman lawyer: flourished about 230 A.D. He embraced Christianity, and wrote an excellent defense of it in a dialogue entitled 'Octavius.' The period when he flourished is uncertain, some making it as early as the reign of Marcus Aurelius, while others make it as late as that of Diocletian. The purity of the Latin style, and some of the allusions to the existing state of the Church, would seem to favor the earlier date; but it is not easy to set aside the direct testimony of Jerome, who, in a regular list of Christian writers, places him between Tertullian and Cyprian, thus fixing the period to about 230 A.D. The 'Octavius' has been translated into most European languages.

Felix Holt, the Radical, a novel by George Eliot (1866). It is a picture of upper middle-class and industrial English life of the period of the Reform Bill agitation.

Felix'ians, a Spanish sect of the later part of the 8th century, so called from Felix, bishop of Urgel.

Fell, John, English prelate: b. Longworth, Berkshire, 23 June 1625; d. 10 July 1686. He was graduated at Christ Church, Oxford, 1643, took up arms for the royal cause, and later, at the Restoration, became canon of Christ Church and dean 1660, becoming vice-chancellor of Oxford 1666, which office he held till 1669. He displayed much interest in the development of the University Press, and in 1675 he was appointed bishop of Oxford. Among his works are: 'The Interest of England Stated' (1659); 'The Life of Dr. Henry Hammond' (1661); 'Grammatica Rationis sive Institutiones Logicæ' (1673); 'The Vanity of Scoffing' (1674); and several editions of classical Latin and Greek authors. He was satirized in Tom Brown's famous epigram beginning "I do not like you, Doctor Fell."

Fell (Norw. *fjeld*, Swed. *fjäll*), the name given in Scandinavia to the bare plateaus which occur in its mountainous regions; they are destitute of vegetation, and generally lie above the snow-line. The word enters as a component into the names of innumerable mountains, owing to the fact that in their formation they have taken on the shape of a fell. Fell is also used in the north of England and south of Scotland to designate a barren hill, and indicates Scandinavian settlements. See MIDDLESEX FELLS.

Fellahs, fel'az, or **Fellahin,** fel'a-hēn, the people of Egypt who live in villages and cultivate the soil. The name signifies "tillers." They form a large part of the population; are the most ancient race in that country, and are generally believed to be the descendants of the old Egyptians, their physiognomy resembling that which is found on the ancient sculptures. They are a patient and laborious population, and were heavily taxed before the period of English influence in the government. See EGYPT.

Fellatahs, fel-lä'täz, or **Fulahs,** foo'läz, native **Fulbe,** fool'bĕ, a remarkable race of the negro type, the original locality of which is unknown, but which is now widely diffused throughout the Sudan, where they form a kind of ruling aristocracy. The states or kingdoms of Senegal-Futa, Futa-Jallon, Haussa, Sokoto, etc., are in their hands, and they thus extend from Senegambia eastward to Lake Tchad. Though of the negro family, they differ widely in their physical characteristics from that race. In person they are decidedly handsome, and mostly of a light copper color. They have regular features, small mouths, and noses inclining to aquiline; silky hair, and fine black eyes; and are tall, well proportioned, and of erect and graceful figure. Some of the young women are very good-looking, and would be considered beautiful even in Europe. The Fellatahs are shrewd and intelligent; extremely active, polished, and insinuating in their manners, and said to possess great bravery and perseverance. They are not very much inclined to trade or agriculture, leaving these chiefly to the subject peoples. They are mostly Mohammedans, to which religion they became converts about 400 years ago. In the beginning of the 19th century they spread Islamism through the Sudan and established their dominion over a wide territory.

Fellenberg, Philipp Emanuel von, fē'lēp ā-mä'noo-el fon fel'len bĕrH, Swiss educational and agricultural reformer: b. Berne 27 June 1771; d. Hofwyl 21 Nov. 1844. The years 1795–8 he spent in traveling over France and Germany, visiting in preference the villages, and chiefly devoting his attention to the material, intellectual, and moral condition of the agricultural classes. He became convinced that the cause of all the existing poverty and misery was the absence of sound and rational instruction, and that the remedy lay in combining with a sound general education special training for the pupil's future trade. On his return to Berne he devoted himself to the improvement of the social and intellectual welfare of the peasantry. For this purpose he purchased the estate of Hofwyl, and established successively an institution for instructing the children of the poorer classes, a seminary for children in the higher grades of life, and a normal school. The pupils were all trained to work in the fields or at the bench, and the product of their labor was sufficient to cover the expenses of their education. Fellenberg's scheme was at first ridiculed by his countrymen, and looked upon for a time with some suspicion by the government; but ere long its beneficial results attracted even the attention of foreign governments. Alexander I. of Russia conferred upon the philanthropist the decoration of St. Vladimir, and sent seven young nobles to be educated at his institution. Several foreign princes visited the establishment, and founded institutions on a similar plan. The Fellenberg institutions still exist, though on a less extensive scale, and are partly carried on by his descendants.

Fell'ing, England, town, in Durham County, on the Tyne, two miles southeast of Newcastle. It has chemical works, forges, factories, and coal mines nearby. Pop. 22,460.

Fellows, SIR **Charles,** English traveler and antiquarian: b. Nottingham Aug. 1799; d. there 8 Nov. 1860. Without any claims to classical attainments, he collected unassisted a vast amount of material for the learned to labor upon. He first explored the valley of the Xanthus in Lycia, in 1838, and discovered the remains of the two cities Xanthus, the Lycian capital, and Teos. Under the auspices of the trustees of the British Museum he made further explorations in 1839 and 1841, and succeeded in obtaining the marbles now in the Lycian salon of the Museum. He was knighted by the queen in 1845. His principal works are: 'The Xanthian'; 'Travels and Researches in Asia Minor'; and 'Coins of Ancient Lycia before the Reign of Alexander.'

Fellows, John, American author: b. Sheffield, Mass., 1760; d. New York 3 Jan. 1844. His publications include: 'The Veil Removed' (1843); 'Exposition of the Mysteries or Religious Dogmas and Customs of the Ancient Egyptians, Pythagoreans, and Druids'; 'Mysteries of Free-Masonry'; and a work on the authorship of the Junius letters.

Fellowship, an institution or feature of ancient origin in certain European universities, but of recent introduction in the colleges and universities of the United States. In an English university the fellowship entitles the holder, a graduate, who generally is called a fellow, to participate in the revenues of a certain college, or to have the benefit of a special endowment, and also confers a right to rooms in the college, and certain other privileges, as to meals, etc. Fellowships are generally forfeited upon the attainment of a certain position in the church or at the bar, and are retained after marriage only by special vote of the college. With these exceptions, the tenure was formerly for life, but many fellowships have altered in this respect. In Cambridge the tenure is now limited to six years. Both resident and traveling fellowships are granted for work in a special line. Formerly the value of some of the fellowships at Oxford and Cambridge was equivalent to $2,500, and even $4,000, but great changes have been made in the number and emoluments of the fellows at both universities. At Cambridge there are in all about 400 fellowships, some of the colleges having as many as 50 or 60 attached to them. The average annual value is from $750 to $1,250. At Oxford there are now two classes of fellowships, ordinary and tutorial. The emoluments of an ordinary fellowship are $1,000 a year, those of a tutorial fellowship usually $1,500. New fellows are generally elected by the head of the college to which they belong and the fellows. There are also fellows connected with Dublin University, and in recent years a few have been attached to the Scotch universities. In American universities many fellowships have been established by private individuals, to promote research in special departments of knowledge. Fellowships are frequently awarded for study abroad, but others are for resident holders who, in some cases, give part of their time to instruction. Fellowships, unlike scholarships, are awarded to graduates only. The Johns Hopkins University first used the system extensively. The value of fellowships varies greatly. The most common amount is about $500 per annum, but in some cases the income is only $120 and in others it reaches $1,000. Chicago University has nearly 80 fellowships and several other institutions from 22 to 55 each. Annual fellowships may generally be reassigned more than once to the same holder, and there are fellowships with a tenure of several years. There are several fellowships at the American schools of classical studies in Athens and in Rome, open to graduates of American universities.

Felltham, or **Feltham,** fĕl'tham, **Owen,** English author: b. Mutford, Suffolk, probably 1602; d. Great Billing, Northamptonshire, 1668. He resided in the family of the Earl of Thomond, had strong royalist sympathies, was well known to the literary men of his time, and published a work of great merit, entitled: 'Resolves, Divine, Political, and Moral.' This book went through 12 editions by the year 1709.

Felo de se, fē'lo dē sē, from the mediæval Latin, felon or traitor to himself, is the legal technical description for a suicide. See Suicide.

Felony, in law, a term originally applied to those crimes which were punished by forfeiture of lands and goods, in addition to any other punishment prescribed by law. As so used it was distinguished from a *misdemeanor,* which was an offense that did not entail forfeiture as part of the penalty. The word cannot now be said to have any very definite meaning in law. It may be applied to crimes entailing capital punishment, as well as to others for which capital punishment is not inflicted; and is so applied by statute in the States of New York and Massachusetts. In many States the distinction between felony and misdemeanor has been abolished, an example that in time will probably be universally followed. Compounding a felony in refraining from prosecuting a felony for a consideration, constitutes a crime.

Fel'site. As a rock name, felsite is rather indefinite but is a very convenient name for those dense fine-grained igneous rocks, usually gray but often red or green, that to the naked eye show no crystals of minerals. Felsites generally are ancient lavas containing a high per cent of silica and are composed almost wholly of minute crystals of quartz and feldspar. The percentage of silica varies, and the relationship and probable origin of a felsite can be determined by analysis and examination with the microscope. Igneous rocks having a finely crystalline ground mass with visible crystals are said to have a felsitic ground mass, thus petrographers speak of felsite-porphyry. See Rock; Rhyolite; Trachyte.

Felt, Joseph Barlow, American historian: b. Salem, Mass., 22 Dec. 1789; d. there 8 Sept. 1869. He was graduated at Dartmouth College 1813, and was ordained Congregationalist minister, having churches in Sharon, Mass., and Hamilton, Mass. In 1836 he was appointed to classify the Colonial and State archives of Massachusetts. His 10 years' work at this task was invaluable to the State. Among his works are: 'Annals of Salem' (1827); 'History of Ipswich, Essex and Hamilton' (1833); 'Historical Account of Massachusetts Currency' (1839); 'Ecclesiastical History of New England' (1855–62); and 'Collections for the American Statistical Association on Towns, Population, and Taxation' (1847).

Felt, from Dutch *vilt,* a fabric made from wool, or wool and hair or fur, by rolling, beating, and pressure, generally with the use of lees or size. The process of felting is similar to that of fulling. The fibres of fur, hair, or wool are rough in one direction only, and thus they can glide among each other in such a way that when the mass is agitated the anterior extremities slide forward in advance of the body, or posterior half of the hair, and serve to entangle and contract the whole mass together. Articles of felt, such as rugs, carpets, clothing, and hats, have been made from remote antiquity, and are still made and widely used among various Asiatic peoples. Legend ascribes the invention of felt to St. Clement, who found that carded wool, placed in his shoes to protect his feet while on a pilgrimage, worked into a felt by the pressure and moisture; but it has a much earlier origin, being apparently known in Homer's time. The Saracens used it for tents and it was probably introduced into Europe at the time of the crusades. In Europe and America felt cloths are also made for several purposes, the finer kinds especially for carpets and table-covers, which may be dyed or printed and finished in various ways. In the machinery by which felt fabrics are produced, rollers with a rubbing and oscillating movement have generally an important action. The materials commonly used for felt hats are the furs of the rabbit and other animals, and the wool of sheep. The latter material is employed for common and medium hats, only the finer felt hats being made from fur. The hats, after being stiffened, are dyed. They now undergo the operation of blocking in order to give them their proper shape. Coarse varieties of felt are used for covering steam boilers and cylinders, steam-pipes, and otherwise as non-conductors. Asphalted felt is a coarse felt saturated with pitch, asphalt, or coal-tar, and used for covering sheds and other buildings, and a superior kind called inodorous felt is used for lining damp walls. Another kind is asbestos felt. See Hat.

Felton, Cornelius Conway, American classical scholar: b. Newbury, Mass., 6 Nov. 1807; d. Chester, Pa., 26 Feb. 1862. In 1834 he became professor of Greek literature at Harvard; in 1860 its president. His publications include many translations from German, French, and Greek, of which 'The Clouds' and 'The Birds' of Aristophanes are the most distinguished; also 'Familiar Letters from Europe' (1864); 'Greece, Ancient and Modern' (1867); 'Selections from Modern Greek Writers'; etc.

Felton, Samuel Morse, American railroad president: b. Philadelphia, Pa., 3 Feb. 1853. He is a nephew of C. C. Felton (q.v.). He early entered railway service, being employed by the Chester Creek Railroad 1868 and appointed assistant engineer of the Lancaster Railroad 1870. He worked his way upward on various roads, through the positions of chief engineer, general superintendent and general manager, to the vice-presidency of the Erie Railroad 1885–90. He also served as president of several southern railroads and became president of the Chicago & Alton Railway Company 7 Sept. 1899.

Feltre, Henri Jacques Guillaume Clarke, Duc de, äṅ rē zhäk gē yōm klärk dük dė feltr, a marshal of France: b. Landrecies, France, 17 Oct. 1765; d. Neuviller, France, 28 Oct. 1818. In 1781 he entered the military school at Paris, and was afterward imprisoned during the Revolution. He was subsequently employed by Carnot; in 1807 he became minister of war and was created Duc de Feltre. Though indebted to Bonaparte for his dukedom, he contributed toward the restoration of the Bourbons, by whom, in 1816, he was created marshal of France.

Felucca, fē luk'ä, a class of small merchant-vessels used in the Mediterranean. They have two masts, carrying lateen sails, and frequently have a rudder at each end. Formerly feluccas were also employed in war and piracy.

Female Rhymes (Fr. *rimes féminines*), double rhymes, or rhymes in which two syllables, one accented and the other unaccented, correspond at the end of each line. They are so called because they end in a weak or feminine syllable; thus, fable, table; motion, notion, are female rhymes.

Femern, fā'mĕrn, or **Fehmarn,** fā'märn, an island in the Baltic; taken from Denmark in 1864 and now part of Sleswick-Holstein, Germany. Area, 70 square miles; surface, level; soil, fertile, producing corn. Cattle are abundant. The inhabitants are mostly engaged in fishing, and agriculture. Large quantities of stockings knit by hand are exported. Pop. 9,900.

Femgerichte. See Vehmgerichte.

Femur, fē'mur, the large bone of the thigh. The femur is the chief supporting bone of the lower limbs and is in man the main organ of locomotion, for the larger muscles of the thigh and hip are attached to it. It is the largest and longest bone of the body. The upper extremity includes a head, neck, and two bony protuberances which give attachment to the muscles rotating it. The head fits into the socket in the hip-bone, making a ball-and-socket joint. (See Hip-Joint.) It is this joint that so frequently becomes affected in tuberculosis, resulting in deformities, and also at this joint that the dislocation of the femur takes place. The main shaft of the femur is nearly circular above; below, it is somewhat flattened, and running throughout its entire posterior surface there is a rough ridge to which muscles are attached. The lower end of the femur is enlarged, and has two surfaces to articulate at the knee with the tibia and fibula of the leg. These are known as the internal and external condyles, the external one being the broader, the internal the narrower and more projecting behind and to the sides. The upper portion of the front surface of the lower end of the femur is grooved to receive the patella or kneecap. The femur averages about 18 inches in the male, and is about one inch shorter in the female. It is inclined inward at an agle of about nine degrees in the male. In the female, by reason of the comparatively broader pelvis, the angle of the femur inward is greater. Consult: Gerrish, 'Human Anatomy' (1902). See Leg; Skeleton.

Fen, a place overflowed with water, or abounding with bogs, as the bogs in Ireland, the fens in Lincolnshire, Kent, and Cambridgeshire. These fens abound in duck, teal, mallards, pike, eels, etc., and an herbage that is very nourishing to sheep and cattle. The soil of fen lands is generally black and rich to a depth of two or three feet.

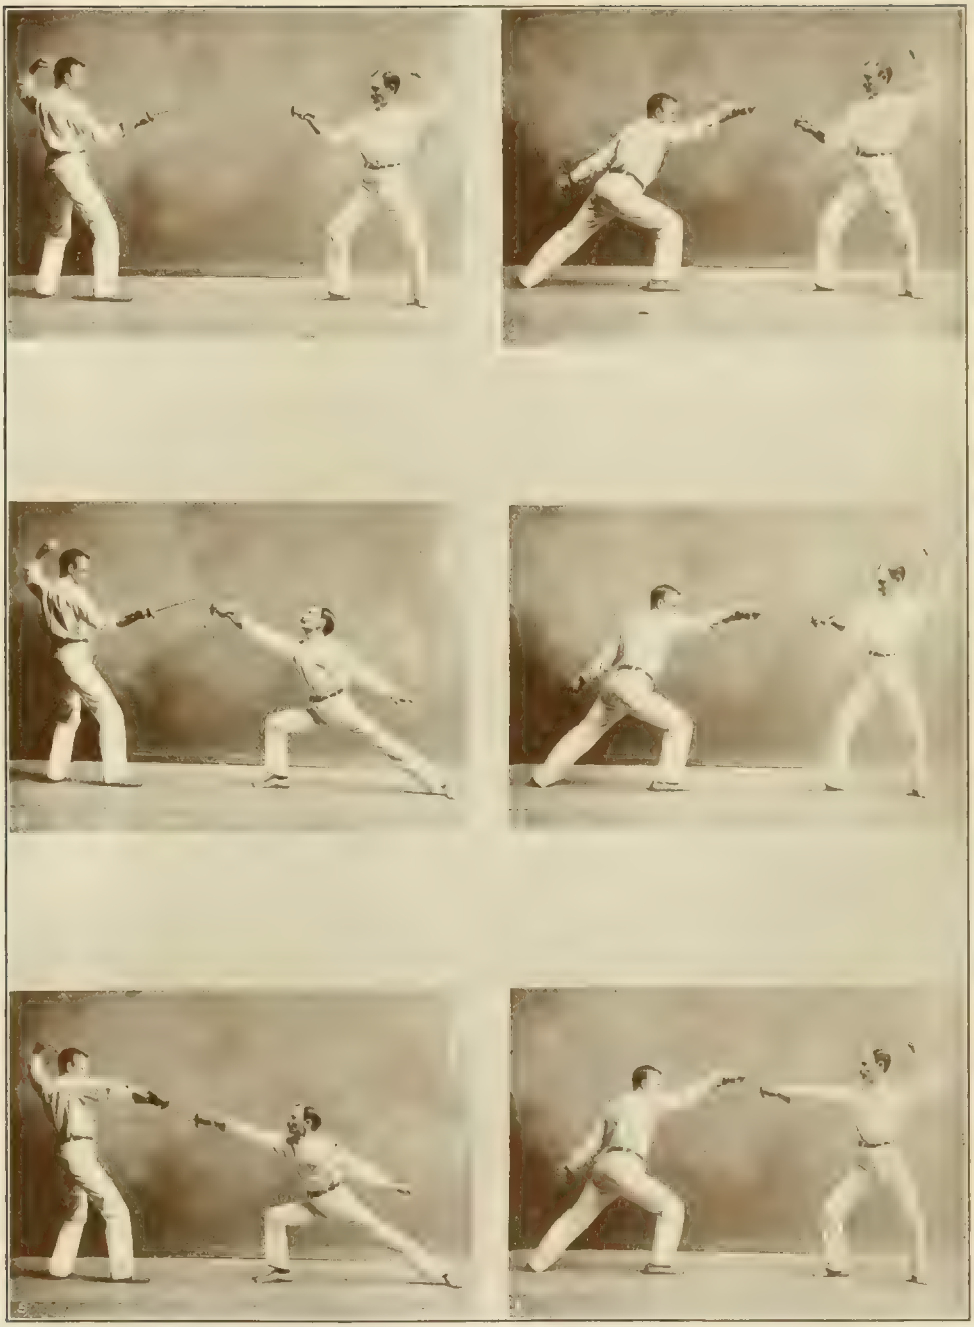
Fence Lizard. See Sceloporus; Swift.

Fence-viewers, town officers in New England to supervise the erection and repair of fences along the highways, or of boundary fences between private owners if called upon by either party. In early colonial days they had other duties also, including that of building inspectors.

Fences, continuous lines of obstacles artificially interposed between one portion of the surface of the land and another for the purpose of separation or exclusion. The kind of obstacle or material varies according to the articles to be excluded, confined, or separated, and the nature of the soil and situation. All fences are either live or dead, or a combination of these. Live fences are hedges, that is, rows of trees or shrubs, such as hawthorn, crab, blackthorn, holly, beech, box, etc., planted close together, and pruned on the sides. Dead fences are stone walls, structures of wood or iron, or mounds of earth, or ditches. Iron or wire fences are now in common use and vast tracts of waste land in this country are enclosed in this manner. Strong wires are stretched on posts firmly secured in the ground at from 100 to 200 yards distance from each other; a number of lighter posts are put in at 4 to 6 yards distance; when the wires are stretched they are fixed to the smaller posts by staples if the posts are of wood, or threaded through if of iron. The snake fence, also called rail fence and stake and rider fence, is made of split rails laid zigzag, with the ends resting on each other, supported by posts in pairs driven into the ground. A ring fence is one which completely encircles an estate. The height of fences is regulated by statute in the United States, the general height being four feet, although in some States it is four and a half feet. The practice of fencing has provided the language with striking figures of speech. «To be on the fence,» is a phrase used of a man who does not commit himself to any political party or take sides in any question. «To repair one's fences,» or «to look after one's fences,» is a phrase used in the United States for the efforts made by a politician to further his own interests, especially among his constituents.

Fencing, the art of attack and defense, with any weapon having either a point or an edge. In the general acceptance of the word, it means the use of the sword or foil, particu-

FENCING.



1. On Guard.
2. Attack and Parry of Quarte.
3. Attack and Parry of Tierce.
4. Attack and Parry of Septime.
5. Attack and Parry of Seconde.
6. A Riposte in Seconde, after a Parry of Tierce.

larly the latter. All swords may be divided into two general classes, small swords and broadswords; the former being one with which the attack is delivered with the point only, the latter one that has a cutting edge.

The foil used in fencing represents the small sword. The earliest swords of which there are any authentic records were those of the Assyrians and Greeks. They were straight or leaf-shaped, and made of bronze. The swords of the Romans were of steel, short, straight, and double-edged.

Light armor was worn by both the Greeks and the Romans, and a shield was carried for defense. During the Middle Ages when complete armor was worn, the sword was a long, heavy weapon used for striking blows, reliance being placed entirely upon the armor for defensive purposes.

When, after the invention of gunpowder, armor began to be discarded, it became evident that some other means of defense must be discovered, and it was in meeting this need that the art of fencing came into existence. The Italians were the first to recognize the fact that the point was more deadly than the edge, and that a thrust could be delivered more quickly than a blow, and to them belongs the credit of laying the foundations of the present school of fence. They invented the rapier, a long, straight sword having a cup-shaped guard with quillons, which was the parent of the small sword and foil. The early rapier was a weapon of offense only, parries being made with a dagger held in the left hand, or the point avoided by a leap aside. Camillo Agrippa of Milan was the first man to divide the body into four parts and to assign a definite guard to each. Agrippa published a book in 1553 explaining his system, which is said to have been illustrated by Michelangelo.

When daggers ceased to be worn, the cloak wrapped around the left arm was used in parrying. Later as the art of fence became better known, even the cloak was discarded, and the sword became a weapon of defense as well as offense.

While the Italians were building up their school on practical lines, the Spaniards invented a most complicated system of fence based on mathematical and geometrical principles. It was, however, of little use in actual fighting save that it taught coolness. The French and English were both followers of the Italian school, rapier play being introduced into England during the early part of Queen Elizabeth's reign. During the 18th century, the rapier, which had been constantly growing lighter, was replaced in France by the small sword, a weapon almost as light as our modern foil. The Italians, however, still clung to their ancient weapon and hence arose the two rival schools of fence, the French, and the Italian. Fencing masks also came into use at this time.

Broadsword play in some form or other was in existence during the periods of both the rapier and small sword and did not differ in its essential features from the system in use to-day. The Scots have always been especially noted for their dexterous use of the claymore, a species of heavy broadsword.

The French foil used in fencing consists of a quadrangular-shaped blade about 33 inches long, mounted in a slightly curved handle, and having either a bell-shaped or ring guard. The blade is divided into two imaginary parts, the part nearest the point being termed the "feeble," that nearest the guard the "forte." Parries are made by opposing the forte of one blade to the feeble of another. The foil is held in the right hand with the fingers underneath, the thumb extended along the upper part of the handle and nearly touching the guard. The thumb and forefinger direct the blade, the grasp of the other fingers being tightened or relaxed as occasion requires. In coming "on guard" the fencer raises his hand to the height of his breast, curves his arm so that his elbow will be about six inches from his body, and places the point of his foil on a level with his adversary's eye. At the same time he places his feet at right angles, about 12 inches apart, with the right foot in front, bends his knees, keeping the weight of the body slightly more on the left leg than on the right, and curves the left arm so that the hand will be behind the head. For fencing purposes, the body is divided into inside and outside, and high and low lines; an inside line being one to the left of the blade, an outside line one to the right of it; a high line one above the hand and a low line one below it. The high inside lines are termed Prime and Quarte, the low ones Septime and Quinte. The high outside lines are Tierce and Sixte, the low ones Octave and Seconde. All attacks, no matter how complicated, must eventually be delivered in one of these lines. For each attack there is a simple and a counter parry. Simple parries are made by turning aside the opposing blade in the line in which the attack is delivered; counter parries are made by circling round the blade and carrying it off in the line from which the attack began. To deliver an attack, the right hand is raised quickly to the height of the face, the right arm straightened, and the point directed against the place to be attacked. At the same time, the left leg is straightened, the right foot advanced, and the left hand dropped to a position about four inches above the left knee. This movement is termed the "Lunge."

Whenever fencers are in the position of guard opposing each other, they are said to be "engaged." Carrying the blade into another line is called "disengaging." An opening for an attack is made by feinting in one line and attacking in another, by forcing the blade aside, or by a combination of these movements. After a parry, a fencer delivers a return thrust termed a "Riposte," with which he endeavors to hit his opponent before he can recover his guard.

Hits only count when the point is placed squarely on the jacket between the neck and the hip. Disarming does not count and is not now practised to any great extent. The Italian foil is a trifle longer than the French one and has a straight handle, a bell guard and quillons. It is held by hooking the first and second fingers of the right hand around the quillons, the other fingers being tightly grasped around the handle, while the thumb is placed over the flat piece of the blade which is between the guard and its crosspiece. Further rigidity of the grasp is often assured by binding the foil tightly against the wrist with a long piece of tape. When on guard, the right arm is nearly straight, on a line with the shoulder, with the point directed at the opponent's chest. The body is always more effaced (turned away from the opponent) in the Italian school than in the French. The Italians divide the body into eight lines, as do the French, but as a general rule they use only four of them (quarte, tierce, septime and seconde) in making their attacks. Their parries are made more forcibly than those of the French; in some of them the movement of the forearm being very pronounced. The Italians fence much more vigorously than do the French and have a number of startling tricks, such as dropping under, or stepping away from the opposing blade, which they have retained from their old rapier play. The dueling sword is a heavier kind of foil, having a triangular blade and a large bell guard. It is used in nearly the same manner as a foil, but a hit may be made with it upon any part of the person.

In the use of the broadsword the attack is delivered with the edge rather than with the point. A limited number of thrusts can be made with it, but it is primarily a cutting weapon. The swords used for this kind of fencing are of various weights and shapes, the majority of them, however, are of the sabre model, with blunted edges and rounded points. Wooden singlesticks are also used. In assuming the position of guard the sword is held in the right hand with the thumb extended along the back of the grip, the edge to the right, with the hand at the height of the breast. The positions of the body and the feet are the same as in foil fencing, but the left hand is placed at the small of the back instead of behind the head. Attacks with the broadsword are made by giving a cutting blow with the edge. Cuts are made for the head, cheek, chest, girdle, flank, thigh, leg and arm. Thrusts with the point may also be made at the body. Cuts are parried with the edge; thrusts, with the back of the blade.

The student corps of Germany have a system of fence with a long straight sharp sword called a *schläger,* which differs from sabre play, in that the cuts are directed solely against the head. In this kind of fencing, masks are not worn, the eyes, ears, and throat, alone being protected, the sword arm is heavily padded and the blows are made with a wrist movement only.

The Japanese have a method of sword play which differs greatly from any of the present European systems. Their sword is a weapon some two and a half to three feet in length, having a heavily backed blade, a very sharp edge, a long handle, and a small protecting guard. It is wielded with both hands, the right hand being placed close to the guard and the left hand grasping the end of the grip. The first two fingers of both hands control and direct the blow, the grasp of the other fingers being tightened or loosened as occasion requires. The edge is generally kept downward while on guard. Cuts are made for the head, wrist, and waist, and thrusts for the throat and abdomen. A marked peculiarity of Japanese fencing is that parries are always made with the back or side of the blade, never with the edge. Bamboo swords are used for practice.

The bayonet attached to the end of a rifle makes a formidable weapon which is wielded in the same general manner as the small sword. In the position of guard, however, the left foot is in front, and the piece is grasped at the small of the stock, with the right hand, and at the balance with the left. When employed against cavalry the footman endeavors if possible to attack the horseman from the left side.

Among the famous fencers of the past four men stand out pre-eminently. These were the Chevalier de Saint Georges; the Chevalier d'Eon de Beaumont; Henry Angelo; and Jean Louis; all of whom lived during the latter part of the 18th or the early part of the 19th century, and were renowned for their great skill at fence. The prominent fencing masters of the present day are Mérignac, Prévost and Rouleau of the French school; and Conte and Pini of the Italian school. In the United States Gousky, Senac and Rondelle are well known masters. Contests for the amateur fencing championship of America are held annually under the auspices of the Amateur Fencers League of America.

FRED GILBERT BLAKESLEE,
Late Swordmaster 1st Regiment, Connecticut National Guard.

Fen'dall, Josias, colonial governor of Maryland: b. England about 1620. He was governor of Maryland 1656–60, and received a large landed estate from Lord Baltimore. He was superseded by Calvert, and was heavily fined and banished for sedition 1681.

Fénelon, François de Salignac de la Mothe, frän-swä dė sä-li-nyäk dė lä mōt fān lōn, French missionary: b. 1641; d. 1676. He was a half-brother of Archbishop Fénelon (q.v.). He emigrated to Quebec in response to Bishop Laval's appeal for missionary reinforcements, and being a Sulpician established a mission of his order on the north shore of Lake Ontario. In 1674 he offended the choleric Frontenac, governor of New France, by a sermon, was summoned before the council and ultimately felt himself compelled to leave for Europe. He was forbidden by the king to return to Canada.

Fénelon, François de Salignac de la Mothe, French prelate: b. Château de Fénelon, Périgord, France, 6 Aug. 1651; d. Cambray 7 Jan. 1715. He was educated at Plessis College in Paris, and at the seminary of St. Sulpice, where he received holy orders in 1675. In 1678 he was appointed head of an institution, then newly organized in Paris, for the reception of women converts to the Roman Catholic faith; and the success with which he there discharged his duties led to his appointment as head of a mission to Saintonge for the conversion of the Huguenots. In 1689, Louis XIV. entrusted to him the education of his grandsons, the dukes of Burgundy, Anjou, and Berri; and in 1694 he was created archbishop of Cambray. A theological dispute with Bossuet, his former instructor, terminated in the condemnation of Fénelon's side of the controversy by Pope Innocent XII., and his banishment to his diocese by Louis XIV. To the Pope's decision Fénelon unreservedly and humbly submitted.

His works in philosophy, theology, and the belles-lettres have immortalized his name. He was familiar with the best models of ancient and modern times, and his mind was animated by a mild and gentle spirit of benevolence. His style is fluent and pleasing, pure and harmonious. His most celebrated work is 'Les Aventures de Télémaque,' in which he endeavored to exhibit a model for the education of a prince. It was carried off and published by a valet employed to transcribe the manuscript. On the appearance of this work Louis manifested displeasure toward Fénelon, conceiving this historical romance to be a satire on his reign, and forbade the completion of the printing. Some malicious persons pretended, what Fenelon himself never thought of, that Calypso represented Madame de Montespan, Eucharis Mademoiselle Fontanges, Antiope the Duchess of Burgundy, Protesilaus Louvois, Idomeneus the exiled King James, and Sesostris Louis XIV. Among his other works are: 'Traité de l'Education des Filles'; 'Traité du Ministère des Pasteurs'; 'Explication des Maximes des Saintes'; 'Dialogues on the Eloquence of the Pulpit'; 'Demonstration of the Existence of God'; 'On the Temporal Power of the Mediæval Popes.' See Ramsay, 'Vie de Fénelon' (1725); Bossuet, 'Histoire de Fénelon' (1808); Gosselin, 'Histoire Littéraire de Fénelon' (1843); Butler, 'Life of Fénelon' (1810); Lamartine (1854); Roy, 'Histoire de Fénelon' (1842); Werfer, 'Leben des Fénelon' (1852); Gandar, 'Fénelon et son Temps' (1864); Lear, 'Fénelon, Archbishop of Cambrai' (1876); Crausle, 'Fénelon et Bossuet' (1895); Sanders, 'Fénelon: His Friends and His Enemies' (1901); Saint Cyres, 'François de Fénelon' (1901).

Fenelon Falls, Canada, township in Victoria County, province of Ontario. A waterfall 300 feet wide, 21 feet high, is the chief attraction of the place. The river affords facilities for the transportation of lumber, in which the vicinity abounds. Pop. 1,150.

Fenestra'tion, in architecture, is, in contradistinction to columniation, the system of construction, mode of design, and arrangement of windows in a building.

Fenians, a name said to be derived from Fionn or Finn, an Irish hero of the 2d century, assumed in recent years by those Irish who formed a brotherhood in their own country and in America, with the intention of delivering Ireland from the sovereignty of England, and establishing an Irish republic. About the end of 1861 the Fenian Brotherhood was regularly organized in America; and its chief council, consisting of a "head-centre" and five other members, which had its seat at New York, soon had branches in every State of the Union; while at the same time large numbers joined the cause in Ireland. The close of the American Civil War, when large numbers of trained Irish soldiers who had taken part in the war were released from service, was thought to be a convenient time for taking some decisive steps. Two risings were planned in Ireland, but they were both frustrated by the English government, which had received timely information. The first, in September 1865, was prevented by the seizure of the office of the 'Irish People,' the Fenian journal published at Dublin, in which papers were found which revealed to the government the secrets of the conspiracy, and which led to the capture of a number of suspects. The second, in February 1866, was suppressed by the suspension of the Habeas Corpus Act in Ireland.

An invasion of Canada was attempted in the same year. The advocates of Ireland's independence counted upon aid from the veterans of the Civil War, who were incensed at England's attitude toward the United States during the war. In this they were not disappointed; as among the trained men who were under command of Gen. Sweeney, himself an ex-officer of the United States army, there were many men not of Irish blood or lineage. The troops under Gen. Sweeney are estimated to have been at least 35,000 in number; but so well was the recruiting done that reserve forces who never went to the frontier numbered about 200,000. Gen Sweeney's men, in May 1866, were stationed at various points on the frontier from Lake Erie to Lake Champlain; at St. Albans, Vt., under Gen. Spear; at Rouse's Point, N. Y., under Gen. Reilly; at Malone, N. Y., under Col. Michael C. Murphy (q.v.), and around Buffalo, under Gen. John O'Neill (q.v.). Large quantities of arms and ammunition were sent north, a sufficient amount for 50,000 men; but the United States officials hearing of the expected raid, seized the consignment of arms addressed to suspected Fenians, and when the troops arrived on the frontier they were powerless because of lack of arms. An attempt was made to regain them, but the officers were arrested by the United States government. Gen. O'Neill invaded Canada by way of Fort Erie and two battles followed, in both of which O'Neill was successful. One, known as the "Battle of Ridgeway," occurred 1 June 1866. Reinforcements not arriving as expected, O'Neill abandoned the place and returned to the American side. He, his staff, and men were captured by the United States gunboat Michigan. The whole movement was crushed at that time by the United States forces under Gen. Meade, who acted under government instructions in accordance with the treaty between the United States and England. On 18 Sept. 1867 occurred, in England, the release by force of prisoners from a prison van which was conveying Kelly, the Fenian chief, and Deasy, his assistant, to Manchester prison. (See MANCHESTER MARTYRS.) In 1870 and 1871 another and unsuccessful attempt was made to gain a foothold in Canada. Various crimes and attempted crimes against the English government and anti-Home Rule leaders have been charged against the Fenians; but they were repudiated and denounced by the Fenians themselves, and attempts to prove them guilty have failed. Various organizations have taken up the cause for which the Fenians labored, and other methods have been used to secure some form of self-government for Ireland. (See HOME RULE.) Consult: Sullivan, 'Story of Ireland.'

Fenn, George Manville, English novelist: b. Westminster 3 Jan. 1831. His earliest literary ventures were short sketches published in 'All the Year Round, Chambers' Journal,' and 'Once a Week' (of which he became proprietor in 1873). In 1867 he published 'Hollowdell Grange,' a story for boys, which has since been followed by a long series of excellent and highly popular tales and novels, many of them boys' stories. The following may be specially mentioned: 'Bent, not Broken' (1867); 'The Parson o' Dumford' (1879); 'Eli's Children'

(1882); ‹The New Mistress› (1883); ‹Double Cunning› (1886); ‹The Master of the Ceremonies› (1886); ‹The Man with a Shadow› (1888); ‹A Double Knot› (1890); ‹The Mynns Mystery› (1891); ‹King of the Castle› (1892); ‹In an Alpine Valley› (1893); ‹High Play› (1898). Among his boys' books are: ‹In the King's Name›; ‹Nat the Naturalist›; ‹Bunyip Land›; ‹Menhardoc›; ‹Patience Wins›; ‹Brownsmith's Boy›; ‹Commodore Junk›; ‹The Crystal Hunters›; ‹The Grand Chaco›; ‹Blue-jackets›; ‹Fire Island.› Mr. Fenn has also produced, either alone or in collaboration, several works for the stage.

Fenn, Harry, American artist: b. Richmond, Surrey, England, 14 Sept. 1838. He removed to the United States in 1856 and has achieved great success as an illustrator of books. He was one of the founders of the American Water Color Society. Some of his best work is contained in ‹Picturesque America›; ‹Picturesque Europe›; and Picturesque Palestine.›

Fenn, William Wallace, American Unitarian clergyman: b. Boston 12 Feb. 1862. He was graduated at Harvard 1884 and at the Harvard Divinity School 1887, and was ordained to the ministry in 1887. He has since had charge of churches in Pittsfield, Mass., (1887–91), and Chicago (1891–1901). He was lecturer on biblical literature in Meadville Theological School 1892–1901 and in the last named year was appointed professor of systematic theology in Harvard Divinity School. He has published: ‹Lessons on Luke› (1890); ‹Lessons on Acts› (1894); ‹The Flowering of the Hebrew Religion› (1894); ‹Lessons on Psalms› (1900).

Fen'nec, a small desert animal (*Fennecus zerda*) found in the Sahara, which looks like a diminutive fox. It is of a pale creamy yellow color, harmonizing well with its sandy habitat; its breast is white, and the tail tipped with black. It is a graceful little animal, about 15 inches long, with a bushy tail, about 7 inches in length; and its small face and large erect ears give it an expression of attentive hearkening for unseen foes. It burrows into the sand, and can dig so rapidly as to escape pursuers. It is, like most of its kind, nocturnal in habits, searching for water and its food — small birds, mice and insects — after the sun sets, spending the day curled up in its burrow.

Fennel, a plant of the genus *Fœniculum* of the carrot family. The plant is native of parts of England, and is common from New Jersey, through Pennsylvania to Virginia and Louisiana, as a fugitive from cultivation. The plant has umbels of small yellow flowers, and finely divided leaves. It grows to the height of three or four feet. In its natural state the seeds are intensely acrid. By cultivation this acridity is lost, and an agreeable taste and flavor acquired. In European cookery the leaves are often used as a seasoning, or as an accompaniment of fish. A smaller species, sweet or Italian fennel (*F. dulce*), is commonly cultivated on the continent of Europe, and is used in salads, soups, etc. Several other species of fennel are known, some of which are admired for their pungency. The seeds (or "half fruits") are flat on one side and convex on the other, seldom exceeding one fourth of an inch in length. They have a fragrant odor, and warm, pleasant taste. Their infusion in boiling water is used as a carminative, and having no actively exciting qualities, is employed to disguise by its pleasant aromatic nature the flavor of disagreeable medicines, as senna and rhubarb. The oil of fennel is obtained from the seed. It is yellowish, somewhat thick, with an aromatic odor and sweet taste. It is lighter than water, and solidifies with moderate diminution of temperature.

The seed from which the volatile oil is obtained is used in medicine as an aromatic stimulant and as a carminative. It is useful in infantile diarrhœa with excessive fermentation, and as a flavoring vehicle for many medicines.

Fenollo'sa, Ernest Francisco, American writer: b. Salem, Mass., 18 Feb. 1853. He was educated at Harvard, was professor of political economy and philosophy at Tokio University, Japan, 1878–80, and of philosophy and logic 1880–6; professor of æsthetics in the Tokyo Fine Arts Academy 1887–90; and curator of the oriental art department, Boston Art Museum 1890–6. Since 1897 he has been professor of English in the High School of Tokyo. He has published monographs on art and ‹The Discovery of America and Other Poems› (1893).

Fenollosa, Mary McNeil, American writer: b. Alabama. She was married to E. F. Fenolosa (q.v.), 28 Dec. 1865, and has since published ‹Out of the Nest: a Flight of Verses› (1899); ‹Children's Verses on Japanese Subjects›; ‹Hi roshige.›

Fenton, Elijah, English poet: b. Shelton, Staffordshire, 20 May 1683; d. East Hampstead, Berkshire, 13 July 1730. He studied at Cambridge, but becoming a non-juror he was obliged to leave the university, after which he accompanied the Earl of Orrery to Flanders as private secretary. Some years later Fenton became associated with Pope, who was then undertaking his version of the ‹Odyssey,› and was in quest of assistants. According to Dr. Johnson, Fenton translated the 1st, 4th, 19th, and 20th books of that poem. In 1723 a tragedy entitled, ‹Mariamne,› which he brought out, had an immense success, and gained him more than £1,000. In 1727 he published a new edition of Milton's works, to which he prefixed a brief but elegant life of the author. This was soon followed by a fine annotated edition of Waller.

Fenton, Ferrar, English author: b. Lincolnshire 1832. Among other works he has published: ‹Seven Years of an Indian Officer's Life›; ‹Poems from the Persian›; ‹The New Testament in Modern English›; ‹The Five Books of Moses, direct from the Hebrew, in Modern English with Critical Notes›; ‹St. Paul's Epistles in Modern English.›

Fenton, Reuben Eaton, American statesman: b. Carroll, Chautauqua County, N. Y., 4 July 1819; d. Jamestown, N. Y., 25 Aug. 1885. He was admitted to the bar in 1841; was elected to Congress in 1852, and there opposed the further extension of slavery. In 1856 he was again elected to Congress, where he remained till 1865, when he resigned to become governor of New York, in which office he served for two terms. In 1869–75 he sat in the United States Senate, and in 1878 was chairman of the United States Commission to the International Monetary Conference in Paris.

Fenton, England, town of Staffordshire, near and to the southeast of Stoke-upon-Trent. The chief industries are china and earthen-ware manufacture, brick making, coal mining and iron founding. Pop. (1901) 22,742.

Fen'ugreek, the seed of *Trigonella fœnum-græcum,* a plant of eastern Europe and western Asia and which spreads throughout the Mediterranean basin. It is a member of the clover family, and has been used like clover for many years as a fodder plant. The seed contains an aromatic essential oil, and has been very extensively used as a seasoning. In medicine its use has practically been abandoned, although the seed has unquestionably many excellent properties, its food value alone being considerable. It is still very extensively used in veterinary practice.

Fen'wick, Ethel Gordon, English nurse: b. 26 Jan. 1857. She married Dr. Bedford Fenwick in 1887. She has been connected with various English hospitals as nurse, and is a member of many nurses' associations. She was president of the British Nursing department at the Chicago World's Fair, receiving two medals on that occasion; was awarded the Red Cross medal in the Græco-Turkish war 1899, and was president of the International Nurses' Congress at Buffalo 1901. She is the editor of 'The British Journal of Nursing.'

Fenwick, George, American colonist: b. England about 1602; d. 15 March 1657. He came to America in 1636 to take charge of the plantation of Saybrook, so called after Lords Say and Brook, who, with others, in 1632 had procured a patent for the territory from Robert, Earl of Warwick. Returning to England, he came back again in 1639, and from that time, as one of the patentees, and agent for the others, superintended and governed the settlement of Saybrook till 1644, when he sold its jurisdiction and territory to the Connecticut colony, as his associates had given up their contemplated removal to America. He afterward returned to England, where he was appointed one of the judges for the trial of Charles I., but did not act in that capacity. He served in Cromwell's army in Scotland in 1650.

Fenwick, or **Fenwicke, John,** American colonist: b. England 1618; d. 1683. He was a Quaker and settled at Salem, N. J., in 1675 with a colony of Quakers. Disputes arose with Gov. Andros of New York, and Fenwick was arrested and remained two years in prison, being released on parole. His land grants passed to the possession of others during his life, and he died in poverty.

Fenwick, Sir **John,** English conspirator: b. England about 1650; d. 28 Jan. 1697. He became major-general in the army, and was a member of parliament in 1677. He conspired with others against William III. and was accused of participation in the Assassination Plot in 1696. A bill of attainder being passed, he was executed for high treason, the last execution in Great Britain in consequence of attainder.

Feodor I., Ivanovitch, ē-vän'ō-vich fā'ō-dōr, Russian czar: b. 11 May 1557; d. 7 Jan. 1598. He began his reign in 1584, and being weak both in body and mind, assigned the government of his affairs to Godunoff, who seems to have managed them with dexterity and vigor. In his reign the peasants of Muscovy were converted into serfs and attached to the land. Previously they had enjoyed personal liberty. The conquest of Siberia was achieved by Godunoff, and many remarkable diplomatic relations with foreign courts were effected.

Feodor II., Alex'ievitch, Russian czar: b. 1589; d. 10 June 1605. He was the son of Boris Godunoff.

Feodor III., czar of Russia, and eldest brother of Peter the Great: b. 8 June 1656; d. Moscow 27 April 1682. He ascended the throne when only 19 and evinced a strength of will and determination of character which, had he lived, might have anticipated the reforms which his younger brother subsequently effected. His reign is rendered memorable on account of his calling into his presence the Muscovite nobles, who desolated the country with broils about their claims of family precedence, and throwing the rolls of the Razriad or «Arrangement,» into the fire. The genealogical records, which did not relate to claims of precedence, were preserved and properly arranged in accordance with his will.

Feodosia, fā-ō-dō'sē-ä (ancient Caffa or Kaffa), Russia, town on the west angle of a magnificent bay in the southeast of the Crimea. The ancient Theodosia, from which the modern Feodosia takes its name, was founded at a very early period by a colony of Greeks from Ionia, and its site was probably not far from its modern namesake. From 1266 to 1474 or 1475 this town was in the possession of the Genoese, except for a short interval about the end of the 13th century, when it was held by the Venetians. While in the hands of the Genoese it was the seat of an extensive commerce with the East by way of Astrakhan and the Caspian Sea, and at that time it is said to have had a population of 80,000. From the Genoese it was taken by the Turks, and after that its prosperity rapidly declined. Much has been done for it since it came into the possession of Russia, and it is still one of the most important towns in the Crimea. Pop. (1897) 27,238.

Fer-de-lance, fār-dė-läñs, the lance-headed or yellow viper (*Lachesis lanceolatus*), a serpent native to northeastern South America, and one of the most terrible members of the rattlesnake family. It is ordinarily 3 to 4 feet in length when full-grown, and has no rattle, but the tail ends in a horny spine which is vibrated rapidly when the snake is excited. It has the general appearance and habits of the rattlesnake (q.v.), feeds upon small mammals, frogs and the like, and was long ago introduced into Martinique, Santa Lucia and a few other of the Antilles, as a means of devouring the rats which were a pest to the fields of sugarcane. It flourished and multiplied greatly, and has become greatly dreaded by all who work in the fields of those islands.

Feræ, fē'rē, wild animals; a term adopted by Linnæus for one of his orders of *Mammalia,* embracing a variety of carnivorous animals now scientifically reclassified.

Feræ Naturæ, fē'rē na-tū'rē («of a wild nature»), the legal name for beasts and birds that are wild or non-domesticated, as contradistinguished from those which are *domitæ naturæ,* that is, tame animals, such as horses, sheep, etc. The Roman law held such animals as naturally belonging to the first person who should take possession of them, but regarded the right of possession as continuing only as long as the possessor kept them in confinement. As soon as the animal escaped it again became common property, and might be taken possession of by any other person who could capture it, unless the animal had an *animum revertendi,* that is, an intention of returning, which it was to be presumed it had, if it had been trained to return to its master's property, and was in the habit of doing so. This principle has been adopted by both British and American law. When such animals as are classed as *feræ naturæ* make nests or burrows on any person's property, and have young, the young are held as belonging to this person as long as they are unable to fly or run away. Those persons who have the right of hunting, taking, or killing those wild animals which are included under the designation of game, have a qualified property in such animals as long as they continue within their liberty, but no longer. A person who keeps an animal indisputably *feræ naturæ* is responsible for any injury which it may do to the person or property of another. Consult: Schouler's 'Treatise on the Law of Personal Property' (1896).

Fer'dinand I. (surnamed «THE JUST»), king of Aragon: b. 1379; d. Igualada 2 April 1416. He was king of Aragon 1412–16, and was succeeded by Alfonso V.

Ferdinand II., king of Aragon. See FERDINAND V. OF CASTILE.

Ferdinand I., emperor of Austria: b. Vienna 19 April 1793; d. Prague 29 June 1875. He was a son of Francis I. and ascending the throne in 1835, continued to pursue the policy of his father, leaving the chief direction of affairs in the hands of Metternich (q.v.). In his reign, the republic of Cracow was annihilated, and a portion of it added to the empire. During the revolutionary war of 1848 he dismissed Metternich and made several concessions which were found insufficient. Vienna revolted in May, and Ferdinand at length retired to Olmütz, and on 2 Dec. 1848, abdicated, having no children, in favor of his nephew, Francis Joseph I.

Ferdinand I., German emperor: b. Alcalá, Spain, 10 March 1503; d. Vienna 25 July 1564. He was a brother of Charles V., after whose abdication in 1556 he took the title of emperor of Germany, although his claim to the title was not recognized by the electors till 1558. In 1526 or 1527 he became king both of Hungary and Bohemia, and after that period these two kingdoms remained attached to the empire. Ferdinand had been chosen king of the Romans in 1531. In 1559 he held a diet at Augsburg, in which the currency of the empire was regulated, and many religious grievances suffered by the Protestants were exposed. Ferdinand was of a mild and tolerant character, and in 1562 obtained from the Council of Trent several religious privileges for his subjects.

Ferdinand II., German emperor. b. Gratz, Styria, 9 July 1578; d. Vienna 15 Feb. 1637. He succeeded his uncle Matthias as emperor of Germany in 1619. His zeal was excited against every deviation from the decrees of the Council of Trent, and he firmly adhered to an anti-Protestant policy. The Bohemians, jealous of the privileges which they had secured from Rudolph, and of which they saw that Ferdinand was disposed to deprive them, declared that he had forfeited the Bohemian crown, which they offered to the Elector Palatine Frederick V., a step which lead to the outbreak of the Thirty Years' war. The support of the league, and of the Elector of Saxony, John George I., placed him firmly on the throne of Bohemia, where he vigorously pursued the Protestants, whose opposition to him was as much political as religious.

Ferdinand III., German emperor, son of Ferdinand II.; b. in Gratz, Styria, 11 (or 13) July 1608; d. Vienna 2 April 1657. He was made king of Hungary in 1625, of Bohemia in 1627, and succeeded his father in 1637.

Ferdinand I., king of Naples, illegitimate son of Alfonso I.; b. about 1424; d. 25 Jan. 1494. He succeeded his father in 1458. His false and cruel character provoked a civil war, in which John of Anjou took part with the barons, and the king was aided by the Pope Pius II., Sforza, Duke of Milan, and by Scanderberg. The king defeated his rival in 1462, and made peace; but breaking his word war broke out again. Again the king won, and established order by terror.

Ferdinand II., king of Naples, son of Alfonso II.; b. 26 July 1469; d. 7 Oct. 1496. He succeeded his father when the latter abdicated in 1495.

Ferdinand III., king of Naples. See Ferdinand V. of Castile.

Ferdinand IV., of Naples, and I., of the Two Sicilies: b. Naples, Italy, 12 Jan. 1751; d. there 4 Jan. 1825. He ascended the throne in 1759, and after the death of Louis XVI. he joined the coalition engaged in the general war against France (1793-6). The victory gained at Aboukir by Nelson again brought Ferdinand into a hostile attitude against the French, who summarily drove him from his kingdom in 1799. In the same year, however, his troops regained possession of the capital. In 1806 Ferdinand was again forced to abandon Naples, the crown of which Napoleon I. conferred first on his brother Joseph Bonaparte, and afterward on his brother-in-law, Murat (q.v.), Ferdinand, however, continuing to reign in Sicily under English protection. In 1814 the Congress of Vienna finally established Ferdinand as King of the Two Sicilies. Revolutionary movements, set afloat by the Carbonari (q.v.), compelled the establishment of a constitution, against the advice and interests of Austria, Russia, and Prussia; the first named power marched an army across the Po, defeated the Neapolitan army, and occupied Naples. Ferdinand who, refusing to sanction the liberal declarations of his subjects, had quitted his capital, was then reestablished, and ruled thenceforward with absolute power.

Ferdinand II., king of the Two Sicilies: b. Palermo 10 Jan. 1810; d. Naples 22 May 1859. He succeeded his father Francis I. 8 Nov. 1830. The new sovereign at first made some concessions to his subjects; but presently gave them to understand that henceforth his will was to be their only law, and that the least opposition to it would be followed by banishment or incarceration in a dungeon. This was no empty threat. Devoting much time to hunting, he left the government to be administered by favorites, and reserved his interference chiefly for occasions requiring the exercise of that mixture of obstinacy and energy which formed the leading feature in his character. After a succession of partial outbreaks, the revolutionary year of 1848 brought matters to a crisis, during which Ferdinand II. earned the nickname of "King Bomba," by bombarding his capital from the forts commanding it. At the commencement of the insurrection, which first broke out at Palermo, and threatened to extend over both divisions of the kingdom, Ferdinand issued a decree promising a constitution, but ultimately, when he had by main force re-established his ascendency, retracted all his promises and established one of the vilest despotisms which has disgraced modern times. Great Britain and France endeavored, by friendly remonstrance, to check him, and being only rebuked for presuming to interfere, testified their displeasure by withdrawing their ministers from Naples. This measure seems only to have made Bomba more resolute than ever to rule in his own way. He died leaving his dungeons crowded with the best and bravest of his subjects.

Ferdinand, titular king of Portugal: b. Vienna 29 Oct. 1816; d. Lisbon 15 Dec. 1885. He was a son of the Duke of Saxe-Coburg-Gotha, and married Maria de Gloria, Queen of Portugal, in 1836. The title of king was granted him in 1837, and after the queen's death, in 1853, he was regent till 1855, during the minority of his son Pedro. In 1869 he married an American singer, Eliza Hensla, whom he made Countess of Edla. He possessed not a little skill as artist and engraver.

Ferdinand I. (surnamed "The Great"), king of Castile and Leon: b. about 1000; d. Leon, Spain, 27 Dec. 1065. He was the second son of Sancho II., king of Navarre, and by the death of Bermudo, 1037, he became king of Leon. He then made war against the Moors, from whom he took several cities, and pushed his conquests as far as Portugal. He next declared war against his brother, Garcias III., king of Navarre, in which that prince lost his kingdom and his life.

Ferdinand II., king of Leon: d. 1188. He was the son of Alphonso VIII., and in a war with Portugal made the king, Alphonso Henriquez, prisoner. In the reign of this prince the military order of St. James was instituted, 1177, for the purpose of defending the dominions of the Christian powers against the Saracens.

Ferdinand III. (surnamed "The Saint"), king of Castile and Leon: b. about 1200; d. Seville, Spain, 30 May 1252. He was the son of Alphonso IX., and obtained the crown of Castile by the abdication of his mother, Berengaria, in 1217, and that of Leon by the death of his father in 1230. He took many places from the Moors, was canonized by Pope Clement X., and is regarded as the founder of the University of Salamanca.

Ferdinand IV., king of Castile and Leon: b. Seville 1285; d. 1312. He succeeded to the throne of Castile in 1295, at the death of his father, Sancho IV.

Ferdinand V. (surnamed "The Catholic"), king of Aragon: b. Sos, Aragon, 10 March 1453; d. Madrigalejo, Spain, 23 Jan. 1516. On 18 Oct. 1469 he married Isabella of Castile (q.v.) and thus brought about a close connection between Aragon and Castile, although both kingdoms continued to be governed separately, for Isabella allowed her husband no other share in the government of Castile than the privilege of affixing his signature to the decrees, and of uniting his arms with her own. With Ximenes they raised Spain to an eminence which she had never before attained. After a fierce war of 10 years they conquered Granada (1491), the only kingdom of which the Moors yet retained possession in Spain; but the most brilliant event of their reign was the discovery of America, for which Isabella had furnished the ships, and which made them sovereigns of a new world. (See Columbus.) This politic prince laid the foundation of the Spanish ascendency in Europe by the acquisition of Naples (1503), by means of his general Gonsalvo of Cordova, and by the conquest of Navarre (1512); but his policy was sometimes deceitful and despotic. These stains obscure the great qualities which made him the first monarch of his time. It was during his reign that the court of the Spanish Inquisition was established (1480). In 1492 he expelled the Jews from the kingdom, and banished the Moors in 1501. Two years after the death of his wife Isabella, which took place in 1504, he married Germaine de Foix. See Prescott, 'The Reign of Ferdinand and Isabella' (1837).

Ferdinand VI., king of Spain: b. 23 Sept. 1712; d. Villaviciosa, 10 Aug. 1759. He was the son of Philip V., and ascended the throne in 1746. He promoted the internal welfare of his country, reorganized the navy, encouraged manufactures, and by his judicious political conduct placed his elder brother on the throne of Naples, and another under the ducal canopy of Parma.

Ferdinand VII., king of Spain: b. San Ildefonso 13 Oct. 1784; d. Madrid 29 Sept. 1833. He was the eldest son of Charles IV. From the earliest years he manifested a strong dislike to the favorite Godoy, who ruled both the king and queen; and in 1807 was arrested as a conspirator. After the popular rising at Aranjuez, in March 1808, his father was forced to abdicate in his favor. A month later, having been induced to meet Napoleon at Bayonne, he himself abdicated in turn, placing the crown at the disposal of Napoleon, who at once gave it to his brother Joseph. Ferdinand was kept a prisoner at Valençay till 1813, when Napoleon offered to re-establish him on his throne. He returned to Spain in March 1814, having previously promised to maintain the constitution of 1812. In spite of his promise he annulled this constitution and dissolved the Cortes two months after his return. In consequence of this and of his arbitrary rule a military insurrection broke out 1 Jan. 1820. The rebels were at first successful, and Ferdinand was obliged to swear to the constitution of 1812; but having received support from Louis XVIII. of France, who sent an army to his aid, commanded by his nephew, the Duke of Angoulême, he was ultimately enabled to suppress the insurrection, and to make his authority once more absolute in Spain. Ferdinand was married four times, but only left one daughter, Isabella, by his fourth wife, Maria Christina of Naples. By a decree issued 29 March 1830, called the Pragmatic Sanction, he abolished the act of 1713, by which Philip V. had excluded women from the throne of Spain. He then left his crown to his daughter Isabella, to the exclusion of his brother, Don Carlos. It was during the reign of this king that the Spanish colonies in South America broke away from the mother country.

Ferdinand III., Joseph John Baptist, grand duke of Tuscany and archduke of Austria: b. 6 May 1769; d. Florence, Italy, 18 June 1824. He succeeded his father, the Emperor Leopold II., as grand duke of Tuscany, in 1790. He was the first sovereign to acknowledge the French Republic, and although compelled to join the first coalition against it, took the first opportunity of withdrawing. In spite of this he was, in 1799, at the time of the second coalition, deprived of his dominions, which, at the Peace of Lunèville, in 1801, were given to the Prince of Parma. He afterward received as compensation the duchy of Salzburg, in Germany, with the title of elector. In 1805 he exchanged Salzburg for the grand-duchy of Würzburg; in 1806 he joined the Confederation of the Rhine, and till 1813 remained a faithful ally of Napoleon. By the first Peace of Paris (30 May 1814) he recovered his hereditary dominions. See Inghirami, 'Storia della Toscana' (1843); Thayer, 'Dawn of Italian Independence' (1893); Tivaroni, 'Italia Durante il Dominio Austriaco' (1892-4).

Ferdinand IV., grand duke of Tuscany: b. 10 June 1835. He was a son of Leopold II., whom he succeeded in 1859, and in 1860 his country was incorporated with the kingdom of Sardinia and subsequently with the kingdom of Italy.

Ferdinand, duke of Brunswick, German field marshal: b. Wolfenbüttel 12 Jan. 1721; d. Brunswick 3 July 1792. Entering the Prussian service in 1740 he rose rapidly and became one of the famous commanders of the age. He was also noted for his patronage of science and art as well as for his many benevolences.

Ferdinand, Maximilian, prince of Bulgaria: b. Vienna 26 Feb. 1861. He is the youngest son of Prince Augustus of Saxe-Coburg, and was offered and accepted the rulership of Bulgaria in 1887. In 1896 Turkey recognized his election as ruler and urged the other interested powers to do so, and in April following, the acts of reconciliation and recognition were completed by his being received by the czar and the diplomatic corps at St. Petersburg.

Ferdinand, Victor Albert Meinrad, prince of Rumania: b. Sigmaringen, Prussia, 24 Aug. 1865. He is the second son of Prince Leopold of Hohenzollern and nephew of Charles I. of Rumania, and was declared heir presumptive to the Rumanian crown in November 1888. In the following March he was granted the title of Prince of Rumania and declared successor to the crown. He married Maria, eldest daughter of the Duke of Edinburgh, in January 1893.

Ferdinand, a noted figure in Shakespeare's 'Tempest.' He is the son of the King of Naples, and after being shipwrecked through the magic of Prospero, on the latter's enchanted island, falls in love with Prospero's daughter, Miranda.

Ferentino, fā-ren-tē'nō (ancient FERENTINUM), Italy, city in the province of Latium, six miles northwest of the town of Frosinone. It belonged to the Volsci, under whom it rose to be a place of considerable importance, and it still exhibits the remains of ancient walls, built of hewn stone without mortar. It is the see of a bishop. Pop. 9,096.

Feretory, fĕr'e-tō-ri, the bier or shrine containing the relics of saints borne in processions, which was usually done upon their feast days, as a token of gratitude in times of public rejoicing, or to obtain some favor in seasons of calamity. The type of a feretory is a coffin, but the form is usually that of a ridged chest, with a roof-like top. It was made of precious metals, wood, or ivory.

Ferghanah, or **Ferganah,** fĕr-gä'nä, a province, since 1876, of Russian West Turkestan, formerly the khanate of Kokand, lying among the western ranges of the Tian-Shan Mountains; area, 35,654 square miles, four fifths of which are mountainous, the Tchotkal Mountains being in the north, and the Ala-tau and the Trans-Ala-tau chain in the south. The rest of the province consists of the fertile irrigated plain of the Sir-Daria (Jaxartes), which traverses Ferghanah from northeast to southwest. The chief towns are Kokand, capital; Margelan, Namangan, and Andidjan. Pop., estimated, 1,560,411.

Fergus (fur'gus) Falls, Minn, city, county-seat of Otter Tail County; on the Red River, the Northern P. and the Great N. R.R.'s. It is in the heart of the "park" section of the State, being surrounded by prairie land and forests of pine and hardwood and the Park Region. It contains the Norwegian Lutheran College, high school, public library, State Hospital for the Insane, waterworks, electric lights, several banks and newspapers. The manufactures are flour, lumber, wagons, sleighs, woolen goods, furniture, brooms, etc. Pop. (1900) 6,072.

Ferguson, Adam, Scottish writer: b. Logierait, Scotland, 20 June 1723; d. St. Andrews 22 Feb. 1816. He was graduated at the University of St. Andrews in 1742; was professor of natural philosophy in Edinburgh University in 1759, and of mental and moral philosophy 1764-85; and was later professor of mathematics. He wrote: 'Institutes of Moral Philosophy' (1769); 'History of the Progress and Termination of the Roman Republic' (1782); 'Principles of Moral and Political Science' (1792), etc.

Ferguson, Henry, American educator: b. Stamford, Conn. He was graduated at Trinity College 1868, and entered Episcopal ministry 1873. He was rector of Christ Church, Exeter, N. H., 1872-8, and rector of Trinity Church, Claremont, N. H., 1878-80. Since 1883 he has been professor of history and political economy at Trinity College. He has published: 'Four Periods in the Life of the Church,' 'Essays on American History.'

Ferguson, James, Scottish physicist: b. Keith, Banffshire, 25 April 1710; d. London 16 Nov. 1776. As soon as his age would permit he was employed by a farmer to tend his sheep, in which situation he acquired a knowledge of the stars and constructed a celestial globe. This extraordinary ingenuity becoming known he was enabled to obtain instruction in mathematics and drawing, in which latter art his improvement was so rapid that he drew portraits in miniature, by which employment he supported himself for some years. In 1743 he went to London, where he published astronomical tables and lectures and lectured on experimental philosophy. In 1763 he was chosen a Fellow of the Royal Society, without the usual fees. His chief works are: 'Astronomy Explained on Sir Isaac Newton's Principles' (1756 — many editions); 'Lectures on Select Subjects in Mechanics, Hydrostatics, Pneumatics, and Optics' (1760); 'Analysis of a Course of Lectures on Mechanics, Pneumatics, etc.' (1763); 'Young Gentleman's and Lady's Astronomy' (1768); 'Introduction to Electricity' (1770); 'Select Mechanical Exercises' (1773); 'The Art of Drawing in Perspective' (1775). Most of his works were very popular.

Ferguson, James, American astronomer and civil engineer: b. Perthshire, Scotland, 31 Aug. 1797; d. 26 Sept. 1867. In his infancy he was brought to New York (1800), and on reaching manhood worked as an assistant engineer in the excavation of the Erie canal (1817-19). The three following years he was employed as assistant surveyor to the boundary commission appointed to carry out the provisions of the Treaty of Ghent. From 1822 to 1827 he was astronomical surveyor on the same work. The pursuit of practical astronomy occupied his later life, and as assistant astronomer of the United States Naval Observatory, he discovered several asteroids, and was a frequent contributor to scientific magazines.

Ferguson, Lady Mary Catharine, Irish writer: b. Stillorgan County, Dublin, Ireland, 1823. She was married in 1848 to Sir Samuel Ferguson (q.v.). She has published 'The Irish Before the Conquest' (1867); 'Life of William Reeves' (1893); 'Sir Samuel Ferguson in the Ireland of His Day' (1896), and edited her husband's works (1887-97).

Ferguson, Patrick, British soldier and inventor of the breech-loading rifle: b. Pitfour, Scotland, 1744; d. King's Mountain, S. C., 7 Oct. 1780. Entering the army in 1759, he served in Germany and Tobago. In 1776 he patented his rifle, firing seven shots a minute, and sighted for ranges of from 100 to 500 yards; and with it he armed a corps of Loyalists, who helped at the battle of Brandywine (1777) to defeat the American army. He himself had a chance there of picking off an officer, but "let him alone, disgusted with the idea of firing at the back of an unoffending individual, who was acquitting himself very coolly of his duty." Next day he learned that the officer was Washington. Three years later, Ferguson fell, defending King's Mountain, S. C., with 800 militia, against 1,300 Americans.

Ferguson, Robert (surnamed "The Plotter"), Scottish conspirator: b. near Alford, Aberdeenshire, about 1637; d. 1714. He went to England about 1655 and in 1662 was ousted as a Presbyterian from the Kentish vicarage of Godmersham. He played for 10 years a leading part in every treasonable scheme against the last two Stuart kings, and twice had to flee the kingdom. But after the Revolution he changed sides, and conspired as busily for the losing Jacobite cause. He wrote: 'History of the Revolution' (1706); 'Qualifications Requisite in a Minister of State' (1710); etc. See James Ferguson, 'Ferguson the Plotter' (1887), ibid. 'Two Scottish Soldiers' (1888).

Ferguson, Sir Samuel, Irish poet: b. Belfast, Ireland, 10 March 1810; d. Howth, Ireland, 9 Aug. 1886. In early life he was a prominent member of the Irish bar; in 1867 was appointed deputy keeper of the public records of Ireland; and in 1878 was knighted in recognition of his antiquarian and literary accomplishments. He will best be remembered as the author of the stirring poem, 'The Forging of the Anchor,' which first appeared in 'Blackwood's Magazine.' Chief among his other publications are: 'Lays of the Western Gael' (1864); 'Congal' (1872), a poem in five books; 'Poems' (1880); 'Shakespearean Brevities' (1882).

Fergusson, Arthur Walsh, American linguist: b. Benicia, Solano County, Cal., 4 Dec. 1859. He was graduated at St. Augustine College, Benicia, in 1877, and at the Georgetown University Law School in 1885. He first came into public notice in 1889 when made official interpreter of the American conference at Washington. Subsequently he was secretary of the International American Monetary Commission in 1891; official interpreter of the Intercontinental Railroad Commission in the same year; secretary of the United States Chilean Claims Commission in 1893; secretary of the United States and Venezuelan Claims Commission in 1894; chief translator of the Bureau of American Republics in 1897; official interpreter of the American and Spanish Peace Commission at Paris in 1898; and Spanish secretary of the United States Philippine Commission in 1900.

Fergusson, James, Scottish writer on architecture and archæological subjects: b. Ayr, Scotland, 22 Jan. 1808; d. London 9 Jan. 1886. He went to India as partner of an important commercial house, started an indigo factory on his own account, and after some years retired from business to devote himself to the study of architecture and early civilizations. In 1845 he published 'Illustrations of the Rock-cut Temples of India'; in 1849, 'A Historical Enquiry Into the True Principles of Beauty in Art'; in 1851, 'The Palaces of Nineveh and Persepolis Restored'; in 1855 'Illustrated Hand-book of Architecture'; in 1862, 'History of the Modern Styles of Architecture,' a sequel to the handbook, both being afterward combined in his 'History of Architecture in All Countries, From the Earliest Times to the Present Day' (1865-7), and completed by a 'History of Indian and Eastern Architecture' (1876). He also wrote 'Fire and Serpent Worship'; 'Rude Stone Monuments in All Countries.' He ranks among the foremost writers upon architecture.

Fergusson, Robert, Scottish poet: b. Edinburgh 17 Oct. 1750; d. 16 Oct. 1774. He became clerk in a law office, and wrote poems both in pure English and in the Scottish dialect, the latter being much superior to the former. His best productions display a rich fund of natural humor, keen powers of observation, and an excellent command of language. He was buried in the Canongate churchyard, Edinburgh, where Burns erected a monument to the memory of this kindred genius. His 'Poems' first appeared in 1773, and have been often reprinted

Fergusson, Sir **William,** English surgeon: b. Prestonpans, Scotland, 20 March, 1808; d. London 10 Feb. 1877; and educated at Edinburgh University. Sir William was one of the leading consulting surgeons in Europe, the author of 'A System of Practical Surgery,' and the inventor of numerous surgical instruments embodying ingenious improvements. He was created a baronet in 1865, "in consideration of distinguished merit and eminence as a surgeon."

Feriæ, fē'ri-ē, in ancient Rome, public holidays, during which all labor ceased, and all judicial and political proceedings were suspended. The feriæ were divided into two classes, general holidays and private holidays, observed by certain families or individuals. On these days the temples were visited, and prayers and sacrifices offered.

Feringhee, or **Feringee,** fe-ring'gē, the name given by the Hindus to the English and other Europeans. The word is intended to be disrespectful rather than complimentary.

Ferino, Pierre Marie Barthélemy, pē ār mä rē bar tāl mē fā rē'nō, Count of, French general: b. Caravaggio, Lombardy, 1747; d. Paris 28 June 1816. Having entered the Austrian army, he served in the Seven Years' war, but being unjustly treated by the Austrian government, went to France in 1789, and rose to prominence in the French army. The courage which he displayed at the defense of the bridge of Huningen procured for him the rank of grand-officer of the Legion of Honor (1804), as well as the title of senator. In 1808 he was made a count. Having voted for the deposition of Napoleon, Ferino received from Louis XVIII. the cross of St. Louis, as well as letters of naturalization, which in consequence of the separation of Lombardy from France had become necessary in order to entitle him to sit in the new chamber of peers. The name of this general is written on the east side of the triumphal *Arc de l'étoile.*

Fermanagh, fėr-man'ạ, an inland county, in the province of Ulster, Ireland; area, 714 square miles. The county is divided lengthwise into two nearly equal portions by Lough Erne. The principal towns are Enniskillen and Fermanagh. Its port is Ballyshannon. Pop. 65,300.

Fermat, Pierre de, pē ār de fār mä, French mathematician: b. Montauban 1601; d. Toulouse 12 Jan. 1665. He was engaged in his youth with his friend Pascal in very profound investigations as to figured numbers, on which he afterward founded his calculation of probabilities, of which he may be considered the inventor. He also devoted particular attention to the general theory of numbers, and made many important discoveries in regard to it, far outstripping any of his predecessors; he squared the parabola in a much simpler way than Archimedes had done, and contributed greatly to the progress of geometry. His method of finding the greatest and least ordinates of curve lines is closely analogous to the method of the differential calculus, then unknown. He carried on a keen controversy with Descartes, whose 'Geometry and Optics' were at variance with his 'Theoria de Maximis et Minimis.' Letters of his, written in 1636, prove that he was acquainted with the method of representing curves by equations before the publication of the 'Geometry' of Descartes, hence M. Libri has declared that he shares with Descartes the honor of having invented the mode of applying algebra to geometry. His collected works were published after his death, under the title of 'Varia Opera Mathematica' (1679).

Fermat's Last Theorem, the celebrated proposition that the equation $X^n + Y^n = Z^n$ cannot be satisfied by integral values of X, Y, and Z, and when n is an integer greater than 2. It was stated, though without proof, by the French mathematician Pierre de Fermat, about 250 years ago. Proofs have been found for many other remarkable theorems in the theory of numbers that were given by Fermat in the same manner, but this one has resisted all attempts at demonstration. There is no sufficient reason to believe it false, and it has indeed been proved to be true for every value of n from 3 up to about 97, and also for many special values greater than this; but no general proof, valid for all values of n, has yet been given. Many interesting things about the equation have been established, however. It is true for n, for example, if it is true for any factor of n; and this has led mathematicians to limit their study of it to the case in which n is a prime number. When n is prime, it is easy to show that the equation cannot be satisfied if any one of the three numbers X, Y, and Z is prime. It is also easy to show that when n is prime there is no solution unless $X + Y - Z$ is divisible by n. Many other similar properties are also known, but the general demonstration of the proposition does not appear to be possible by any of the methods with which mathematicians are now familiar.

Ferment Oils, in chemistry, volatile oils produced by the fermentation of various plants, not originally contained therein, and different from the oils which are extracted from the unfermented plants by distillation with water. They were known to the alchemists, and by them designated quintessences. Ferment oils are for the most part more soluble in water than ordinary volatile oils.

Fermentation (from Lat. *fermentare,* from *fervere,* to boil), a term whose meaning has undergone considerable changes at different times in consequence of the progress of chemistry and biology. By the alchemists it was often used to describe any reaction accompanied by boiling or effervescence, even when purely inorganic, but among older meanings that which comes nearest to its present signification has reference to its use to describe such familiar but mysterious processes as the transformation of grape-juice into wine, the formation of alcohol from the saccharine fluids prepared from cereals, and the raising of the dough in bread making. Closer examination has shown that these processes are only a few out of many of a similar kind, and now all such processes are included under the name fermentation. In its present sense it may be defined as including all chemical changes brought about through the agency, immediate or at least apparently immediate, of micro-organisms or of organic substances immediately derived from the vegetable or animal kingdom, these substances remaining essentially the same after the reaction as they were before it. The organism or substance which produces the fermentation is known as a *ferment,* and in accordance with the foregoing definition ferments may be divided into two main groups, namely, (1) organized or formed ferments, and (2) unorganized, unformed, or soluble ferments, usually called *enzymes.* Both kinds are nitrogenous organic bodies of somewhat unstable character, and in both cases the amount of ferment required to transform a given amount of the fermentable substance is relatively very small. The organized ferments are, however, living bodies of microscopic size belonging to the groups of fungi and bacteria, and are therefore capable of growth and reproduction, while the enzymes are lifeless substances of definite chemical composition. The action of the enzymes, accordingly, is often separated from that of the organized ferments and not included under the term fermentation, but the present state of our knowledge does not seem to offer sufficient warrant for such a course.

The enzymes or unorganized ferments play an important part in the vegetable and animal kingdoms. Thus, the solid, insoluble reserve materials stored up in the seeds, roots, underground stems, and other parts of plants are by their means transformed into soluble substances capable of being diffused throughout the plant-body. These enzymes are of protoplasmic origin, and are complex proteid compounds. The exact nature of their action is unknown, but all, or nearly all, produce their changes by a process known as *hydrolysis,* the nature of which may be best elucidated by citing a particular instance, the action of the enzyme *invertase* or *invertin* (see below) on cane-sugar. The molecule of cane-sugar under the influence of the ferment takes up a molecule of water, which becomes *fixed,* that is, incorporated with it, and then the combination resolves itself into the two simpler sugars, dextrose and levulose. The equation is as follows: $C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6$. The enzyme remains apparently unchanged, and a very small quantity of it seems capable of transforming an indefinite amount of the substance on which it acts. In one case, however, it has been proved that the enzyme forms a compound with the fermentable substance, and that the final products, including the enzyme, are then produced by the solution of this compound in water. This is probably the mode of action in all cases, and it is certainly much more intelligible than the former explanation by *catalytic* or contact action. The optimum temperature for most enzymes is between 85° and 120° F., and they are most active in the dark. The best-known enzyme is *diastase,* which is present in malted grain and converts starch into maltose and dextrin. Other enzymes are: *invertase,* already referred to; *cytase,* which acts chiefly on the cellulose of the cell-walls of grain and other seeds; *inulase,* which transforms inulin into levulose in various bulbs and tubers; *emulsin,* which decomposes the glucoside amygdalin of many rosaceous plants into glucose, benzoic aldehyde, and hydrocyanic acid; *pepsin,* found in gastric juice; *trypsin,* secreted by the pancreas; *zymase,* to which the alcoholic fermentation has been ascribed; and *urase,* to which the fermentation of urea into ammonium carbonate is primarily due.

The organized ferments, or micro-organisms concerned in fermentation, all belong to the group of cryptogamic plants known as Fungi, and their near allies the Bacteria. The most highly organized members of this group concerned in fermentation are some of the molds, but their part in fermentation is of little importance, and we need not further consider them. We may therefore discuss the micro-organisms of fermentation under the two heads: (1) Saccharomycetes, or Yeast-Fungi, and (2) Schizomycetes, or Bacteria. The Saccharomycetes are minute unicellular plants of an oval shape, surrounded by a cell-wall and containing granular protoplasm in which several vacuoles are conspicuous. They reproduce themselves by gemmation or budding, and by this means chains of cells closely resembling the hyphæ of a mycelium are formed; but very few species develop any true mycelium, such as we find in the molds and other fungi. The Bacteria, Schizomycetes, or Fission-Fungi, are a very important group of microscopic cryptogams usually classed with the fungi. Their importance arises not only from the part they play in fermentations, but also from their widespread activity in the order of nature, and especially from their action in producing numerous zymotic diseases in man and other animals. See Bacteria.

The yeast-fungi cannot assimilate free nitrogen, but they can extract it from salts of ammonia and from various organic bodies. They can take up carbon from sugars, glycerin, tartaric acid, citric acid, acetic acid, ethyl alcohol, benzoic acid, phenol, and other organic bodies; but they can obtain their nutriment only in the presence of such substances as potash, lime, and phosphoric acid. Unlike nearly all the bacteria, the yeasts can live in acid media if the acid be not present in excessive quantity. The presence of free oxygen is very favorable to the growth of yeast-fungi, but under these conditions the transformation of sugar into alcohol greatly diminishes in vigor. If, however, free oxygen be excluded, fermentation proceeds vigorously. The optimum temperature for the growth of yeast-fungi is from 77° to 86° F., and they seem to be quite indifferent to light and electricity. Bacteria assimilate nitrogen most readily from peptone, but many other substances can also yield. Carbon is most readily taken up from sugars, glycerin, tartrates, citrates, lactates, acetates, etc. Most bacteria are unfavorably influenced by light, and in respect to temperature there is a great diversity among the different species, some flourishing at 60° to 70° C. and others at freezing point, but for several of the best-known species the optimum temperature is 25° to 35° C. The *obligate aërobic* forms cannot live in the absence of free oxygen, while the *obligate anaërobic* kinds are destroyed by the smallest trace of free oxygen. Between these two extremes we have *facultative aërobic* species, which are generally anaërobic, but can tolerate some free oxygen, and *facultative anaërobic* species, generally aërobic but able to live when the free oxygen is much diminished. Phosphoric acid, potash, lime, and similar bodies are necessary to their growth.

The most important of all fermentations due to Saccharomycetes is that by which alcohol is obtained from sugar (the sugar itself being largely that derived from the starch of barley or other cereal), and it is in connection with this process that the subject has been most thoroughly studied. The species of fungus or yeast used in this process is known as *Saccharomyces cerevisiæ*, but of this two kinds are distinguished, namely, *top yeast and bottom yeast.* The former is used in top fermentation, which is carried on at a rather high temperature (60° to 85° F.) and is rather violent, carbon dioxid being freely evolved and carrying the yeast to the surface. Bottom yeast is used in the slower bottom fermentation at about 40° to 50° F., in which carbon dioxid is more gently evolved and the yeast therefore remains at the bottom. Bottom fermentation is chiefly used in the manufacture of lager beer. The sugars directly fermentable by this process are those with the formula $C_6H_{12}O_6$, namely, dextrose, levulose, and galactose. Cane-sugar ($C_{12}H_{22}O_{11}$) is first changed by an enzyme *invertase* (see above) contained in the yeast into dextrose and levulose, which are then fermented. The chief products of the fermentation are alcohol and carbon dioxid, but other bodies, such as glycerin, succinic acid, propyl, amyl, and other higher alcohols, are also produced. The process of fermentation continues until the alcohol forms about 14 per cent of the solution, when the yeast-plant cannot continue its action any longer.

Many theories of alcoholic fermentation have been advanced. Lavoisier, treating sugar as an oxid, thought that it was chemically resolved by fermentation into two other oxids, carbon dioxid and alcohol. When the organic nature of yeast was proved beyond doubt, the physiological theory was advanced, according to which the sugar is the food of the plant and the products of fermentation are its excretions. The celebrated chemist Liebig, however, contended that fermentation was a purely chemical process, and his later opinion has been in part reverted to by more recent observers. Pasteur proved conclusively that fermentation was bound up with the life of the organisms, but in what manner is still uncertain. Traube regarded the cells as centres for the production of enzymes, thus reducing fermentation by organized ferments to that produced by unorganized ferments. Traube's theory has gained considerable ground lately on account of the successful extraction from yeast by Buchner of an enzyme, *zymase*, which can produce all the phenomena of alcoholic fermentation.

The chief micro-organism of the vinous fermentation is *S. ellipsoïdeus*. The elliptical cells of this species are found on the grapes and in the air of grape-growing districts, and fermentation is thus set up spontaneously without the actual addition of yeast. Recently pure cultures of the wine-yeast have been prepared and used with very good results in the fermentation of grape-juice. E. C. Hansen, an able Danish investigator, has added greatly to our knowledge of the chief yeast-fungi, and has prepared and thoroughly examined several pure cultures of the three most important species, *S. cerevisiæ*, *S. pastorianus*, and *S. ellipsoïdeus*. He has described six kinds in all, two belonging to the last species, three to the second, and the sixth to the first, the distinctions being founded on the temperature of spore-formation and the conditions under which a surface film forms in a liquid medium. Hansen has also cultivated two pure forms of brewers' yeast, known as Carlsberg No. 1 and No. 2. Both are bottom yeasts, but the beer produced by No. 1 has less carbon dioxid than that of No. 2, and is used chiefly for bottling, the No. 2 beer being preferred for export.

Of the fermentations set up by bacteria only some of the most important can be referred to here. (1) *Acetic Acid Fermentation.* In this fermentation alcohol becomes oxidized into acetic acid, the total reaction being representable by the equation:

$$C_2H_5OH + O_2 = C_2H_4O_2 + H_2O.$$

The microbe concerned in the fermentation, if allowed to continue its action, will oxidize the acetic acid into carbon dioxid and water. Two bacilli, namely, *Bacillus aceti* and *B. pasteurianus*, have been described as taking part in this important fermentation, which is the basis of the commercial manufacture of vinegar from wine. (2) *Lactic Fermentation.* The souring of milk which has stood for some time is due to this fermentation, by which the milk-sugar becomes transformed into lactic acid through the agency of bacteria. Carbon dioxid is an invariable product of the fermentation. (3) *Butyric Fermentation*, often set up in milk which has undergone the lactic fermentation. (4) *Nitrification of Ammonia*, a process of vital importance in nature, by which organic nitrogen becomes fixed in soils as nitrates and nitrites. The process of decay and putrefaction, with the production of *ptomaïnes*, also belong to this section of the subject of fermentation.

(See ALCOHOL; BREWING; DISTILLED LIQUORS; VINEGAR; WINE; etc.) Among treatises on the subject the following may be mentioned: A. Jörgenson, 'Die Mikroorganismen der Gärungsindustrie,' translated into English by H. T. Brown as 'The Micro-organisms of Fermentation'; Schützenberger, 'Fermentation'; Trouessart, 'Microbes, Ferments, and Moulds.'

Fermented Liquors. See DISTILLED LIQUORS.

Ferments, agents in causing fermentation; these may be either organized or unorganized. The former belong to microscopic fungi of the lowest order. The latter are sometimes called chemical ferments, as they bring about chemical changes in other substances, with which they are brought in contact, without themselves undergoing a permanent transmutation.

Fermo, fĕr'mō (ancient FIRMUM PICENUM), Italy, city in the province of Ascoli Piceno, 32 miles south-southeast of Ancona. It was founded by the Sabines before Rome existed; and has remains of old walls. It gives name to an archiepiscopal see, and has a cathedral, several other churches, a town-house, part of which dates from the 14th century; collections of statuary and paintings. Its harbor is situated on the Adriatic, about three miles distant. Pop. 15,000; of the commune, 20,542.

Fermor, Henrietta Louisa, COUNTESS OF POMFRET, English writer: d. 15 Dec. 1761. Her letters were published in 'Correspondence between Frances, Countess of Hartford (afterward Duchess of Somerset), and Henrietta Louisa, Countess of Pomfret, between . . . 1738 and 1741' (1805).

Fermoy, fĕr-moi', Ireland, town, in the county of Cork, 22 miles north-northeast of the city of Cork, on the Blackwater. On the river opposite to the town are infantry, artillery, and cavalry barracks, accommodating about 3,000 men. There are here Fermoy College, St. Coleman's Roman Catholic College, two convents, and a handsome Roman Catholic cathedral. It has some large flour-mills and a brewery. Pop. 6,469.

Fern, Fanny. See PARTON, SARA PAYSON WILLIS.

Fern, Male (*Dryopteris filix-mas*), a native fern of the northern part of the United States and of Europe, Asia, Africa and South America. In medicine the rhizome is used. It contains an active oleoresin, the most important constituent of which is filicic acid, and is a very efficient remedy for the treatment of tapeworm, particularly of the genus *Tænia*. Other American species of the same genus, *D. marginale, D. goldianum*, contain small amounts of the same oleoresin as that found in male fern, and can be used for much the same purposes.

Fern-owl, the common British nightjar (*Caprimulgus europæus*), which goes by many other provincial names, as "goat-owl" and "churn-owl," due to the noises it makes and an erroneous supposition that it is a kind of owl. Consult White's 'Selborne'; and see NIGHTJAR.

Fer'nald, Charles Henry, American zoologist: b. Mount Desert, Maine, 16 March 1838. He was an acting ensign in the United States navy during the Civil War; and professor of natural history at the Maine State College in 1871-86. In the latter year he was appointed professor of zoology at the Massachusetts Agricultural College. His publications include: 'Tortricidæ of North America'; 'The Crambidæ of North America'; 'The Pterophoridæ of North America'; 'Pyralidæ of North America'; etc.

Fernald, Chester Bailey, American writer: b. Boston, Mass., 18 March 1869. He is author of: 'The Cat and the Cherub, and Other Stories' (1896); 'Chinatown Stories' (1899); 'The Moonlight Blossom' (1899), a drama; etc.

Fernald, James Champlain, American Baptist clergyman and author: b. Portland, Maine, 18 Aug. 1838. He was graduated at Harvard 1860, and at Newton Theological Seminary 1863, and was ordained to that ministry 1864. He settled in Ohio, holding pastorates in Granville and Springfield; removing to New York in 1889. He has since done much editing and writing, having been editor of 'Synonyms,' 'Antonyms,' and 'Prepositions in the Standard Dictionary' and editor-in-chief of the 'Student's Standard Dictionary,' and of the 'Homilitic Review.' Among his works are: 'The Economies of Prohibition'; 'The New Womanhood'; 'Synonyms, Antonyms, and Prepositions of the English Language'; 'The Spaniard in History' (1898); 'The Imperial Republic' (1898); 'Training of Children' (1898); 'True Motherhood' (1900).

Fernandez, Juan, hoo än' fĕr nän'deth, Spanish navigator and explorer: b. probably Cartagena, Spain, 1536; d. Ligna, Chile, 1602. In sailing between the ports of South America he stood out to sea, benefiting by the trade winds and thus shortening the time of the voyage, for which he narrowly escaped condemnation as a sorcerer. He discovered the island which was named after him 1563, and tried to establish a colony there, but failed in this enterprise. He also discovered the islands of St. Felix and St. Ambrose 1574. The sojourn of Alexander Selkirk upon the island of Juan Fernandez probably suggested 'Robinson Crusoe' to Defoe.

Fernandez, Leandro, Mexican statesman: b. in the state of Durango, 27 Feb. 1851. He was educated at the Juarez Institute at Durango and the School of Engineers, Mexico City, adopting engineering as his profession. Was given the title of 'assayer' in 1873 and 'engineer' in 1876. Was 'official mayor' of the department of communications for 19 months, then successively director of the government mint at Mexico City six and a half years; governor of Durango one year; and secretary of Fomento more than two years. He has also been director of the National Astronomical Observatory and professor in and director of the National School of Engineers, Mexico City. He was appointed secretary of communications and public works in 1904.

Fernandez de Cordova, Diego, dē-ā'gō fĕr-nän'deth dā kor'dō-vä, marquis of Guadalcazar, Spanish statesman: b. Cordova about 1580; d. after 1629. He was made viceroy of Mexico in 1612, holding the office till 1621. He founded the cities of Lerma, Cordova, and Guadalcazar, completed the Mexican aqueduct and was viceroy of Peru from 1622-29.

Fernandez de la Cueva, Francisco, frän-sĭs'cō fĕr-nän'deth dā lä kwā'vä, duke of Albuquerque, Spanish statesman: b. about 1610. He was appointed viceroy of Mexico 1653, holding the office until May 1661. During his term the city of Mexico was greatly developed and the cathedral constructed. His later years were spent as viceroy of Sicily.

Fernandez y Gonzalez, Manuel, mä-noo-äl' fĕr-nän deth ē gōn thä leth, Spanish poet and novelist: b. Seville, Spain, 1830; d. Madrid 6 Jan. 1888. A boyhood in Granada and seven years' army service afforded him varied experience of life and men. From 1846 he gave himself to literature; and the plays, 'Struggling Against Fate' (1848); 'The Cid' (1858); 'A Duel on Time' (1859); 'Imperial Adventures' (1864), well constructed and full of humor, won great popularity. Among his novels are: 'The Seven Children of Lara' (1862); 'The Bloody Queen' (1883); 'The Plantagenet Brothers' (1889). A volume of his poems appeared in 1858.

Fernandez-Lizardi, José Joaquin, hō-sā' hōä-kēn' fĕr-nän'deth-lē-thär'dē, Mexican novelist: b. City of Mexico 1771; d. there June 1827. His most famous work is 'Periquillo Sarniento' (1816, new ed. 1884). He also published two novels, 'Sad Nights and Gala Days' (1823), and 'Life and Exploits of the Famous Knight Don Catrin de la Facheuda' (1832).

Fernandez Madrid, Jose, hō-sā' mä-thrēth fĕr-nän'deth, Colombian poet and statesman: b. Cartagena, Colombia, 9 Feb. 1789; d. near London, England, 28 June 1830. He was for a short time president of his country in 1816, but was afterward exiled to Cuba where for nine years he was prominent as a physician. In 1825 he was sent by Bolivar as minister to England. He published a volume of poems: 'The Roses' (1822); also two tragedies, 'Atala' (1822), and 'Guatimozin' (1827).

Fernandez Navarrete. See NAVARRETE, JUAN FERNANDEZ.

Fernández, de Palencia, Diego, dē-ā'gō dā pä-lĕn'thē-ä fĕr-nän'deth, Spanish-American historian: b. Palencia, Spain, about 1530; d. Seville 1581. He was apparently a soldier of fortune, lured to the scene of Pizarro's great conquest in the hope of fabulous wealth. He had some fighting experiences, and wrote: 'The First and Second Parts of the History of Peru' (1571), a narrative of the subjugation of the Incas.

Fernandez de los Rios, Angel, än-hāl' fĕr-nän'deth dā lōs rē'ōs, Spanish writer: b. Madrid, Spain, 27 July 1821; d. 1879. Active in politics and political journalism at home, he was banished, and became a man of letters in Paris. He wrote: 'All or Nothing' (1876), an anti-Bourbon prose study of social conditions: 'A Week in Lisbon' (1876); and many essays of value on the politics and resources of the Peninsula.

Fernandina, fĕr-nan-dē'na, Florida, city, port of entry, and county-seat of Nassau County, on Amelia Island, Amelia River, and the Florida C. & P. R.R.; 33 miles north by northwest of Jacksonville. Its manufactures are lumber, canned oysters, plastering fibre (made from palmetto), and cotton goods. It exports cotton, phosphates, lumber, plastering fibre, and canned goods. It is a favorite winter resort. A shell road leads to Amelia Beach, and nearby is Cumberland Island, the home of Gen. Nathaniel Greene (q.v.). Pop. (1900) 3,245.

Fernando de Noronha, fĕr-nän'dō dā nō-rōn'yä, an island, of volcanic origin, in the South Atlantic, belonging to Brazil; area, about 12 square miles. It has a rugged, mountainous, wooded surface. It is used as a penal settlement for Brazilian male criminals.

Fernando Po, fĕr nan' pō (Span. fĕr nän'dō pō'), an island belonging to Spain, in the Bight of Biafra, 20 miles from the West African coast. It is of volcanic origin, about 40 miles in length by 20 miles in breadth. It is mountainous and covered with dense forests of valuable timber, while the land gradually rises from the steep and rocky coasts into two peaks culminating upward of 10,000 feet above sea-level. It is well-watered, and sugarcane grows in abundance. Yams form the staple food; birds and fish are plentiful. The climate is very unhealthy. The capital is Clarence Cove. This island was discovered in 1471 by the Portuguese, who ceded it to Spain in 1778. The Spaniards eventually abandoned it, and the British, in 1824, selected it as a suitable military depot and naval station. They, in their turn, abandoned it in 1834, on account of its unhealthfulness. The Spaniards again took possession in 1844. It is now used by them as a penal settlement, to which, in 1869, several Cuban patriots were deported, as political prisoners.

Ferne Islands. See FARNE ISLANDS.

Ferney, or **Fernex,** fār-nā, France, town in the department of Ain, about five miles north of Geneva. It is small, and its only manufactures are watches and pottery. It is chiefly noted for having been the chief residence of Voltaire (who in fact founded it) from about 1760 to 1778. The house in which he lived is still standing, and the church, with the inscription, '*Deo erexit Voltaire,*' is now a farmhouse. Pop. 1,189.

Fernkorn, Anton Dominikus, än'tōn dō-mi-ni-koos' fĕrn'korn, Austrian sculptor: b. Erfurt, Saxony, 17 March 1813; d. Irrsin, near Vienna, 16 Nov. 1878. He studied under Stiglmayer and Schwanthaler 1836–40, and attracted attention by his first group, 'St. George and the Dragon,' the Austrian government then appointing him director of the Imperial bronze foundry at Vienna, where he executed his masterpiece, a colossal statue of Archduke Karl 1860, and his statue of Prince Eugéne 1865. Among his other works are a colossal bust of Radetsky; a marble statue of the poet Frederick Heffel, and a monument of Ressil.

Fer'now, Bernhard Eduard, American scientist: b. Inowraclaw, Germany, 7 Jan. 1851. He was educated at the University of Königsberg; removed to the United States in 1876 and engaged in metallurgical work; and was chief of the division of forestry in the United States Department of Agriculture in 1886–98. In the latter year he was made director and dean of the New York State College of Forestry at Cornell University. He is the author of 'The White Pine' (1899); 'Report Upon Forestry Investigations of the United States Department of Agriculture 1877–98' (1899); etc.

Fernow, Berthold, American author: b. Inowraclaw, Germany, 28 Nov. 1837. He entered the Prussian army and became lieutenant in 1860. He soon after removed to the United States; became a private in the 4th Missouri Cavalry in 1862; and was promoted lieutenant of the 3d United States Colored Infantry in 1863. He was archivist of New York State in 1876-89. He has written 'Albany and Its Place in the History of the United States' (1886); 'Ohio Valley in Colonial Days' (1889); etc., and edited 'Documents Relating to Colonial History of New York' (Vols. XII., XIII., XIV.); 'New York in the Revolution' (1887); and 'Records of New Amsterdam' (1897).

Ferns and Fern-allies. The ferns are representatives of an extensive branch of the plant world technically known as *pteridophytes,* standing between the mosses and hepatics (*bryophytes*) on the one hand and the cycads and conifers (*gymnosperms*) on the other, at the head of the now obsolete subdivision of plants known as cryptogams. They resemble the former groups so closely in their method of sexual reproduction and in showing alternating phases of growth that both mosses and ferns are often united under a single primary division of plants as *archegoniates,* so called from the common possession of a structure described below as the archegone. The ferns differ from the mosses in their highly developed vascular or woody system seen in the fibrous strands of the leaf-stalks and the veins of the leaves, and so are still sometimes called vascular cryptogams. Besides the ferns, popularly so known, there are various groups of plants closely allied to ferns which with them make up the branch pteridophytes. Among these fern-allies are the running-pine or ground-pine, familiar in its use for Christmas decoration, the selaginellas frequent in cultivation, the field horsetail, and the scouring-rush. These will be treated in their proper sequence below.

The mature fern-plant, which may stand as a representative pteridophyte, consists of a woody axis bearing scattered or clustered leaves according as this axis is a creeping structure or an upright trunk. In our northern species this axis is either below the surface of the ground or just at the surface, but in some of the species of tropical regions it often forms a trunk from one foot to fifty feet in height, or even more, bearing its leaves at the summit and forming a tree-fern.

On the under surface of certain leaves of ordinary ferns little clusters of stalked bodies (*sporangia*) appear, which are variously arranged in different species, in rounded or linear masses (*sori*) or in a few species are scattered over the surface of the leaf. These structures consist of a membranous wall enclosing minute bodies — the fern-spores. These are the reproductive bodies of the fern asexually produced by repeated division of the interior portion of the young sporangium, and are often popularly known as "fern-seeds." This is a misnomer, for they rather find their homology with the pollen-grains and young embryo-sacs of the higher plants. In the sporangia of some ferns a series of peculiar cells serves the purpose of rupturing the sporangium wall, and by an elastic movement scatters the spores at some distance from the plant producing them. Either at once or after a period of rest the fern-spore sprouts and produces a green hepatic-like structure known as a prothallus. This is a flat expanse of soft green tissue, usually more or less heart-shaped, and ranging up to a half inch or more in diameter. It forms root-hairs beneath, and grows exactly like an ordinary new plant. On its under surface among the root-hairs two sorts of structures are produced: (1) A series of rounded bodies known as antherids, in which minute motile cells are formed known as antherozoids, these being the male or sperm cells connected with the sexual reproduction of the fern; (2) a series of flask-shaped bodies (archegones) more deeply imbedded in the tissues of the prothallus, which contain a single specialized cell at the bottom of the flask, known as the egg, this being the female reproductive cell. The sperm-cells escaping from the antherid swim in the delicate film of moisture which may bathe the surface of the prothallus, swarm about the mouth of the archegone, and one of them enters the neck of the flask-like structure, penetrating the mucilaginous contents of its tube, and fuses with the egg, thus effecting a true sexual reproduction. The fertilized egg soon commences division, increases in size, and develops a primary root and leaf, ultimately growing into a new fern-plant. The two alternating phases of growth in the life period of the fern are thus strongly marked; the sexual phase (prothallus) is often known as the gametophyte, and the asexual phase (the fern-plant) which follows is known as the sporophyte or spore-producing phase.

In some of the fern-allies like *Marsilea* and *Selaginella* the plants produce two kinds of spores, (1) microspores, which develop into prothalli producing only antherids, and (2) macrospores, which develop into prothalli producing only archegones. In these plants, particularly *Selaginella*, the prothallus is much reduced in size, and the sexual reproduction approaches that of the pines and other conifers, except that it takes place away from the plant producing the spores. The microspores of *Selaginella* are thus the exact counterparts of the pollen-grains of the pine, and the macrospores correspond to what is known as the embryo-sac in the young pine-cone, to that part of the ovule in which the egg-apparatus appears, and in which the seed is ultimately developed.

Ferns are distributed all over the world but diminish in the number of species, in the profusion of individuals, and in the relative proportion to the total vegetation of the locality as we pass from tropical to polar regions. Moist insular climates are best adapted to their development. Java has 575 species of ferns, while New York State with about the same area has scarcely one tenth as many. Jamaica, with about the area of Connecticut, has nearly 500 species; Hawaii, Samoa, New Zealand, and the Philippines are other prolific regions. While moist conditions favor fern-growth and development, certain species have adapted themselves to dry climates and grow on open exposed rocks of semi-arid regions. Such ferns are provided with woolly hairs, tangled scales, waxy powder, or other mechanical contrivances to conserve their moisture. One species of the so-called "resurrection-plants" (*Selaginella lepidophylla*) of the arid regions of the southwest conserves its moisture during the dry season by coiling its branches inward so as to form a compact ball. On the return of moisture it flattens out and exposes its fresh green surface. The "resurrection-fern" curls up in a similar way, its under surface being protected by a layer of scales. It grows on trees in the southern States and the West Indies.

The ferns of temperate regions are terrestrial in their habit, but as we approach the tropics a large number become epiphytic, growing with mosses and orchids on the trunks and branches of trees. The filmy ferns frequently cover the trunks of tree-ferns completely.

There are over 5,000 described species of pteridophytes in the present flora of the world, which are grouped according to their characters under seven distinct orders. Of these we have nearly 290 species within the limits of the United States.

Geologically, the pteridophytes are a very old group dating back to the Devonian and reaching their first culmination during the Carboniferous Age, in which they formed the bulk of the vegetation of the coal-measures. Besides ferns, some of the fern-allies of those times attained very great size, as shown in the giant trunks of *Lepidodendron* and *Sigillaria*, related to the modern club-mosses, and in the large stems of *Calamites*, related to our present diminutive scouring-rushes. The various types of the modern pteridophytes and their distinctive characteristics will be treated under their respective orders, arranged, as nearly as a lineal series can show it, in their relative rank in the scale of vegetable life.

I. *Ophioglossales.*— The adder-tongues and grape-ferns are eusporangiate; that is, their sporangia develop from the interior tissues. They include plants of a fleshy texture, bearing their thick-walled sporangia in spikes or panicles. The prothallus, so far as known, is subterranean and colorless. We have in the United States seven species of adder-tongue (*Ophioglossum*), and 17 species of grape-ferns (*Botrychium*), the former having the sporangia in spikes and the latter having them in panicles. All our northern species are terrestrial plants with fleshy roots. *Cheiroglossa palmata* of Florida and the West Indies is a hanging epiphyte growing on palmetto-trunks and on other trees, and the curious strap-like *Ophioderma* of Hawaii and other Pacific isles grows in similar situations, with its pendant leaf from two to five feet long. The order *Ophioglossales* represents the simplest type of fern-growth in existence, and probably the oldest type as well. The species (about 60) are not numerous, but are very widely distributed.

II. *Marattiales.*— This order includes only tropical ferns of a coarse habit, ranging from two feet to ten feet in height. They are eusporangiate like the last order, but have the coiled-bud form of the true ferns. They also bear their sporangia dorsally, that is, on the under surface of the leaf, but these are formed in special boat-like receptacles known as synangia. *Marattia* and *Danæa* are the two principal genera. Two species of the former and nine of the latter are found in the North American tropics. The order is a smaller one than the last and, like it, consists of a single family.

III. *Filicales.*— The ferns proper, including nearly 4,000 species, are divided unequally among the eight families of this order. They are leptosporangiate (that is, the sporangia develop from the epidermal tissues), and all produce green prothalli of the type described above. Except the *Matoniaceæ*, a small family of two species, all are represented in America. Two families are tropical only, while the remaining five are also represented in the United States.

1. The flowering ferns, so called because the sporangia are panicled, are among the conspicuous features of our northern swamp vegetation in spring and early summer. The cinnamon-fern grows in great crowns, sending up its spore-producing leaves, which have a rich cinnamon color, a short time in advance of its rich crown of foliage-leaves. The royal flowering-fern grows in similar locations, but is larger, has more compound foliage, and bears its panicle at the summit of the foliage-leaf. The flowering ferns (*Osmunda*), with two genera from New Zealand and Africa, make up the family *Osmundaceæ* with 16 species. In this family the ring of the sporangia is rudimentary and the sporangia open longitudinally.

2. The Hartford fern or climbing fern (*Lygodium*) is the type of a second small family. Our species is low-growing, only two or three feet high, and twines closely about other vegetation. It is quite local, but where it grows it sometimes forms tangles. In Connecticut it is so rare that it is protected by law. The tropical species of this genus often climb trees for 40 feet or more. Another member of the same family is the curious curly-grass (*Schizæa*) of the pine-barrens of New Jersey. It is wholly unlike ordinary ferns, the foliage-leaves resembling curled grass-leaves and the spore-bearing leaf resembling a small sedge. The entire plant is only four or five inches high. These two species with two subtropical species of *Ornithopteris* form our four representatives of the family *Schizæaceæ*, whose 80 species are largely South American, though several species occur in the Old World. They are characterized by their pear-shaped sporangia with an apical ring. The sporangia are usually borne in spikes or panicles.

3. The *Gleicheniaceæ* are found in the tropics of both hemispheres, several species of *Dicranopteris* occurring in the uplands of the West Indies, forming almost impassable tangles or thickets. These ferns, instead of uncoiling at once, produce buds in the axils of the forked branches, and as the lower portions mature these buds develop successive upper growths. The tangles thus formed are often sufficient to bear the weight of a man, and it is possible to walk for some distance on these thickets.

4. The floating-fern (*Ceratopteris*), found rarely in Florida and Louisiana, and occasionally throughout the tropics of both hemispheres, is almost the only aquatic representative of the order. Its sterile leaves float on the surface of shallow waters, and its pad-like fertile ones project above the surface. The name *Ceratopteris* is derived from this fertile leaf, which branches like a deer's horn, and gives the name to the family *Ceratopteridaceæ*.

5. The tree-ferns of both hemispheres form a separate family *Cyatheaceæ*, though several members of this family are very diminutive, and ferns with trunks occur occasionally in other families. No tree-ferns occur in the United States, but 30 species or more are found in the higher altitudes of the West Indies, and many more occur in other tropical regions. In some portions of the mountains of Jamaica tree-ferns form half or three fifths of the forest vegetation, the trunks ranging from 6 to 50 feet in height. A well-developed tree-fern forms one of the most beautiful types of vegetation, rivaling the palms in grace and perfection of form. Some 200 species have been described, belonging chiefly to the genera *Cyathea, Alsophila, Hemitelia, Dicksonia*, and *Cibotium*.

6. The great mass of our ferns belong to the family *Polypodiaceæ*, often known as the true ferns, perhaps for no better reason than that they were the first to be called by the name of ferns. The members of this family have definitely stalked sporangia, always provided with an elastic vertical ring which causes the sporangium to burst transversely and thus disperses the spores. In some species, like the stag-horn fern, the sporangia are spread over the under-leaf surface in a uniform layer; in others, like the spleenworts and bird's-nest fern, they are in definite lines; while in our common polypody, the maidenhair, and the wood ferns they are in small rounded masses (sori). In some species the sorus is naked, but in most it is covered by a small membrane (indusium), primarily for the purpose of protecting the young sporangia. In some ferns, like the spleenworts, the indusium develops along a vein; in others, like the Christmas-fern, it is attached at one point and covers the sorus like an umbrella; in still others, like the maidenhair, it is formed of a modified portion of the margin of the leaf folded under so as to cover the young sporangium. The nature and position of the indusial covering forms one of the leading characters for the separation of genera under the Hookerian scheme of classification, while the Preslian scheme lays stress on the character of the venation, the fundamental branching of the fibro-vascular system of the plant. A more rational and natural scheme combines with these the habital and biological characters that serve to group in each genus ferns that really have a natural relation to one another.

In so large a group of plants as that presented by this family we must expect to find the greatest diversity of size and structure, dependent on the geographical distribution, the altitudinal distribution, and on the ecological conditions under which the various members of the family have become developed. Marsh, swamp, rocky hillside, cliff and moist ravine each have their characteristic species in every country, while the trees of every tropical region support an extensive epiphytic series which varies with every considerable change of altitude. Even exposed cliffs in semi-arid regions support their own peculiar ferns, which have become adapted to conditions that at first would appear wholly unsuited to fern-growth. Obviously only a few of the more common species which grow wild or in cultivation can be mentioned here.

The sword-fern (*Nephrolepis*), some forms of which are known in cultivation as the "Boston Fern," is a native of tropical America, occurring frequently in peninsular Florida. In its native haunts it is more commonly found on the trunks of palm-trees, though it often grows on the ground or on rotten wood. It is a favorite in cultivation, either in hanging baskets or in jardinières, and requires a rich soil and moist surroundings to thrive best. The sori are provided with a kidney-shaped indusium.

The maidenhairs (*Adiantum*) are perhaps the most graceful of the herbaceous ferns. Over 60 species are known, many of which have long been in cultivation. The luxuriant split-leaved *A. Farleyense* and the numerous fine-leaved varieties of *A. cuneatum and A. gracillimum* are among the most graceful in cultivation. Owing to their readiness to wilt most maidenhairs thrive best in Wardian cases.

In late years Japanese fern-balls have become popular in cultivation, consisting of the slender rootstocks of a species of *Davallia* wrapped about a mass of peat-enclosed soil, and held in form by wires. The Davallias are graceful ferns mostly confined to the Old World, though related genera are found in the American tropics. Numerous species are found in cultivation in the larger conservatories. Among our wild species the ostrich-fern (*Matteuccia*) is one of the best for out-of-door cultivation, to which it readily yields. It grows in graceful crowns from an erect rootstock, and has a bright green color. Its spore-bearing leaves are curiously rolled together so as to have the appearance of pods containing the copious sporangia. It requires a moist soil for its growth, and when growing wild thrives best in low ground. Other ferns suited for bed-cultivation are the graceful wood-ferns (*Dryopteris spinulosa*, and related species) and the Christmas-fern (*Polystichum*), both with dark foliage and crown-like habit, and the hay-fern (*Dennstædtia*) with a foliage of lighter green and a more scattered habit of growth resulting from its creeping rootstocks. The wood-ferns and Christmas-fern are firm in texture, and remain green throughout the winter; the hay-fern dies down with the early frosts. Another delicate pale-green species suitable for cultivation is the New York fern (*Dryopteris Noveboracensis*), which, however, has a range from New England to Alabama.

For rockeries the bladder-fern (*Filix fragilis*), the smaller spleenworts (*Asplenium trichomanes* and *A. platyneuron*), the rock-brake (*Pellæa*), and the curious walking-leaf are common among the best native species; and all thrive best if the rocks are part limestone. The last-named fern has a peculiar habit among our native species, shared, however, by many exotic ferns. The leaf, which is simple and tapers to a slender point from a rounded lobed base, takes root at the apex and forms a new plant, whose leaves may again take root and form still other plants. This peculiarity of taking steps away from the mother plant has given the name walking-leaf to this small fern, whose leaves range from 4 to 10 inches in length.

Aside from decorative value, ferns have little utility. The matted tufts of soft hair-like scales of some of the Hawaiian tree-ferns (*Cibotium*) are collected in commercial quantities and used for filling mattresses under the name "pulu." The male-fern (*Dryopteris filix-mas*) and some of its near allies are used in medicine as a vermifuge, and the soft parts of certain species are used for food. The mission of the fern, however, seems to be an æsthetic one, to minister grace and beautify the duller and more prosaic sides of nature.

7. In point of grace and delicacy none of the ferns as ordinarily known can equal the filmies, which flourish best at the higher elevations of tropical lands. These ferns differ from the true ferns not only in the form of the sporangium, and its attachment to a thread-like receptacle, but also in the texture of the leaf, whose blade is often only a single cell thick, so that the leaf is strongly translucent. Add to this delicacy of texture the most exquisite fineness of cutting and pattern, and place the leaves dripping with diamond dew-drops in masses on trunks of tree-ferns in the midst of a tropical luxuriance, and you have perhaps the nearest approach to a fern-paradise that could be imagined by the most ardent lover of nature. Such a picture can be found in the mountains of Jamaica and in many other tropical islands. The filmy ferns belong chiefly to the genera *Trichomanes* and *Hymenophyllum*, and although many are apparently so simple, the *Hymenophyllaceæ* form one of the most highly differentiated families among the ferns. A few others simulate them in texture, like the delicate New Zealand species of *Leptopteris* and some species of *Asplenium* in the American tropics, but these are representatives of two distinct families. The genus *Loxsoma* represents a structural connecting-link between the genus *Davallia* and the filmy ferns, and this is apparently their only point of kinship. Two species of *Trichomanes* occur under moist rocks in some of our Gulf States, one of them scarcely over a half inch in height.

IV. *Salviniales.*— Next to the ferns are the members of this order, in which spores of two sorts are produced in special conceptacles resembling small pods or spheres. There are two types of habit represented, one series (*Salviniaceæ*) floating on the surface of water, and the other (*Marsileaceæ*) rooting in mud. *Salvinia*, with oval leaves, is occasionally seen in cultivation but is rare in a wild state. *Azolla* is found in great abundance in Florida, sometimes covering the surface of ponds with its delicate branching small-leaved stems. A second species occurs in California. *Marsilea* is the type of the second family, and has a four-parted leaf resembling that of *Oxalis*. It grows on the wet borders of ponds, or if the water becomes high, it elongates its leaf-stalks and the leaves float on the surface like four-leaf clovers. Its conceptacles are oval and are borne on short stalks. One species grows abundantly at Bantam Lake, Connecticut, and others in Florida and in the far Northwest, where they are more common. *Pilularia* is a second genus of the family with thread-like leaves, and spherical pill-like conceptacles. Our single species occurs in California, Oregon, and Arkansas.

V. *Equisetales.*—About 25 species forming a single genus and family make up this order. There are two types of growth, both common species of *Equisetum,* which have received different popular names. One is the field horsetail, which appears in low sandy ground early in spring, sending up a flesh-colored stalk terminating in a cone, followed by the "horsetails," which are the vegetative parts of the plant, consisting of a central hollow stalk with angular whorled branches. The leaves are reduced to sheaths encircling the stem. Under the surface-shields that cover the cone, the spores, which in mass resemble a fluffy mold, are borne in sporangia. The peculiar appearance of the spores is due to the fact that each is surrounded by an outer covering which splits spirally into four branches arranged cross-like at one end of the spore. These are exceedingly hygroscopic, and they absorb water and coil up at the slightest breath; then uncoiling as soon as the moisture dries, they jostle each other about. The purpose of this mechanism is to scatter the spores gradually from the sporangia at maturity. The second type of *Equisetum* grows on banks with stiff, jointed, rush-like, often clustered stems surrounded at the joints by a light-colored sheath. These also bear cones in late spring similar to those of the field-horsetail. These plants are sometimes called "scouring-rushes," from the fact that their roughness caused by silica in the epidermis led to their use for scouring floors and woodenware.

VI. *Isoetales.*—This order likewise contains a single genus (*Isoetes*) and family. The plants are aquatic, either growing submerged or on the shores of ponds and rivers. They consist of a short fleshy base, bearing a cluster of leaves which are broadened at the base and contain an axillary sporangium, and end in awl-like joints. The position of the order is problematical, as these obscure plants seem to show unexpected affinities with several other groups. They are eusporangiate and produce spores of two sorts.

VII. *Lycopodiales.*—This order contains the ground-pines or club-mosses and the selaginellas or little club-mosses, which are alike in producing their spores in the axils of leaves, but differ in the spore-characters. The club-mosses (*Lycopodium*) have yellow dust-like spores, which are used commercially under the name of lycopodium powder for the relief of chafing and for producing flash-lights, since they contain a large amount of oil and are highly inflammable. *Selaginella,* on the other hand, produces two kinds of spores — *microspores,* from which develop the male prothalli, and *macrospores,* from which develop the female prothalli. The lycopods are familiar as Christmas greens, but are rarely seen in cultivation. Over 100 species are known of which 17 are found within the limits of the United States. *Selaginella,* on the other hand, is frequent in cultivation, some of the species being exceedingly delicate and graceful; but most of our native species are inconspicuous and little known. The "resurrection-plant" has already been mentioned. Some of the tropical species attain enormous size as climbing-plants. Over 600 species have been described, of which 27 are found in the United States. A third family is represented in the Southern States by a leafy epiphyte (*Psilotum*). Two other small genera occur in Australia and neighboring islands.

Lucien M. Underwood,
Professor of Botany, Columbia University.

Feronia, fĕ-rō'nĭ-a, (1) An ancient Italian goddess, who presided over woods and orchards. The ancient grove, not far from Anxur (Terracina), was consecrated to her, and is very celebrated. Emancipated slaves received a cap in her temple as a badge of freedom. (2) A genus of beetles of the family *Carabidæ.* (3) A genus of plants allied to the orange.

Ferrand, Marie Louis, mä-rē loo-ē fĕ-räṅ, French soldier: b. Besançon, France, 12 Oct. 1753; d. Santo Domingo, 7 Nov. 1808. He served as a volunteer in the American Revolution, was imprisoned during the French Revolution as a friend of Lafayette, but was released and placed in command of a brigade in the armies of Ardennes and Sambre-et-Meuse. He went with General Leclerc to Santo Domingo 1801, succeeding Le Clerc as governor-general 1802. He was besieged by General Dessalines 1804, but withstood until the arrival of reinforcements under Admiral Missiessy, holding the eastern part of the island for several years, but, defeated at Paolo Fincado by Ramireshu, he shot himself on the battlefield.

Ferrara, fĕr-rä'rä, a province of Italy; on the north boundary is the Po River and on the east the Adriatic Sea; area, 1,144 square miles. The low ground is marshy, but good crops are raised on the uplands. The climate is unhealthful. Ferrara was once a duchy of Italy; it was held by the House of Este as a papal fief till 1597. It became a part of the States of the Church in 1598. In 1860 it was incorporated into the kingdom of Italy. Pop. 271,776.

Ferrara, Italy, city, capital of the province of Ferrara, 26 miles north-northeast Bologna, in a fertile but unhealthy plain, at a short distance from the north branch of the Po. It is a large and well-built town, with spacious and regular streets, and is enclosed by a wall seven miles in circuit. It is defended on the west side by a citadel regularly fortified. In the middle of the city is a castle, flanked with towers, and surrounded by wet ditches, which was once the residence of the dukes. Ferrara, though still retaining many traces of its former grandeur, has long been falling into decay; its pavements are overgrown with grass, and the staircases and balconies of many of its noble palaces are overrun with ivy, while others are without either doors or windows. The population has also fallen to one fourth of its former amount. It has a cathedral and numerous churches, most of which contain valuable paintings, together with some interesting specimens of sculpture. There are here a public gallery of paintings, called the Palazzo del Magistrato, containing many excellent works by the leading painters of the Ferrara school, of which Dosso

Dossi was one of the leaders. The city contains also a school of medicine and jurisprudence, and a public library containing about 100,000 volumes and 900 manuscripts, the latter including some of those of Ariosto and Tasso. The house in which Ariosto was educated, and that in which he lived during his latter years, and known by the names respectively of the Casa degli Ariosti and the Casa d'Ariosto, are shown to strangers. The latter is now national property, and is ranked among the national monuments. Another object of interest is the cell in the Hospital of St. Anna, in which Tasso was imprisoned. The house occupied by Guarini, the author of the Pastor Fido — the Casa Guarina — is still inhabited by the marquises of that name. Ferrara is an archbishopric: the bishopric dates from 661; its archbishopric was founded by Clement XII. in 1735. It carries on some trade in corn and other produce of the soil. There are manufactures of silk ribbons, wax candles, and brazen utensils; tanneries and glass works. Pop. of the commune (1901) 87,-648.

Ferrari, Gaudenzio, gâ-dĕn'dzē-ō fĕr-rä'rē, Italian painter: b. Valduggia, Piedmont, 1484; d. Milan 31 Jan. 1549. A scholar of Andrea Scotto, he also caught some inspiration from Da Vinci and Raphael. The chief characteristics of his style are correct and vigorous delineation, strong but often hard coloring, considerable power of invention, and skill in the arrangement of drapery. He executed innumerable paintings both in fresco and in oil, the greater part of which are possessed by the Lombard galleries. His most comprehensive work, the frescoes at Varallo, in Piedmont, represents the Passion; another good specimen of his work, the 'Martyrdom of St. Catharine,' is in the Brera Gallery at Milan. He died at Milan in 1549. The chief of his pupils was Andrea Solario. See Colombo, 'Vita di Ferrari' (1881).

Ferrari, Giuseppe, gwē-sep'pā fĕr-rä'rē, Italian philosopher and historian: b. Milan, Italy, 1812; d. Rome 1 July 1876. He wrote: 'On Error' (1840); 'Campanella's Religious Opinions' (1840); 'Machiavelli as Judge of the Revolutions of Our Time' (1849); 'Philosophy of Revolutions' (1851); 'History of Italian Revolutions, or Guelphs and Ghibellines' (1856–8); etc.

Ferrari, Paolo, Italian dramatist: b. Modena 5 April 1822; d. Milan 9 March 1889. He produced his first comedy, 'Bartolommeo il Calzolajo,' in 1847. Of his many later works, 'Goldoni' (1852), and 'Parini e la Satira' (1857) rank as the finest examples of modern Italian comedy, and are distinguished — as, indeed, are most of his plays — by a piquancy and sparkling dialogue, as well as cleverness of construction and occasional sharp contrasts, such as have been mostly identified with French comedy. A collection of his 'Opere drammatiche' was published at Milan in 14 volumes (1877–80). In 1860 he became professor of history at Modena, and afterward in the Academy at Milan.

Ferraris, Carlo Francesco, kar'-lō frän-chĕs'kō fĕr-rä'rēs, Italian political economist and statistician: b. Moncalvo, Alessandria, Italy, 15 Aug. 1850. In 1878 he was appointed professor extraordinary in the University of Pavia and in 1885 professor of statistics at Padua. Among his works are: 'La Statistica e la Scienza delle Amministrazione nelle Facultà Giuridiche' (1878); 'Moneta e Corso Forzoso' (1879); 'Saggi di Economia Statistica e Scienze delle Amministrazione' (1880); 'La Statistica del Movimento dei Metalli Preziosi fra l'Italia e l'Estero' (1883); 'L'assicurazione obbligatoria e la risponsibilita dei Padroni, ed imprenditori' per gli sufortuni sul lavoro' (1890); 'Principii di scienza bancaria' (1892).

Ferraris, Galileo, gä-lē-lā'ō fā-rä'rēs, Italian physicist and electrician: b. Livorno, Piedmont, 1847; d. 1897. He was graduated in civil engineering at the Royal School of Engineering' (1869). On being appointed professor of physics in the Industrial Museum and in the Military College at Turin, he devoted himself to the study of technical physics and was in a short time recognized as one of the foremost electricians in Europe. In 1885 his investigations into the properties of various electrical transformers resulted in the discovery of the rotatory magnetic field, produced by two alternating currents with a quarter difference of phase. This discovery made possible the two-phase motor. In 1893 he published a theory of the single-phase alternating motor, and to him the present development of alternating currents must largely be credited. His works on such subjects are standard authorities, and among them must be mentioned: 'On the Difference of Phase of Currents'; 'On the Lag of Induction'; and 'On the Waste of Energy in Transformers' (1887).

Ferrate, fĕr'-āt, in chemistry, a salt made of ferric acid, a weak, unstable compound of iron and oxygen, with bases. See Iron.

Ferrazzi, Giuseppe Jacopo, yä'kō-pō gwē-sep'pā fĕr rät'sē, Italian author: b. Cartigliano, Italy, 20 March 1813; d. Bassano, Italy, 1881. He published: 'Hand-books to Dante' (1865–77); 'Torquato Tasso: a Biographical, Critical, and Bibliographical Study' (1880); and studies of Ariosto, besides an 'Italian Anthology' (1858–9).

Ferree, James Barr, American architect and art critic: b. Philadelphia, Pa. He was graduated from the University of Pennsylvania 1884. He is the president of the department of architecture in the Brooklyn Institute of Arts and Sciences; is a member of several American and foreign architectural societies, and has written many professional papers for leading architectural and other periodicals.

Ferreira, Antonio, äṅ-tō'nē-ō fĕr rā'ī-rä, Portuguese poet: b. Lisbon, Portugal, 1528; d. 1569. He held a professorship at the University of Coimbra, and subsequently became judge of the supreme court at Lisbon. During his leisure he composed sonnets, odes, and epigrams, which earned for him the title of the "Portuguese Horace." His high literary reputation, however, is due to his 'Epistles' and the tragedy of 'Inez de Castro,' the second regular tragedy produced in Europe. The subject is a popular Portuguese legend; and the play is modeled upon the Greek tragic drama.

Ferreira de Vasconcellos, Jorge, zhōr'zhā fĕr-rā'i rä dā vas"kon-sel'ōsh, Portuguese dramatist: b. Coimbra or Montemor o Velho; d. 1585. His prose comedies, 'Euphrosyne' (1560); 'Usilippo' (1618); 'Aulegraphia'

(1619), are strictly national, and are valuable both philologically and for the proverbs in which they abound. He wrote also a romance of chivalry, 'The Triumph of Sagramor' (1567).

Ferreiro, fĕr-rā'ĭ-rō, a Brazilian tree-frog (q.v.).

Fer'rel, William, American meteorologist: b. Bedford County, Pa., 1817; d. 1891. He was graduated at Bethany College, Virginia, in 1844, and early attracted attention by his researches in meteorology, of which science he was the first to propound the fundamental principles. From being an associate in the work of putting forth the 'Nautical Almanac' he was appointed to the United States Coast and Geodetic Survey. From 1882 to 1886 he was an assistant in the Signal Service Bureau, and the maxima and minima tide-predicting machine which he invented has been used for many years in government coast surveys. Among his writings are: 'Popular Treatise on the Winds, Monsoons, Cyclones, etc.' (1889); 'Tidal Action'; 'Meteorological Researches.'

Ferreras, Juan de, hoo än' dā fĕr-rā'ras, Spanish historian: b. Labañeza, Spain, 7 June 1652; d. 8 June 1735. He was a scholarly priest, whose careful 'History of Spain' (1700–27) is authoritative for the period prior to 1598; his 'Poems' (1726) are less important.

Fer'rers, fĕr'ėrz, **Norman Macleod,** English mathematician: b. Gloucestershire 11 Aug. 1829. He was educated at Eton and Gonville and Caius College, Cambridge, of which latter institution he has been master from 1880. He has published: 'A Treatise on Trilinear Coordinates' (1861); 'A Treatise on Spherical Harmonics' (1877).

Ferret, a small and slender variety of polecat (q.v.), usually an albino, yellowish white, with pink eyes. It is bred chiefly as a domestic exterminator of mice and rats, and is used also in rabbit hunting. Unlike the ordinary polecat, it is exceedingly sensitive to cold, and must be well protected in northern climates which do not at all affect the polecat. Though bred in confinement, the ferret exhibits no affection, even for its master; and must be carefully secured, lest it escape and do injury. It has been known to hurt infants, and, if it gets at poultry, it will kill far more than it can eat. The female even, at times, devours her young. A cross between the ferret and the polecat is sometimes used.

Ferret, Col de, cōl de fē-rā, a pass of the Alps, in Switzerland, connecting Orsières, in the latter country, with Cormayeur, in Italy. Height 8,320 feet above sea-level. See ALPS.

Ferreting, the sport, well known in England, of chasing rabbits or hunting vermin (rats) with trained ferrets (q.v.). To pounce upon the victim and kill ("pith") it by a single bite in the neck, is regarded as a mark of high excellence in a ferret by ferreters. The principal use of ferrets, however, is not to kill the prey, but to go into their burrows and hiding places, muzzled, and drive out the animals.

Ferri, Ciro, chē'rō fĕr'rē, Italian painter, architect, and engraver: b. Rome 1634; d. there 4 Sept. 1689. He was a pupil and imitator of Pietro da Cortona, but displays less grace and less richness of color than his master. His canvases are scattered through Italy. He completed the frescoes in Pitti Palace, begun by da Cortona, and among his other paintings are the ceiling of the Annunziata and the cupola of St. Agnese, Piazza Navona, Rome, unfinished; 'Repose in Egypt'; 'Alexander Reading Homer'; 'Death of Dido,' Dresden; 'Triumph of Bacchus,' London. Among his architectural pieces are the altars of Chiesa Nuova and other churches in Rome. He left a great number of etchings.

Ferri, Enrico, en rē'kō fĕr'rē, Italian sociologist: b. San Benedetta-Po, Mantua, 25 Feb. 1856. He was educated at Bologna, Pisa, and Paris, and was admitted to the bar. He practises law at Rome, having been a member of the Chamber of Deputies since 1886, representing a socialistic following. Among his works are: 'Sociologie Criminelle' (1893, English translation 1896); 'La Scuola positiva di dirrito criminale' (1883); 'Difese pmali e studi di giurisprudins a' (1898); 'Deliquenti nell' arte' (1901).

Ferri, Luigi, loo-ē'jē fĕr'rē, Italian philosopher: b. Bologna 1826; d. Rome 1895. He entered the normal school, Paris, 1847, teaching philosophy in Châlon, Evreux, Dieppe, Blois, and Toulouse 1850–5. Returning to Italy he became secretary of public instruction 1860, professor of philosophy and history at the Institute of Florence 1863, and at the University of Rome 1871. Among his works are: 'Il Genio d'Aristotele' (1866); 'Studii su Leonardo da Vinci' (1871); 'Il senso commune nella filosofia' (1872); 'Sulla dotrina psicologica dell' associazione' (1878); 'la Psicologia di Pietro Pomponazzi' (1877); and in French 'Essai sur l'histoire de la philosophie en Italie au XIXme siècle' (1869); and 'la Psychologie de l'Association depuis Hobbes jusqu'à nos jours' (1883).

Ferric Oxide, or **Sesquioxide of Iron.** See HEMATITE; IRON.

Ferricyanide of Potassium. See HYDROCYANIC ACID.

Ferrier, fĕr'ĭ-ėr, **David,** Scottish neurologist: b. Woodside, near Aberdeen, 1843. In 1872 he became professor of forensic medicine in King's College, London, a chair which he exchanged in 1889 for that of neuro-pathology, specially founded for him. He has gained a wide reputation by his investigations of the structure of the brain, particularly in connection with the localization of its functions. His results are stated in his works on the 'Functions of the Brain' (1876); and 'Cerebral Localization' (1878). His researches necessitated a large number of experiments on living animals, and he has, in consequence, been strongly attacked by the anti-vivisectionists.

Ferrier, Joseph Marie Augustin Gabriel, zhō-zeph mä-rē ō-güs-tăṅ gä-bri-el, French painter: b. Nimes, France, 29 Sept. 1847. He studied under Lecocque Boisbaudran. His work has been recognized as vigorous and elevated. He won the Grand Prix de Rome in 1872, and was decorated with the cross of the Legion of Honor in 1884. Among well-known works of his are: 'David Conqueror of Goliath,' in the Nimes Museum, and 'Saint Agnes, Martyr,' in the museum at Rouen.

Ferrier, Susan Edmonstone, Scottish novelist: b. Edinburgh, Scotland, 7 Sept. 1782; d. there 5 Nov. 1854. She was an intimate friend of Sir Walter Scott and of some of the most eminent literati of her day. She wrote three novels: 'Marriage' (1818); 'The Inheritance' (1824); and 'Destiny, or the Chief's Daughter' (1831). They are vigorous and lively pictures of Scottish life and character, but exhibit a certain hardness and want of sympathy at times.

Ferris, Albert Warren, American physician: b. Brooklyn, N. Y., 1856. He was graduated at the New York University 1878, and at the Columbia University College of Physicians and Surgeons 1882. He became assistant in neurology, Columbia University, 1893, and assistant in medicine in the New York University medical department 1898. He has been an editor of the 'Medical Critic' since 1901.

Ferris, George Titus, American writer on music. His works include: 'Great German Composers' (1879); 'Great Italian and French Composers' (1879); 'Great Singers' (1880–1); 'Great Violinists and Pianists' (1881).

Ferris, George Washington Gale, American engineer: b. Galesburg, Ill., 14 Feb. 1859; d. Pittsburg, Pa., 22 Nov. 1896. He was graduated at Rensselaer Polytechnic Institute in 1881; went to Pittsburg, Pa., in 1892, while in the employ of the Louisville & Nashville Railroad, to inspect the structural work of the railroad bridge at Henderson, Ky. About this time he conceived the idea of a gigantic revolving wheel which he built in Pittsburg and erected for the World's Columbian Exposition in Chicago in 1893. The wheel could hold more than 1,000 passengers, and during the Exposition it was one of the great attractions.

Ferris, Isaac, American Dutch Reformed clergyman and educator: b. New York 9 Oct. 1798; d. Roselle, N. J., 1873. He was graduated at the Reformed Dutch Seminary, New Brunswick, N. J., 1820; was pastor at New Brunswick 1821–4; Albany 1824–6, and New York 1836–53. He was chancellor of the University of the City of New York 1852–70.

Ferris, Mary Lanman Douw, American author: b. Poughkeepsie, N. Y., 22 May 1855. She was married to M. P. Ferris (q.v.) 4 Sept. 1879. She is the founder of the Daughters of the Cincinnati, and was instrumental in establishing the museum in Van Cortlandt Park, New York, now maintained by the Colonial Dames. She is the editor of the 'Bulletin of the Society of American Authors,' and has published: 'Dutch Nursery Rhymes of Colonial Times'; 'Random Rhymes of Old Dutch Times'; 'History of Fort Crails'; etc.

Ferris, Morris Patterson, American lawyer: b. New York 3 Oct. 1855. He is a son of I. Ferris (q.v.) and was graduated from the law department, University of New York, 1876. He is president of the Yonkers Historical and Library Association; secretary of the Sons of the Revolution; secretary of the Colonial War Lake George Monument Committee, secretary of the New York State Historical Association, registrar of the Society of the War of 1812, and treasurer of the Society of American Authors.

Ferro, fĕr'rō, or **Hierro,** yĕr'rō, the most westerly of the Canary Islands, and the smallest of those which are inhabited; longitude of the western extremity, 18° 9'. It is about 18 miles long and 9 miles broad. It is a rocky, volcanic island, rising to the height of over 4,100 feet, and has numerous extinct craters, and a number of warm springs. It is by no means fertile, but good wine and brandy are made, and excellent figs are grown on the island. This island was once considered the most western point of the Old World, and geographers reckoned longitude from it. For this purpose the longitude of Ferro was in France taken as exactly 20° west of that of Paris, though this meridian really passes some miles to the east of the island. German geographers adhered longest to the meridian of Ferro in constructing their maps. Pop. 5,980.

Ferrol, fĕr-rōl', or **El Ferrol,** Spain, seaport in the province of La Coruña; about 12 miles northeast of the town of La Coruña; on the Bay of Betanzos, a few miles from the ocean. The bay forms one of the best natural harbors in Europe, and the narrow channel which leads to it is defended by the forts San Felipe and Palma. Charles III. built here an arsenal for the Spanish navy, which is still in use. The manufactures consist chiefly of swords, cutlery, and military and naval equipments, sail-cloth, and leather. The sardine fishery is also important. The principal imports are coal, iron, timber, cotton, and grain; the chief exports are fish, iron, and vinegar. Pop. (1900) 25,281.

Ferrotype, or **Energiatype,** in photography, a process first made public by Robert Hunt in 1844, in which the negative was developed by a saturated solution of protosulphate of iron, with mucilage of gum-arabic, and fixed by soaking in water to which a small quantity of ammonia or hyposulphite of soda had been added. See PHOTOGRAPHY.

Ferrous Sulphate, Ferrous Compounds. See IRON.

Ferry, Gabriel, gä-brī-el fĕ-rē, the Elder (pseudonym of EUGÈNE LOUIS GABRIEL FERRY DE BELLEMARE, ü-zhen loo-ē gä-brī-el fĕ-rē de bel-mar), French author: b. Paris, France, 30 May 1809; d. 1852. His stories appeared first serially in the 'Revue des Deux Mondes.' He made repeated voyages to the United States; in his last voyage, to California, he lost his life in the burning at sea of the ship Amazon. Among his tales are: 'The Woodranger'; 'Hunting with Cossacks'; 'Costal the Indian'; 'Scenes of Military Life in Mexico'; 'The Squatters.'

Ferry, Gabriel, the Younger, French author, dramatist, and novelist: b. Paris 30 May 1846. He is a son of Gabriel the Elder and employs the same pseudonym. He has written plays: 'Réginah' (1874), being one of the best; while his miscellaneous prose includes: 'The Last Years of Alexandre Dumas, 1864–70' (1883); 'Balzac et ses amies' (1888); 'The Exploits of Cæsar: a Parisian Novel' (1889).

Ferry, Jules François Camille, zhül frän-swä cä mēl fĕ-rē, French statesman: b. Saint Dié, France, 5 April 1832; d. Paris 17 March 1893. He was admitted to the Paris bar in 1854, and speedily identified himself with the opponents of the empire. His hostility was carried into journalism, and a series of articles in the 'Temps' ('Times'), were republished as 'The Fantastic Tales of Haussmann' (1865). In 1869 he was elected to the National Assembly, where he voted against the war with Prussia; and during the siege of Paris by the Germans (1870–1) he played a prominent part as central mayor of the city. He was minister to Athens 1872–3, and in 1879 became minister of public instruction and began an agitation against the Jesuits. Their expulsion was effected, and brought about the dissolution of the ministry in September 1880. M. Ferry then formed a cabinet, which remained in office till November 1881. In February 1883 he again became premier, with a policy of "colonial expansion," involving a war in Madagascar and the invasion of Tonquin, where a disaster to the French troops brought about his downfall in March 1885. In 1890 he was made senator. His 'Discours et Opinions' appeared in 7 volumes (1893–8).

Ferry, Orris Sandford, American statesman and soldier: b. Bethel, Conn., 1823; d. 1875. He was graduated at Yale in 1844. After filling important political places in his native State he was in 1859 elected to Congress as a Republican, and sat as one of the famous Committee of Thirty-Three appointed to consider and report upon the condition and relations of the seceded States. He was colonel of the Fifth Connecticut Volunteer Infantry (1861), and served from 1862 to the end of the war as brigadier-general of volunteers. He was elected to the United States Senate as a Republican in 1866, and re-elected in 1872.

Ferry, Thomas White, American politician: b. Mackinac, Mich., 1 June 1827; d. Grand Haven, Mich., 14 Oct. 1896. He served in the State legislature and from 1865 to 1871 was a Republican member of Congress. He was elected to the United States Senate; and on the death of Henry Wilson was acting Vice-President of the United States from 1875 to 1877.

Fersen, fĕr'sen, **Hans Axel,** Count von, Swedish military officer: b. Stockholm, Sweden, 1755; d. there 20 June 1810. He came to America on the staff of Rochambeau; fought under Lafayette and received from Washington the Order of the Society of the Cincinnati. Later he went to France, where he became a favorite at court, and was the disguised coachman at the flight of the royal family from Versailles during the Revolution. He returned to Sweden, where he was received with honor, and in 1801 was made grand marshal of that country. On suspicion of complicity in the death of Prince Christian of Sweden, he was seized by a mob while marshaling the funeral procession, and tortured to death.

Fertilization of the Ovum. See Embryology.

Fertilizers. Any substance applied to the soil to aid the growth of plants may properly be called a fertilizer. The name has, however, become associated with a class of materials manufactured and sold for this purpose, the handling of which now constitutes an important industry.

The constituents of the plant that it derives from the soil are nitrogen, phosphorus, sulphur, potassium, sodium, calcium, magnesium, iron, aluminum, manganese, silicon, chlorine. Of these, nitrogen, phosphorus or phosphoric acid, and potassium or potash, are the substances most likely to be deficient in the soil, and therefore the ones that are contained in fertilizers. A fertilizer may contain any one or more of these substances.

The chief distinction between the functions of farm manure and commercial fertilizers may be stated in a general way to be that farm manure increases crop production by improving the condition of the soil, while the commercial fertilizers act directly as a plant-food without materially affecting soil structure.

It is evident, therefore, that commercial fertilizers are not an adequate substitute for farm manure or green manures for producing permanent improvement. Their function consists in supplementing the available supply of plant-food in a soil which may be deficient in any one or more of the substances usually contained in fertilizers. On virgin soils commercial fertilizers are generally superfluous; but as loss of plant-food goes on under cropping, restitution must be made and, as this is usually not adequately done with farm manure, fertilizers are finally called upon.

In regions where there is large loss of plant-food from the soil due to leaching, there must be a large excess of potential fertility in order that the growing crop shall at all times be supplied with available plant-food. A deficiency in any constituent will check growth by compelling the plant to depend upon a less readily available supply. Commercial fertilizers are useful by presenting readily available food to the plant when it is beginning growth, and when a deficiency in the supply is likely to produce a permanent injury.

As the price of land increases, as the cost of labor becomes greater, and as the value of the crop augments it becomes more important that maximum crops shall be raised, and for these reasons commercial fertilizers have greatest sale where agriculture is most intensive. There are also many special crops requiring more of one plant-food than of another, and the needs of these can best be met by the use of commercial fertilizers.

Historical.— The value of animal excrements applied to soils on which crops were grown has been appreciated by the husbandman as far back as records go. Why this manure is beneficial, and what relation its constituents bear to those of plants, are matters which have only been worked out during the last century, and knowledge of which has led to the use of fertilizers composed of mineral salts, commonly known as commercial fertilizers.

The earliest record of the use of mineral salts for increasing the yield of crops is contained in a book entitled 'A Discourse Concerning the Vegetation of Plants.' The title page also contains the following announcements: "Spoken by Sir Kenelm Digby, at Gresham College, on the 23d of January 1660. (At a meeting of the Society for Promoting Philosophical Knowledge by Experiments. London. Printed for John Williams, in Little Britain, over against St. Botolph's Church, 1669.)" The author advocates the use of saltpetre to increase the yield of crops, and says: "By the help of plain saltpetre, dilated in water and mingled with some other fit earthy substance, that may familiarize it a little with the corn into which I endeavored to introduce it, I have made the barrenest ground far out-go the richest, in giving a prodigiously plentiful harvest." His dissertation does not, however, show any true conception of the reason for the increase in the crop through the use of this fertilizer. The almost total absence of any knowledge of the composition of plants, and the crude state of chemistry at that time, made this quite impossible.

It was not until 1804 that any light was thrown upon the subject. In that year was published ‘Recherches Chimique sur la Végétation,’ by Theodore de Saussure. This brilliant French investigator was the first to appreciate the significance of the ash ingredients of plants; to point out that without them plant life was impossible, and to show that only the ash of the plant was derived from the soil.

Justus von Liebig is commonly regarded as having laid the foundation upon which the commercial fertilizer industry has been built. Certainly his reports to the British Association in 1840 and again in 1842 made the British agriculturists regard as they had never done before the importance of a sufficient supply of certain readily soluble mineral substances in the soil. He supported the contention of De Saussure regarding the importance of mineral matter in the plant, and its extractions from the soil. He refuted the theory, at that time popular, that plants absorbed their carbon from humus, but made the mistake of attaching little importance to the presence of humus in the soil. He showed the importance of potash and phosphates in manures, and in his earlier writings spoke of the value of nitrogen for fertilizing crops, but afterward made the mistake of denying the usefulness of nitrogenous manures for plants, holding that the ammonia washed down by rain affords a sufficient supply.

By the middle of the 19th century it was well understood that potash, phosphoric acid, and nitrogen were valuable constituents of fertilizers, and that the other mineral elements of plant-food, with the occasional exception of calcium, were always present in sufficient quantity in arable soils. It has since been shown that the family of plants known as the *Leguminosæ* have the ability to secure a large part, at least, of their nitrogen from the air, and that as these plants are very rich in nitrogen they leave a supply of nitrogen in organic matter in the soil when plowed under, or even when the roots alone are allowed to remain in the soil.

Direct and Indirect Fertilizers.— Fertilizers that add to the soil only mineral constituents that are taken up by plants may be called direct manures. However, soil amendments are sometimes used which contain in addition to or in place of these substances certain constituents that increase the crop without adding to the supply of the fertilizing constituents. These may be called indirect fertilizers. Farmyard manure is an example of this, as in addition to the mineral constituents of the plant it adds a quantity of purely organic matter which, through its decomposition, exerts a very beneficial effect upon crop-production.

Complete and Incomplete Fertilizers.— Fertilizers, containing nitrogen, phosphoric acid, and potash, mixed together so that an application of the preparation will result in bringing each of these substances in contact with the soil wherever applied, are called complete fertilizers. The proportions in which the constituents are mixed vary with the different brands and factories. Sometimes a fertilizer of this kind will be advertised for use on a certain crop, and will contain the nitrogen, phosphoric acid, and potash in the proportion in which the manufacturer believes they will produce the best yields of that crop. He has, however, no means of knowing the requirements of the soils on which the fertilizer is to be used.

Incomplete fertilizers contain only one or two of the customary fertilizer ingredients.

Available and Unavailable Fertilizing Material.— The fertilizing constituents in a fertilizer may be present in a readily soluble or a difficultly soluble condition, depending upon the chemical combinations and, to some extent, upon the physical condition in which they are found. Thus phosphoric acid when in the form of phosphate rock as it is taken from the deposits is a very difficultly soluble substance, and plants can avail themselves of it only in small quantities. After the same rock has been treated with sulphuric acid the phosphoric acid is in a form in which it can be readily used by plants. To a more limited extent the same is true of the phosphoric acid in basic slag, which, when the slag is in an unground condition, is not of much use to plants, but when the slag has been finely ground furnishes a valuable form of plant-food.

When the fertilizing material is in a condition in which it can be readily used by the plant it is said to be «available,» and when it can be used only with great difficulty it is said to be «unavailable.» It is important that the purchaser should know in what form the constituents are present in a fertilizer.

Nitrogenous Fertilizers.— Nitrogen is taken up by most plants only in the form of a soluble salt; hence for the cereals and many other crops it is desirable either to have it in this form or to incorporate it in the soil in a condition in which it will readily be converted into a soluble salt. Plants like the clovers, alfalfa, peas, beans, etc., have the power of using the nitrogen of the air, and hence do not require nitrogenous fertilizers in such large amounts. These plants may be used to increase the supply of nitrogen in the soil. Nitrogen is the most expensive constituent of fertilizers, and is extremely important, as it is used in large amounts by plants and is likely to be deficient in soils. The form in which nitrogen is present in a fertilizer may make a great difference in its value and in the way in which it can be best applied. Nitrogenous fertilizers differ in having their nitrogen either in the form of a soluble salt or combined as organic material. Nitrate of soda and sulphate of ammonia are the forms in which soluble nitrogen salts are found on the market.

Ammonium Sulphate.— When coal is distilled a portion of the nitrogen is liberated as ammonia, and is found in the ammoniacal liquor which condenses when the products of distillation are cooled. Coal is distilled for the production of coal-gas for illuminating purposes, and also in the manufacture of coke. Gas-works and coke-oven thus provide a large share of ammoniacal liquor, which forms the raw material for the manufacture of ammonium salts. Another source of ammonia is the liquid condensed from the «water-gas» formed when a current of steam is forced over red-hot coal. The product obtained in any of these processes is a mixture of ammonium sulphide, carbonate, thiosulphate, thiocyanate, and chloride, dissolved in water.

To prepare this for use the liquid is heated and lime is added. The ammonia volatilizes partly as carbonate and sulphide, and partly as free ammonia, and is received in sulphuric acid, forming ammonium sulphate and driving off as gases carbon dioxide and sulphuretted hydrogen. The liquid is then evaporated in leaden pans until it crystallizes.

The world's output of ammonium sulphate in 1900 is placed at 493,000 tons, of which 270,000 tons were used as fertilizer.

Chemically pure sulphate of ammonia contains 21.2 per cent of nitrogen. The commercial product contains about 20 per cent of nitrogen. It is the most concentrated form in which nitrogen can be purchased for use as a fertilizer.

Nitrate of Soda.— This fertilizer now constitutes the principal source of nitrogen in artificial manures, having largely taken the place of Peruvian guano, which was extensively used for many years, and the profitable use of which did much to promote the extensive use of commercial fertilizers. The salt occurs in the crude condition called caliche, in enormous deposits, principally in the province of Tarapaca in northern Chile. The earlier records of these deposits extend back to 1820, but it was not until several years later that they were exploited. The portion of the country in which the deposits lie is a sandy desert where rain never falls. The altitude is 3,000 to 4,000 feet above the sea-level. The deposits are attributed to the action of minute organisms fixing in the soil, through countless ages, the nitrogen of the atmosphere, and leaving the product finally in the form of sodium nitrate that has crystallized out of solution in which it has at some time been held.

The raw product is found beneath a covering consisting of two layers, the upper one of sand and gypsum and the lower of baked clay and gravel. The thickness of the caliche varies from a few inches to 12 feet. It is extracted by boring through the upper layers and introducing a charge of blasting-powder, which, when fired, exposes a considerable quantity of the material. The nitrate is somewhat purified by crystallization before shipping. Iodine is a by-product in the purification process. The nitrate, when ready for shipment, contains about 96 per cent sodium nitrate, or about 16 per cent of nitrogen, 2 per cent of water, and small amounts of sodium chloride, sulphates, and insoluble matter.

The development of the nitrate industry may be appreciated from the fact that the product, which amounted in 1884 to 550,000 tons, increased to 1,000,000 tons in 1890, and to 1,475,000 tons in 1900. The output is exported almost entirely to Europe and the United States. It is held by many persons who have examined these deposits that at the present rate of mining they will be exhausted by the year 1930, in which case a serious deficiency in fertilizer nitrogen will occur, unless a new supply shall meanwhile have been discovered.

Other Nitrogenous Fertilizers.— A method for preparing what promises to be a valuable nitrogenous fertilizer has lately been worked out by a German chemist. The chief point of interest in this fertilizer lies in the fact that the nitrogen it contains is derived from the air, thus making use of an inexhaustible supply of that material. No artificial method for the fixation of atmospheric nitrogen has up to the present time been sufficiently inexpensive to make it a commercial success. The method referred to consists in heating lime and coal in an electric furnace and passing nitrogen gas over them. The product, calcium cyanamide, was tested in pots of soil and in field-tests at the Darmstadt and Posen experiment stations, and found to decompose in the soil with the formation of ammonia and nitric acid, and to furnish plants with nitrogen.

Attempts have been made, especially in recent years, to produce nitrate fertilizers by combining by electrical means the nitrogen and oxygen of the air, but these have so far not been reduced to a practical basis. Experiments with this end in view are now in progress at Niagara Falls.

Organic nitrogenous fertilizers include cotton-seed meal (7 per cent nitrogen when free from hulls), linseed meal (5.5 per cent nitrogen), castor-pomace (6 per cent nitrogen), and a number of refuse products from packing-houses, consisting of red-dried blood (13 per cent nitrogen), black-dried blood (6 to 12 per cent nitrogen), dried meal (13 per cent nitrogen), hoof-meal (12 per cent nitrogen), ground fish (8 per cent nitrogen), and tankage (concentrated 10 to 12 per cent, crushed, 4 to 9 per cent nitrogen), also leather-meal, and wool- and hair-waste, which last two on account of their physical condition are of little value.

There is an evident advantage in the use of the soluble salts where quick action is desired. The nitrogen of sodium nitrate is in a form in which it may be utilized directly by the plant, while ammonium salts, owing to their rapid oxidation in the soil, are almost as available. The nitrate should be applied to the soil only when the crop is planted or is ready to use it, otherwise it is likely to leach out of the soil. Nitrogen in the form of organic matter must undergo chemical changes in the soil before it can be utilized by the plant, and hence such fertilizers should be applied to the soil some time previous to their use by the crop.

As regards the relative value of the nitrogenous fertilizers, an exact rating is difficult to attain, but a summary of the various tests indicates that when nitrate is rated at 100 per cent, ammonium sulphate may be taken as the same; blood and cotton-seed meal, 70 per cent; dried and ground fish and hoof-meal, 65 per cent; bone and tankage, 60 per cent; and leather, ground horn, and wool-waste range from 2 per cent to 30 per cent.

Phosphate Fertilizers.— By the term phosphate fertilizers is meant those substances that are used for manures chiefly because of the phosphorus they contain. The phosphorus is generally present in the form of a phosphate of lime, iron, and alumina mixed with other substances. Some of these phosphates also contain organic matter, in which case they generally carry some nitrogen, which adds something to their value as fertilizers. Phosphates associated with organic matter decompose more quickly in the soil than purely mineral phosphates, and are therefore more readily available fertilizers.

Bone-Phosphate.— The bones of animals have been for a great many years an important form of phosphate manure. Formerly bones were used entirely in the raw condition, either ground or unground. In the ground condition they are a more quickly acting fertilizer. Raw bones contain about 22 per cent phosphoric acid and 4 per cent nitrogen. The phosphoric acid is in the form of tricalcium phosphate.

At the present time most of the bone used as manure is first boiled or steamed. This frees it from fat and nitrogenous matter, both of which are used in other ways. Steamed bone is a more valuable fertilizer than raw bone, as the fat in the latter retards decomposition, and also because the steamed bone is in a better mechanical condition. The form of the phosphoric acid is the same as in the raw bone, and varies from 28 to 30 per cent, while the nitrogen is reduced to about 1½ per cent. Bone tankage, which has already been spoken of as a nitrogen fertilizer, contains from 7 per cent to 9 per cent phosphoric acid, largely in the form of tricalcium phosphate. All of these bone-phosphates are slow-acting fertilizers, and should be used finely ground, and for the permanent benefit of the soil rather than as direct plant-food.

Mineral Phosphates.— There are many natural deposits of mineral phosphates scattered over the earth, some of the most important of which are in America. The phosphorus in all of these is in the form of tricalcium phosphate, but the materials associated with it vary greatly.

Coprolites are concretionary nodules found in the chalk or other deposits in the south of England and in France, the name having been given them on the assumption that they consisted of fossilized animal excrement. They contain 25 to 30 per cent of phosphoric acid, the other constituents being calcium carbonate and silica.

Apatite is found in large quantities in the provinces of Quebec and Ontario, Canada. It occurs chiefly in crystalline form. The calcium phosphate of which it is composed is in one form associated with calcium fluoride, and in the other with calcium chloride. The Canadian apatite contains about 40 per cent phosphoric acid, being richer in this ingredient than that found elsewhere. Phosphorite is another name for apatite, but is chiefly applied to the impure amorphous form.

South Carolina phosphate has been mined since 1868. It occurs in the form of lumps from the size of a pebble to a mass weighing a ton. These are distributed through a deposit varying from 1 to 20 feet in thickness, which occurs both on the land and in the river beds. It contains from 26 to 28 per cent of phosphoric acid, and but a very small amount of iron and aluminum. As these substances interfere with the manufacture of superphosphates from the rock, their presence is very undesirable, rock containing more than 3 to 6 per cent being unsuitable.

Florida phosphates have been on the market since 1888. They occur in the forms of soft phosphate, a whitish product somewhat resembling clay, and largely contaminated with it; pebble phosphate, consisting of hard pebbles; rock or boulder phosphate, consisting as the name implies of rocks or boulders. Soft phosphate contains from 18 to 30 per cent of phosphoric acid, and on account of its being more easily ground than most of these rocks is applied to the land without being first converted into a superphosphate. Pebble rock constitutes the major portion of the Florida phosphate. It contains from 20 to 40 per cent of phosphoric acid, being very variable in composition. Rock or boulder phosphate is much more uniform in composition than the other kinds, but there is less of it. It contains about 40 per cent of phosphoric acid.

Tennessee phosphate was discovered in 1894. It differs from the Carolina and Florida phosphate in that it does not exist as nodules, pebbles, or boulders, but in veins and pockets, and does not need to be washed previous to its treatment. It contains from 30 to 35 per cent of phosphoric acid.

Basic slag, or, as it is also called, phosphate slag, or Thomas phosphate, is a by-product in the manufacture of steel from pig-iron rich in phosphorus. The phosphoric acid present is in the form of tetracalcium phosphate, $(CaO)_4P_2O_5$. It also contains calcium, magnesium, aluminum, iron, manganese, silica, and sulphur. On account of the presence of iron and aluminum, and because its phosphoric acid is more readily soluble than the tricalcium phosphate, the ground slag is applied directly to the soil without treatment with acid. It is produced in large quantities in England, Germany, and France. So successful has it proved as a fertilizer that a product known as "artificial Thomas phosphate" has lately been made in Germany.

Superphosphate Fertilizers.— In order to render more readily available to plants the phosphoric acid contained in bone and mineral phosphates, the raw material, purified by being washed and finely ground, is treated with sulphuric acid. This results in a replacement of phosphoric acid by sulphuric acid with the formation of monocalcium phosphate and calcium sulphate, with a smaller amount of dicalcium phosphate, according to the reactions:

$Ca_3(PO_4)_2 + 2H_2SO_4 = CaH_4(PO_4)_2 + 2CaSO_4$, and $Ca_3(PO_4)_2 + H_2SO_4 = Ca_2H_2(PO_4)_2 + CaSO_4$.

The tricalcium phosphate, being in excess of the sulphuric acid used, a part of it remains unchanged.

In the treatment of phosphate rock part of the sulphuric acid is consumed in acting upon the impurities present, which usually consist of calcium and magnesium carbonates, iron and aluminum phosphates, and calcium chloride or fluoride, converting the bases into sulphates, and freeing carbon dioxide, water, hydrochloric acid and hydrofluoric acid. The resulting superphosphate is therefore a mixture of monocalcium phosphate, dicalcium phosphate, tricalcium phosphate, calcium sulphate, and iron and aluminum sulphates.

In the superphosphates made from bone the iron and aluminum sulphates do not exist in any considerable amounts. However, as long as the phosphoric acid remains in the form of monocalcium phosphate the value of a pound of available phosphoric acid in the two kinds of fertilizer is the same, but the remaining tricalcium phosphate in the bone superphosphates has a greater value as before explained.

The superphosphates made from animal bone contain about 12 per cent available phosphoric acid and three or four per cent of insoluble phosphoric acid. They also contain some nitrogen. Bone-ash and bone-black superphosphates contain practically all of their phosphoric acid in an available form, but they contain little or no nitrogen. South Carolina rock superphosphate contains from 12 to 14 per cent available phosphoric acid, including from 1 to 3 per cent reverted phosphoric acid. The best Florida rock superphosphates contain from 17 per cent downward of available phosphoric acid, part of which is reverted. The Tennessee superphosphates vary from 14 to 18 per cent available phosphoric acid.

Reverted Phosphoric Acid.— On standing, a change sometimes occurs in superphosphates by which a part of the phosphoric acid becomes less easily soluble, and to that extent the value of the fertilizer is decreased. This change, known as «reversion,» is much more likely to occur in superphosphates made from rock than in those derived from bone. It will also vary in different samples, a well-made article usually undergoing little change even after long standing. It is supposed to be caused by the presence of undecomposed tricalcium phosphate, and of iron and aluminum sulphates.

The decrease in solubility of the superphosphate is due to the interaction of monocalcium phosphate and tricalcium phosphate leading to the formation of dicalcium phosphate, and perhaps to the formation of ferric and aluminum phosphates by the action of monocalcium phosphate upon the iron and aluminum sulphates.

Double Superphosphates.— In making superphosphates, a material rich in phosphoric acid must be used, not less than 60 per cent tricalcium phosphate being necessary for their profitable production. The poorer materials are sometimes used in making what are known as double superphosphates. For this purpose they are treated with an excess of dilute sulphuric acid; the dissolved phosphoric acid and the excess of sulphuric acid are separated from the mass by filtering, and are then used for treating phosphates, rich in calcium phosphate, forming superphosphates. The superphosphates so formed contain more than twice as much available phosphoric acid as those made in the ordinary way.

Relative Availability of Superphosphates.— Superphosphates and double superphosphates contain their phosphoric acid in a form in which it can be taken up by the plant at once. They are therefore best applied at a time when the crop is planted, or just before, or they may be applied when the crop is growing. In this respect their use differs radically from that of crude phosphates. Well-made superphosphates contain no free acids, and therefore are not injurious to vegetation unless used in excess.

Reverted phosphoric acid, although not soluble in water, is readily soluble in dilute acids. Its value as a ready source of food for plants has been the subject of much discussion among agricultural chemists. It is now quite generally believed that it furnishes an available supply of phosphoric acid to the plant. The American Association of Official Agricultural Chemists recognized this by adopting a statement of analysis which includes this form in the «total available phosphoric acid.»

Potash Fertilizers.— The production of potash fertilizers is largely confined to Germany, where are inexhaustible beds varying from 50 to 150 feet in thickness lying under a region of country extending from the Harz Mountains to the Elbe River, and known as the Stassfurt deposits. These deposits of potash salts have been mined since 1862, during which time they have constituted the world's principal supply of potash. They are operated by a syndicate comprising all the large owners, and maintaining a uniform price on the output.

Deposits have more lately been discovered in Thuringia, Brunswick, and Mecklenburg. The principal salts placed on the market are sylvine (potassium chloride); sylvinite, a mixture of sylvine, rock-salt, and kainite; carnallite (magnesium chloride and potassium chloride); schoenite (magnesium sulphate and potassium sulphate); kieserite (magnesium sulphate with carnallite); kainite (magnesium sulphate and potassium chloride, or magnesium and potassium sulphates and magnesium chloride); polyhalite (potassium, calcium, and magnesium sulphates).

In 1898 there were 1,330,505 tons of these salts produced, of which 1,056,226 tons were kainite, which is therefore the principal fertilizer produced.

The potash fertilizers contain their potassium either as chloride or sulphate. The chloride has the advantage of being more diffusible in the soil; but in most respects the sulphate is preferable. Potassium chloride has an injurious effect upon such crops as tobacco, sugar-beets, and potatoes. In tobacco the potassium chloride in the ash prevents the proper burning of the tobacco. In the case of clover, corn and grass, however, potassium chloride appears to have no harmful effects.

Kainite.— The potash contained in kainite is in the form of sulphate, but because of the large quantities of other salts it contains, chiefly sodium and magnesium chloride, it has the same effect upon plants as has the chloride. It contains from 12 to 20 per cent of potash, and 25 to 45 per cent of sodium chloride, with some chloride and sulphate of magnesium. Kainite should be applied to the soil a considerable time before the crop which it is intended to benefit is planted. It should not be drilled in with the seed. By this method of application the injurious properties of the chlorides will not affect the crop. Indirectly kainite serves to supply the plant with food other than potash. The salts associated with the potash, particularly the chlorides, aid plant-growth by making other substances in the soil, particularly phosphoric acid, more available to the plant, besides improving the physical condition of the soil.

Sylvinite.— This salt contains its potash both as chloride and as sulphate. It also contains sodium and magnesium chlorides. It contains about 16 per cent potash. Owing to the presence of chlorides it has the same effect as kainite.

Muriate (chloride) of Potash.— This is a more concentrated form of potash than either of those just mentioned. It contains about 50 per cent of potash, making it 80 per cent pure potassium chloride. The impurities are largely sodium chloride and insoluble mineral matter. A purer form of muriate of potash may be obtained which contains 98 per cent pure potassium chloride.

Sulphate of Potash.— High-grade sulphate of potash contains from 49 to 51 per cent of potash. Its advantage over muriate is that it is not, like the latter, injurious to any crops; but it has the disadvantage of being more expensive, and it has not, as has the chloride, indirect plant-feeding properties.

Schoenite.— This is a double sulphate of potash and magnesium. It contains about 26 per cent of potash. The cost of the potash is greater than in the muriate. The sulphate of magnesium it contains is supposed to have a beneficial effect upon the soil.

Other Fertilizing Materials.— There are a number of fertilizers not included in the classes already mentioned. Many of them are very valuable sources of fertility.

Wood-Ashes.— For some time after the use of fertilizers became an important farm practice, wood-ashes constituted a large portion of the supply of potash. They also contain considerable quantity of lime and a small amount of phosphoric acid. The product known as unleached wood-ashes contains 5 to 6 per cent of potash, 2 per cent of phosphoric acid, and 30 per cent of lime. Leached wood-ashes contain about 1 per cent of potash, 1.5 per cent of phosphoric acid, and 28 to 29 per cent of lime. They contain the potash in a readily available form as potassium carbonate. The lime conduces to a good physical condition of the soil.

Guano.— This fertilizer has been formed from the excrement and carcasses of sea-fowl. The composition of guano depends upon the climate of the region in which it is found. Guano from an arid region contains nitrogen, phosphoric acid, and sometimes potash, while that from a region where rains occur contains only phosphoric acid, the nitrogen and potash having been leached out. In a dry guano the nitrogen occurs as uric acid, urates, and in small quantities ammonium salts. A damp guano contains more ammonia. The phosphoric acid is present as calcium phosphate, ammonium phosphate, and as phosphates of other alkalies. A portion of the phosphate is readily soluble in water. All of the plant-food is thus either directly available or becomes so soon after admixture with the soil. The composition is extremely variable. Guano was formerly a very important fertilizing material, but the supply has become so nearly exhausted that it is relatively unimportant at the present time. South America, South Africa, Australia, and certain islands in the Pacific contribute to the supply.

Other fertilizers of less value are powder-waste, agricultural salt, cotton-hull ashes, coal-ashes, seaweed, king-crab, mussel and lobster shells, muck, peat, marl, tobacco stems and stalks, crude fish-scrap, wool- and hair-waste, sewage, street-sweepings, etc.

Lime.— The use of lime, either in the form of quicklime (CaO), air-slacked lime ($CaCO_3$), or gypsum ($CaSO_4$, $2H_2O$), also called "land-plaster," benefits greatly the physical condition of some soils, particularly those of heavy clay structure. Besides operating on the physical condition of the soil, it adds calcium and liberates a certain amount of plant-food held by the soil. Soils that contain free acid are greatly benefited by the application of caustic lime. Another function of lime in any of these forms is that of promoting nitrification.

Home Mixing of Fertilizers.— Fertilizers are ordinarily sold as (1) complete fertilizers containing nitrogen, phosphoric acid, and potash, which in different mixtures are to be found in different relative amounts; and (2) incomplete fertilizers, or raw material containing only one of these ingredients. Authorities at a number of the experiment stations have urged that it is in many cases more profitable for the farmer to purchase the incomplete fertilizers and mix them himself. The arguments advanced in favor of this practice are that the materials can be purchased more cheaply in that form than when mixed by the manufacturer; that they can be used in the proportion desired, which may effect a saving in the amount of some ingredient, and and that the form in which each ingredient is present is then known, which is not always the case when mixtures are purchased.

On the other hand, it is more difficult to obtain the raw materials from the small dealer, and when purchased they are not generally so finely ground as they are in the mixtures; and this in the case of the more difficultly soluble materials is a marked disadvantage.

State Control of Fertilizer Sales.— In most States in which fertilizers are largely used laws are in effect compelling manufacturers or dealers in fertilizers to state the actual amounts of the fertilizing ingredients contained in the fertilizers offered for sale, and also to state in what form each of these ingredients exists. A chemical control is provided and a penalty imposed for any failure to comply with the law. The control authorities publish each year a statement of the commercial value per pound of nitrogen, phosphoric acid, and potash in each of the various forms in which they occur in fertilizers. Fertilizer control is in most States attached to the State agricultural experiment stations, and information concerning the purchase and use of fertilizers can be obtained from these institutions.

Statistical.— The amount of fertilizers manufactured and consumed is increasing in all portions of the crop-producing world; and especially in the United States is there a rapid increase from one decade to another. In 1859 the value of the entire output of the fertilizer factories was $891,344; in 1869, $5,815,118; in 1879, $23,650,795; in 1889, $39,180,844; and in 1899, $44,657,385. Not all of this was used on farms in this country, there being $6,983,186 worth exported in 1899; but, partly to offset this, there was $1,492,019 worth imported. The imported fertilizers consisted largely of nitrate of soda, and potash salts, while the exported fertilizers were animal refuse and phosphate fertilizers. Of the total expenditure for fertilizers in 1899 70 per cent was consumed in the North Atlantic and South Atlantic States lying within 300 miles of the Atlantic seaboard. Nearly one half of the remainder was purchased in four States, Ohio, Indiana, Alabama, and Louisiana.

As is naturally to be expected, the first settled and longest cultivated portion of the country is that using the greatest quantity of fertilizers. This region lies nearest to the large centres of population and hence of consumption; it produces crops of greatest acre value; and it is so situated that the distances which it is necessary to transport fertilizers are generally less than they would be for the non-fertilizer-using portion of the country. It is true in the United States, as it is in Europe, that a large consumption of fertilizers goes hand in hand with a highly developed and intensive system of agriculture.

T. Lyttleton Lyon,
Prof. of Agriculture, University of Nebraska.

Fesch, Joseph, zhō-zef fesh, French ecclesiastic: b. Ajaccio, Corsica, 3 Jan. 1763; d. Rome 3 May 1839. He was half brother to the mother of Napoleon. After Bonaparte in 1801 concluded the concordat with Pius VII. he became in 1802 archbishop of Lyons, and next year a cardinal. He was likewise appointed French ambassador at Rome, and made himself very acceptable to the Pope by his ultramontane tendencies. On the approach of the Austrians in 1814 he fled with his sister, Madame Bonaparte, to Rome, but Napoleon's return brought him back to France, and he acted as a peer during the Hundred Days. When called upon by the Bourbons to resign his episcopal rights he decidedly refused, but in 1825, after a papal brief interdicted him from exercising spiritual jurisdiction, he renounced the office, but retained the dignity.

Fes'cue, the popular name of a genus of grasses (*Festuca*), numbering upward of 80 species. The genus is of wide geographical distribution, but particularly numerous in the temperate regions, where they are among the most important of the pasture and fodder grasses. About 25 species are found in North America, many of them naturalized from Europe. The red fescue (*Festuca rubra*) serves to bind loose soil, and is also a good hay grass. The tall meadow fescue (*F. elatior*, var. *partensis*) is a fibrous-rooted perennial, growing from two to three feet high in low meadows and pastures, where it forms fresh herbage among the earliest of the cultivated grasses. The sheep's fescue (*F. ovina*) is much smaller. Sheep's fescue exists in many varieties in the northwestern States, especially in the Rocky Mountain region. Some of the varieties attain the height of two or three feet, but for the most part they are rarely more than a foot high, producing a large amount of fine herbage, which is valuable for grazing, especially for sheep. Some of the native varieties are well worthy the attention of the agriculturist. All the forms of *F. ovina* are «bunch-grasses,» and are devoid of the creeping roots, the presence of which distinguishes the red fescue (*F. rubra*) from this species. Sheep's fescue is well adapted for cultivation on light, dry soils, especially those which are shallow and silicious. A tall species is the giant fescue (*F. gigantea*), which occurs in shady woods and similar situations, from Maine to New York, adventive from Europe.

Fes'senden, Reginald Aubrey, American electrician: b. Bolton, Quebec, Canada, 6 Oct. 1866. He was chemist-in-chief in Thomas Edison's laboratory from 1887 to 1890 and the two following years an electrician with the Westinghouse Company of Newark, N. J. He was elected professor of electrical engineering in the Western University of Pennsylvania in 1893. He is the author of many inventions in electrical and chemical engineering and has written numerous scientific papers.

Fessenden, Thomas Green, American author: b. Walpole, N. H., 22 April 1771; d. Boston 11 Nov. 1837. He was graduated from Dartmouth College in 1796. He went to London in 1801, and while there published anonymously a satirical poem, 'Terrible Tractoration' (1803). He returned to the United States; did literary work in New York; went to Boston and founded the 'New England Farmer' (1822). Some of his publications were: 'The American Clerk's Companion' (1815); 'The Ladies' Monitor' (1818); and 'Laws of Patents for New Inventions' (1822).

Fessenden, William Pitt, American statesman: b. Boscawen, N. H., 16 Oct. 1806; d. Portland, Maine, 8 Sept. 1869. He was graduated at Bowdoin College in 1823 and admitted to the bar in 1827. He entered politics and soon acquired a national reputation as a lawyer and a Whig. He was elected to the United States Senate in 1854, and a week after he took his seat made a speech against the Kansas-Nebraska Bill which placed him in the front rank of senatorial orators. During the Civil War he was conspicuous for his efforts to sustain the national credit. He was made secretary of the treasury in 1864, and, having placed it on a firm basis, resigned in 1865 to return to his seat in the Senate.

Festa, Costanzo, cōs-tän'zō fes'tä, Italian composer: b. Rome about 1496; d. there 10 April 1545. He became a member of the pontifical choir 1517, and composed much church music, many madrigals for three voices, motets, and litanies, many of his manuscript scores being still preserved in the archives of the pontifical chapel and the Vatican. His 'Te Deum' is sung at the election of new popes, the appointment of new cardinals, and at the Festival of the Holy Sacrament. It was published in Rome 1596.

Festivals. See FEAST.

Festus, Porcius, por'shius fes'tus, Roman procurator in Palestine about 60–62 A.D. It was he before whom St. Paul was accused by the Jews; but the apostle appealing to the emperor, Festus sent him to Rome.

Festus, Sextus Pompeius, sex'tus pompē'yus fes'tus, Roman grammarian of the 3d or 4th century of our era, author of an abridgment of a work by Verrius Flaccus, called 'De Verborum Significatione,' a kind of dictionary, very valuable for the information it contains about the Latin language. The original work of Festus has been preserved only in imperfect MS., now at Naples, but it is more fully preserved in the abridgment made by Paul Diaconus.

Fet, A., the pseudonym of SCHENSCHIN, AFANASSIJ AFANASJEWITCH (q.v.).

Fetial, or **Fecial,** fē'shial, one of a college of priests in ancient Rome, said to have been instituted by Numa, consisting of 20 members, who presided over all the ceremonies connected with the ratification of peace or the formal declaration of war, including the preliminary demand for satisfaction, as well as the actual denunciation of hostilities. Their chief was termed Pater Patratus. When sent to a distance to conclude a treaty, they carried with them certain sacred herbs called verbenæ, or sagmina, which were gathered on the Capitoline Hill, and which were considered indispensable in their rites.

Fetishism, or **Fetichism,** fē'tish-izm, the worship of material things (fetishes) as the abodes of spirits, or more strictly the belief that the possession of a thing can procure the services of a spirit lodged within it. It is the lowest of the unsystematic forms of worship found among uncivilized tribes, and exists especially among the negroes in Africa, but also among the natives of both Americas, the Polynesians, Australians, and Siberians. The word itself is ultimately due to the Portuguese, the first Europeans to trade on the west coast of Africa, who expressed their conception of the religion of the natives by the Portuguese word *feitiçāo*, «magic.» Comte used it as a term to describe what he believed to be a necessary stage in the development of all religions in which all external bodies, natural, or artificial, are supposed to be animated by souls essentially analogous to our own. Any object may become a fetish, provided it is capable of being appropriated literally or metaphorically by an individual. Such objects are flints, shells, claws, feathers, earth, salt, plants, manufactured articles, anything peculiar or unknown or not understood, trees, streams, rocks, and even certain animals, as the serpents of Whydah. It is enough for an object to be accidentally associated with an event for it to be regarded as the cause and even the author of that event, whence its elevation to the rank of a fetish. Fetishes may be natural or artificial. Artificial fetishes are either public, preserved by priests, or private, purchasable from them usually at a very high price. In some countries kings and princes have large collections of fetishes, and every family has at least one. They are hereditary, and either hung up in the dwellings or worn on the neck or elsewhere, and are even fastened on domestic animals. They are made to resemble the human form, and the public fetishes are sometimes of gold and very large. The worshippers provide their fetishes liberally with food, but if prayers are not granted they frequently maltreat them, throw them away, or beat them to pieces. In connection with fetish worship there are festivals and sacrifices. For the latter the victims are oxen, swine, and other animals; but sometimes, when the royal and priestly power are united in the sacrificer, criminals, prisoners, or persons of the lowest classes of the tribe are immolated. The festivals — among which the Yam and Adai festival with the Ashantees, and the festival in honor of Khimavong, the god or divine messenger, are especially celebrated — are generally attended by excess in drinking, thefts, fights, and gross licentiousness. The priests form a separate society, with hereditary dignity, property, and privileges. They have in particular the right of retaining the slaves who come to them, or, as they call it, present their bodies to the fetish. See De Brosses, 'Du culte des dieux fétiches' (Dijon 1760), through whom the terms fetish and fetishism were introduced into the history of religious worship. It must, however, be observed that the limits of the term fetish have not yet been agreed upon, as some exclude from it the worship of forests, mountains, rivers, etc. In the luck tokens of gamblers and other superstitious persons there is an analogy to the fetish of the savage. See FAMILIAR SPIRIT; WITCHCRAFT.

Fétis, François Joseph, frän-swä zhō-zef fā-tēs, Belgian musical composer: b. Mons, Belgium, 25 March 1784; d. Brussels 26 March 1871. He published: 'Histoire générale de la musique'; 'Biographie universelle des musiciens' (1834–44); etc., and founded and edited the 'Revue Musicale.' His most popular opera was 'La vielle' (1826).

Fetor, fē'tôr, a peculiarly offensive odor, usually considered to be due to some sort of animal putrefaction. Fetor of the breath may be due to sores of the tongue, cheeks, or gums, to necrosis of the teeth or abcess of the teeth cavities, to poisoning of mercury and the sordes of scurvy. Diphtheretic and streptococus inflammations of the throat cause bad odors that closely resemble fetor. Gangrene and abscess of the lungs cause the most persistent and penetrating fetor. In various diseases of the stomach and intestines accompanied by the absorption of products of putrefaction, fetor of the breath is common. Fetor of the feet is due to lack of porosity of their leather covering and to uncleanliness and excessive perspiration. These conditions result in a maceration of the skin and if infection with certain forms of bacteria takes place this macerated skin is apt to be infected with putrefactive bacteria and consequent upon this is more or less fetor. The treatment of the condition consists in cleanliness, improvement of the foot-gear and antiseptic washes.

Fet'terolf, Adam H., American educator: b. Perkiomen, Pa., 24 Nov. 1841. He was educated at Ursinus College; became vice-president of Girard College in Philadelphia in 1880, and president in 1882.

Feuchtwanger, foiнt'vang'-ĕr, **Lewis,** American chemist: b. Furth, Bavaria, 11 Jan. 1805; d. 25 June 1876. He early displayed a fondness for natural science and made that study a specialty at the Jena University. In 1829 he came to New York, where he opened its first German pharmacy. He soon won a reputation as a chemist, mineralogist, and manufacturer of rare chemicals. He was the first to introduce the alloy, German silver. His works are: 'Popular Treatise on Gems' (1838); 'Elements of Mineralogy' (1839); 'Treatise on Fermented Liquors' (1858); 'Practical Treatise on Soluble or Water Glass' (1870).

Feudal System. A fee, feud, or fief is a possession, of which the vassal receives the right of use and enjoyment, of disposition and alienation, on condition of fidelity, that is, of affording assistance or counsel, and avoiding all injurious acts, together with the performance of certain services incident to the tenure, while the feudal lord still retains a paramount right. A fief is distinguished from allodial possessions by the circumstance that it cannot be alienated without the consent of the feudal lord, by the services usually due from the vassal, and by a peculiar kind of inheritance. The system originated among the German tribes, and the nature of feudal property is explained by its origin. Such was the passion of the ancient Germans for war, that in time of peace private feuds took the place of public contention; and in default of these the men of military age spent weeks and months and years in adventures, and made incursions into the territory of the neighboring tribes, or took part in the quarrels of the distant ones. In the expeditions of particular adventurers against the adjacent tribes or the Roman provinces, their booty consisted of garments, arms, furniture, slaves. But when the northern hordes broke into the south, and in the partition of the conquered lands large districts fell into the hands of kings or dukes and their subordinates, they gave certain portions of the territory to their attendants to enjoy the possession for life. These estates were called *beneficia* or fiefs, because they were only lent to their possessors, to revert after their death to the grantor, who immediately gave them to another of his servants. From this custom of the ancient Germans arose the feudal system and feudal service, which is purely German. As the son commonly esteemed it his duty, or was forced by necessity, to devote his arm to the lord in whose service his father had lived, he also received his father's fief; or rather, he was invested with it anew. By the usage of centuries this custom became a right; and to deprive one of his paternal fief, though it was prohibited by no law, seemed an act of injustice. This change took place between the 9th and 11th centuries. A fief rendered vacant by the death of the holder was at once taken possession of by his son, on the sole condition of paying homage to the feudal superior. In the case of ecclesiastical fiefs the right of succession belonged, under the same condition, to those who succeeded the last holders in their ecclesiastical office. The castle-fiefs, so called, were a peculiar kind of military fiefs, the possessor of which was bound to defend the castle belonging to his lord. The vassal who directed the defense was called, in the imperial fortresses, a burgrave. Thus the several orders of vassals formed a system of concentric circles, of which each was under the influence of the next, and all moved around a common centre, the king, as the supreme feudal lord. With military vassals another class arose. From the oldest times in the courts of kings and the governors whom they appointed, as well as in those of the bishops, were certain officers who at first performed active service, but were afterward rather a splendid appendage to the court. The four offices of the marshal, the chamberlain, the cup-bearer, and the sewer, are the oldest and most honorable, but by no means the only ones; offices, on the contrary, were as numerous as the employments which could be devised at court. These officers, at a period when money was scarce and the old German notion in full vigor which considered none but landed proprietors as citizens, and none but the owners of large estates as noblemen, were naturally rewarded by grants of land during the time of service; and these estates, like the military fiefs, but somewhat later, certainly not before the time of Frederick I. (1152–90), became by degrees hereditary. The splendor of the court, and the advantages accruing from these services, induced many noblemen to solicit them. They became the first in the new class of servants or ministers which was thus formed; and under them there was a multitude of other servants, particularly on the estates of the nobility.

A refusal to perform feudal serivce, or any other violation of fealty, was styled felony. Upon this and other difficulties incident to feudal property, as in cases growing out of the succession, surrender, alienation, or under-tenure of a fief, the lord decided in a feudal court, filled by vassals, who were required to be of equal rank with the accused. To appear in these courts at the summons of the lord of the manor, and accept the place of an assessor there, was reckoned among the duties incident to a fief. As the relation of lords and vassals (at that time one of the most important relations in life) became more and more widely spread, and the number of vassals increased at the expense of the ancient immediate subjects of the empire, the latter were thrown into the background, and at length nearly forgotten.

In the 10th and 11th centuries no duty due from subjects was known except feudal duties; the whole German empire was one vast feudal possession, and the ideas of feudal lords and national sovereigns were wholly confounded. If any one was neither a lord nor a vassal he was scarcely looked upon as a citizen. Hence few rich landed proprietors ventured to rely upon their own strength, without a feudal connection. And even most of these at last yielded to the spirit of the age, and became royal vassals. The emperor, likewise, used every means to induce them to adopt such a course.

From the feudal system, the only social organization of the European states in the Middle Ages, a new system of civil rank arose. The inferior nobility, a rank intermediate between the higher nobility (princes) and freemen, owes its origin, it is said, to this institution; and a regular scale of rank was formed among the vassals, without detriment, however, to the principle of equal birth. The king formed the first class; the spiritual princes, bishops, and immediate abbots constituted the second; the lay princes, dukes, landgraves, margraves, and immediate counts, the third; those barons, or rich landed proprietors, who owed fealty to no one, but yet, on account of their limited rights or possessions, were the vassals of the emperor, the fourth; those freemen who stood in the same relation to the princes, the fifth; the vassals of the former and the servants of the princes, the sixth; and the possessors of small fiefs, the seventh. Besides these ranks, after some centuries, the order of citizens was formed, as being included under no one of them. The spirit of the feudal system, grounded on the prevalence of landed property, was necessarily foreign to cities which owed their origin to industry and personal property, and founded thereon a new sort of power. The principles of the feudal laws were developed and established by the Lombard lawyers of the 12th century. The collection of feudal laws and customs which is appended to the Roman code under the title of *Libri Feudorum* became the code of feudal law over a great part of Europe.

The feudal form of government, at a period when a spirit of independence and of opposition to despotism was abroad in the land, was well suited to put into the hands of one governor, as supreme feudal lord, the reins of the national power, to be employed against foreign enemies without endangering domestic freedom. But the purity and influence of feudal relations in time became less; and the strength of the national government declined amidst a spirit of disaffection and sedition, which became universal when nobles began to perceive that the feudal government was not naturally dependent on kings, but kings on it. Indeed, the sovereigns had no other security for their subjection than the feudal oath and the menaces of punishment, which the king might not have the ability to carry into effect, when his power was divided in most of his states, either by investiture or by the usurpations of the princes. Thus the vassals of the crown in Germany, Italy, and the older districts of France succeeded in depriving the king of almost all power, even of the external honors of royalty; and never, in the two first countries, and in France only after the extinction of the great baronial families, could he succeed in establishing a new authority independent of the feudal power. See MIDDLE AGES.

Feuerbach, Ludwig Andreas, lood'viн än'-drā-äs foi'ĕr-bäн, German philosopher: b. Landshut 28 July 1804; d. near Nuremberg 13 Sept. 1872. He was the son of Paul Feuerbach (q.v.). He was a Hegelian and materialist whose opinions hindered a professional career, and who devoted himself to metaphysics in retirement. His masterpiece, 'Das Wesen des Christenthums' (1841) was translated by George Eliot into English as 'The Essence of Christianity.' In his 'Theogonie' (2d ed. 1866), he deals with worship from the historical standpoint. Other works of his are: 'History of Modern Philosophy from Bacon to Spinoza' (1833); 'Criticism of the Philosophy of Leibnitz' (1837); 'Pierre Bayle' (1838); 'Principles of the Philosophy of the Future' (1843); 'The Essence of Religion' (1845). See Lives by Beyer (1873); Grün (1874); Starcke (1885).

Feuerbach, Paul Johann Anselm von, powl yō'hän än'zelm fon, German jurist and criminal law reformer: b. Hainichen, near Jena, 14 Nov. 1775; d. Frankfort-on-Main 29 May 1833. Among his best-known works are: 'Critique of Natural Law' (1796); 'Anti-Hobbes' (1798); 'Lehrbuch des gemeinen in Deutschland geltenden peinlichen Privatrechts' (1801); 'Merkwürdige Kriminalsrechtsfälle' (1808–11); 'Kaspar Hauser: An Instance of a Crime Against a Soul' (1832).

Feuillants, fė-yoṅ, in ecclesiastical history, a religious order clothed in white and going barefoot, who lived under the strict observance of the rule of St. Bernard. The name was occasioned by a reform of the order of Cistercians (1577), first made in the abbey of Feuillens, a Cistercian abbey in Guienne. There were also convents of nuns who followed the same reform, called *Feuillantines.* The first of them was established near Toulouse in 1590. Eleven years later the order transferred its headquarters to Paris, and continued to flourish until suppressed, along with other religious orders, by the Revolution of 1789. The monastery was taken possession of by a club celebrated in the political history of France under the name of the Feuillants, and of which Mirabeau was a member. It was a weak rival of the Jacobin club, and fell before the clamor of a mob in 1791.

Feuillet, Octave, ōk-täv fė-yā, French novelist and dramatist: b. Saint Lô, Manche, 11 Aug. 1812; d. Paris 29 Dec. 1890. Between 1845 and 1858 he gained a good deal of notice with his novels and a series of comedies and tales, some of which were published in the Revue des Deux Mondes. In 1857 the appearance of 'Le Roman d'un Jeune Homme Pauvre' raised Feuillet to the first rank of the novelists of the day, and was immediately dramatized by the author himself. Next followed 'Histoire de Sibylle' (1862), and in the year in which it appeared Feuillet was elected to the French Academy, succeeding to the fauteuil of Scribe. Among his other numerous novels are: 'Monsieur de Camors' (1867); 'Julia de Trécœur' (1872); 'Un Mariage dans le Monde' (1875); 'Le Journal d'une Femme' (1878); 'Histoire d'une Parisienne' (1882); 'La Morte' (1886); 'Le Divorce de Juliette' (1884); 'Honneur d'Artiste' (1890). His works have a refined humor, and are free, especially the earlier, from coarseness. His dramas also met with considerable success, but they are on the whole inferior to his novels. Feuillet's 'Théâtre Complet' appeared in 1892–3. He was succeeded in the Academy by Pierre Loti.

Féval, Paul Henri Corentin, pōl oṅ-rē cō-roṅ-tăṅ fā väl, French novelist: b. Rennes 27 Sept. 1817; d. Paris 8 March 1887. His first story, 'The Seals' Club' (1841), and others, having given him some note, he was offered a large sum to write, under the pseudonym "Francis Trollope" (as though an Englishman), a sensational story 'The Mysteries of London,' after the manner of Sue's 'Mysteries of Paris.' It was done in 11 volumes, was immensely successful, widely translated, and put on the stage. He remained a very fertile, spirited, and popular writer, often dramatized, with long runs. Especially successful were: 'The Son of the Devil' (1847); 'The Hunchback' (1858); 'Mrs. Gil Blas'; 'The Last Man Alive' (1873); 'The Wonders of Mount St. Michael' (1879). At first a Free-thinker, in his later years he became an ardent Catholic.

Fever, a condition in which the temperature of the body is above normal. The average daily range of temperature in men is from 98° to 99° F., and in women from quarter to half a degree higher. In children temporary elevation even as high as 100° F. may occur from conditions of excitement and from over-exercise, but this should not be termed fever. Slight daily variations in temperature are usual. Thus the maximum temperature occurs usually from 5 to 9 P.M. There is then, as a rule, during sleep a decrease until a minimum is reached, some time between 2 and 4 A.M. It is probable that diminished muscular activity and lessened food absorption are responsible for much of this variation. Temperature usually rises during strong muscular exercise, and also after a meal. These slight rises are balanced by heat-loss from increased perspiration. The temperature of man in the tropics and in the Arctic zone does not vary more than 1° C. (For discussion of bearable extremes of heat and cold, heat-production, heat-loss, and the nervous mechanism that controls the general phenomena, see Animal Heat.)

Modern pathology teaches that fever is the index of a reaction of the human body in its struggle with some foreign invader, and is brought about by excessive oxidation and diminished heat-loss. Fever is usually accompanied by an increase in the number of respirations, by an increased number of contractions of the heart, raised pulse-rate, an increase in the blood-tension in the blood vessels, and by other symptoms of general malaise. These are headache, dry mouth, dry skin, and at times increased mental excitement. Fever from this point of view is a conservative process, and is nature's own method of overcoming some form of infection or intoxication Fever as a general process should be distinguished from the many special kinds of so-called fevers that are described. Thus the term fever as used in typhoid fever, scarlet fever, lung fever, etc., is a relic of earlier medical teachings, in which the rise in temperature was considered the essential part of the disease. It is now recognized that fever is only one of the features in the general history of the development of the disease-process. The height of the temperature during fever may vary considerably. If the temperature is not above 100° F. (37.7° C.), it is spoken of as light fever; when between 100° and 103° F. (37.7° and 39.4° C.) it is called moderate fever; between 103° and 105° F. (39.4° and 40.5° C.) it is spoken of as high fever; while above 105° F. (40.5° C.) hyperpyrexia is the term that is applied. Temperatures as high as 110° F. have been recorded in patients who have recovered. The course of most fevers is, for purposes of convenience, divided into (1) the initial stage, which usually starts with chilliness and often with a distinct chill; (2) the hot stage, when the temperature has risen and is at a fairly constant normal, during which the blood vessels at the surface are dilated, the skin is flushed and feels hot and dry; this condition perhaps lasting a few hours, or it may be several weeks, according to the disease-processes that produce it; and (3) the terminal stage. This may be ushered in by a previous perspiration, with sometimes increased urination and prompt subsidence of the temperature; or the temperature may slowly sink to normal by a process of lysis (q.v.). Each type of disease-process manifests its own peculiar temperature-variation, and the study of temperature-curves is extremely important in the determination of the disease.

Fever results not so much from an increase in the heat-production alone, but in a disturbance of the heat-regulation or thermotaxis (q.v.); for it is perhaps true that the amount of heat produced by an athlete in a mile run is vastly greater than that produced throughout the entire four weeks of a severe typhoid fever yet the heat-loss keeps pace in the runner with the heat-production. It is the relation between these two factors that is disturbed in fever. Fever is largely a conservative process, and a moderate degree of temperature is believed to be rather beneficial than harmful. The real danger in fever is not the temperature, unless it is excessively high — from 104° to 105° F. — but it is the poison that is being made in the body, either by perverted metabolism or by bacterial or chemical intoxication. Therefore, in the treatment of disease with rise in temperature the reduction of the fever is not the only point to be attained. During fever there is increased oxidation, increased elimination of uric acid, diminution of most of the secretions, notably the saliva, the gastric juice, the bile and, save in the terminal stages, the sweat. The kidney-secretion is also decreased during the hot stage, because more water is being lost through the skin and lungs than usual. Changes in the blood are constant, and usually consist in an increase in the number of leucocytes, or white blood-cells. High temperatures may produce degeneration in a number of tissues of the human body. The most important ones are those of the nerve-cells. These changes may take place if the temperature gets above 105° F., and even lower temperatures acting for a very long time may cause serious structural changes in the nervous system. The treatment of fever, as has been indicated, should mean the treatment of the disease that is causing the fever, and will be considered under each particular topic of fever. Consult: Hektoen, 'American Text-book of Pathology' (1901); Schäfer, 'Text-book of Physiology' (1900). See MALARIA; RELAPSING FEVER; SCARLET FEVER; TYPHOID FEVER; YELLOW FEVER.

Fever-bush (*Benzoin benzoin*), an American shrub of the laurel family (*Lauraceæ*). It grows from 4 to 20 feet high, in moist woods and along streams from Massachusetts, through Ontario, to Michigan, south to Kansas, and eastward to North Carolina. An infusion of the sweet-smelling bark is used as a tonic in fevers. The bright berries of the tree, ripe in August and September, are sometimes ground and used as spice, for which reason it is locally called spice-bush or wild allspice. It is also known as Benjamin-bush. The name fever-bush is also applied to the *Ilex verticillata.*

Feverwort (*Triosteum perfoliatum*), a perennial of the honeysuckle family (*Caprifoliaceæ*), a native of North America, where its dried and roasted berries have been occasionally used as a substitute for coffee; its roots act as an emetic and mild cathartic. The plant grows in rich soil from Quebec westward to Minnesota, and south to Kansas, Kentucky, and Alabama. It has a number of common names, and is known locally as fever-root, horse-gentian, wood ipecac, tinker's root, wild coffee, etc.

Fewkes, fūks, **Jesse Walter,** American anthropologist: b. Newton, Mass., 14 Nov. 1850. He was graduated from Harvard in 1875, and was for 10 years associated with Alexander Agassiz in the Marine Laboratory at Newport, R. I. Since 1895 he has been connected with the Smithsonian Institution, and has written extensively on professional themes, his papers having usually appeared in the 'Proceedings' of the many scientific societies of which he is a member. He edited the 'Journal of American Ethnology and Archæology' 1891-4.

Feydeau, Ernest Aimé, ĕr-nest ā-mā fā'dō, French novelist: b. Paris 16 March 1821; d. there 29 Oct. 1873. His realistic story 'Fanny' (1858) had an unprecedented success. It was followed by 'Daniel' (1859); 'Catherine d'Overmeire' (1860); 'Sylvie' (1861); and 'A Début at the Opera' (1863). Of his later works one only had any marked success, 'The Countess de Chalis, or the Morals of Our Day' (1868).

Feyen, Eugène, ė-zhen fā-yäṅ, French painter: b. Bey-sur-Seille, Meurthe-et-Moselle, France, 13 Nov. 1815. One of the many successful pupils of Paul Delaroche. He was awarded a second class medal at the Salon in 1880, a third class medal at the Paris Exposition 1889, and the cross of the Legion of Honor in 1881. While he began as a painter of portraits and of the nude, he gradually drifted into genre subjects, which are evidently congenial to his talent, and his pictures of the seaside and the fisher folk are distinguished for clever composition and refreshing color. 'The Harvesters of the Sea' (1872), (in the Luxembourg); 'The Bay of Cancale' (1885); and 'The Sailor's Sweetheart' (1890) are his best works.

Feyer-Perrin, François Nicolas Augustin, fräṅ-swä nĭ-kō-lä ō-güs-täṅ fā-yä pē-räṅ, French painter: b. Bey-sur-Seille, Meurthe-et-Moselle, 1829; d. Paris 14 Oct. 1888. He began his career as an artist in the drawing school at Nancy and subsequently attached himself to the studios of Cogniet and Delaroche at Paris. At first he hesitated in choosing a specialty between subjects of poetic allegory, genre subjects, or varying race type, or historic painting. Since 1864 he has confined himself to painting the scenery and people of the seashore, especially in Brittany. His work has been successful, because it is distinguished by poetic feeling, delicate characterization and transparently brilliant coloring. His most famous pictures are in the Luxembourg, namely, 'The Return from Oyster-fishing' (1874) and 'The Fisher-girls of Cancale at the Spring' (1873).

Fez, fĕz, **Kingdom of,** once independent, but now the most northern section of the empire of Morocco; bounded north by the Mediterranean; east by Algeria; south by the river Om-er-begh or Morbeza, which separates it from Morocco proper; and west by the Atlantic. It was conquered and united to Morocco in 1548. See MOROCCO.

Fez, Morocco, city, capital of the province of Fez; 95 miles from the Atlantic, 225 northeast of Morocco. Fez contains over 100 mosques, one, El Carubin, has a covered place for women who may choose to participate in public prayers, something unusual in Mohammedan places of worship. Good public baths are numerous. Its chief manufactures are leather, red caps (fez), and silk shawls. Twice a year caravans go from Fez across the desert to Timbuktu. Fez has always been considered one of the chief seats of Moslem learning. Old Fez was founded in 793 by Edris II., a descendant of Mohammed, and continued the capital of an independent kingdom till 1548, when it was, together with its territory, conquered and annexed to Morocco. Fez has always been held so sacred by the Arabs and others, that when the pilgrimages to Mecca were interrupted in the 10th century, the western Moslems journeyed to this city, as the eastern did to Mecca; and even now none but the Faithful can enter Fez without express permission from the emperor. Pop. (estimated) 140,000.

Fezandié, fā-zäṅ-di-ā, **Clement,** American educator: b. New York 15 Sept. 1865. He has been scientific instructor in New York schools and has published: 'Through the Earth' (1898); 'Two New Jersey Crusoes' (1901).

Fezzan, fez-zän', Africa, a province in the southern part of the Turkish vilayet of Tripoli; area about 150,200 square miles. In the northern part are low mountains, or hills, one of which, Jebel-es-Sudah, or Black Mountain, is composed largely of basalt. Sandy plains and a few fertile valleys are in the southern part. There are no streams of water and but few natural springs; but good water may be obtained at a depth of from 10 to 12 feet. There are a few small lakes, usually covered with a thin crust of carbonate of soda. Rain seldom falls; in some places years intervene between the short periods of rainfall. Jackals, gazelles, and foxes, the ostrich, vulture, and falcon are found in the hills. The manufactures are coarse linen and cotton goods and some ornamental articles made from gold and silver. Trade with neighboring cities is carried on by means of caravans. Pop. (estimated) 50,000.

Fiacre, fē ä'kėr (Fr. pron. fyä kr), or **Fiachrach, Saint,** French monk; d. about 670. He was of Irish birth and settled near Meaux in France, building a small monastery there. From the 9th to the 17th century was famed as a worker of miracles, especially as curing a kind of tumor. His shrine, ultimately deposited in the cathedral of Meaux, was long an object of pilgrimage. The first livery stable in Paris was established in 1641 by the owner of the Hotel de Saint Fiacre. From the fact that a statue of the saint stood above the door the term fiacre, as the name of a public carriage, is derived.

Fiat, fī'ạt, an order of a judge or of an officer whose authority, to be signified by his signature, is necessary to authenticate particular acts; a short order or warrant of the judge, commanding that something shall be done. See 1 Tidd, Pr. 100, 108. Fiat in bankruptcy, in English law, was an order of the lord chancellor that a commission of bankruptcy should issue. Fiats in bankruptcy are abolished by 12 and 13 Vict. c. 116.

Fibiger, fē'bĭ-gėr, **Johannes Henrik Tauber,** Danish poet and clergyman: b. Nykjöbing 27 Jan. 1821. He wrote dramas founded on biblical history: 'Jephtha's Daughter' (1849); 'Jeremiah' (1850); 'John the Baptist' (1857); also a few secular tragedies, the most notable among them being: 'Cross and Love' (1858) and 'The Everlasting Struggle' (1866), which has been very popular; and a narrative poem in 16 cantos, 'The Gray Friars' (1882).

Fibonacci, Leonardo, lā-ō-nar'dō, fē-bō-nä'chē, called **Leonardo Pisano,** Italian mathematician: b. Pisa about 1180; d. about 1228. Little is known of his life except from his writings, which were collected 1857–62 by Prince Boncompagni and include: 'Liber Abaci' (1202); 'Practical Geometriæ' (1220); 'Liber quadratorum' (1225); 'Flos'; 'A Letter to Theodore.' He traveled in Egypt, Syria, Greece, Sicily, and elsewhere, placing himself wherever he journeyed in communication with the leading mathematicians of the region visited. The 'Series of Fibonacci,' sometimes called the 'Series of Lame,' is as follows: 0, 1, 1, 2, 3, 5, 8, 13, 21, 34 — each term being equal to the sum of the two which precede it, indicated algebraically as $\frac{U}{n+2} = \frac{U}{n+1} + \frac{U}{n}$, and having several other remarkable characteristics important in higher arithmetic.

Fibre. Vegetable fibre is derived from the cellular structure or tissue of plants, the cells of which vary in diameter from one three-hundredth to one five-hundredth of an inch, the smaller sizes admitting of 125,000,000 cells to a cubic inch. The walls of these cells are composed of a starch-like substance called cellulose, enclosing the life principle or germ of the plant, known as protoplasm. There are three forms of cells, simple cells, woody cells, and ducts. Woody fibre is formed by the lengthening and thickening of simple cells. The ducts or vessels are large cylindrical cells whose walls have been absorbed and broken away. Wood cells consist of tubes one or two thousandths of an inch in diameter, their ends pointed and overlapping, so that when detached they form a continuous thread of cell structure or fibre proper, such as a filament of flax; and when they occur in the bark of dicotyledonous plants, or exogens, they are known as *bast* fibre. In monocotyledons, like the palms, and the century plant, the fibrous cells are built up with vessels into a composite structure known as "fibrovascular bundle." These bundles of elongated, thickened cells pressed firmly together, and often embedded in soft cellular tissue, so to speak, the bones or structural part of the plant, are called *structural* fibres, sisal hemp being an example. Even the common or simple cells form a valuable fibre material when they are produced on the surfaces of the leaves, stems and seeds of plants, in the form of hairs. This form of fibrous substance is known as *surface* fibre, cotton being an example. In this instance the hairs envelop the seeds produced in the boll or capsule. The "down" on the stems and surfaces of the leaves of plants is another example.

The term fibre is also given to other forms of vegetable growth where the fibrous material is not employed in the form of detached filaments, like flax sisal and cotton. The stems and twigs, and even wood of exogenous trees, divided into splints, and used for basket-making are recognized as fibre; and in like manner the stems and leaves of endogenous plants split or used entire, as rattan, or when coarsely subdivided for plaiting into such articles as hats, mats, etc., are also classed as fibre. The stripped epidermis of palm leaves, such as the raffia of commerce, is considered fibre, yet it is not in any sense filamentous. Even some species of mosses, marine weeds and fungous growths, on account of their economic employment are regarded as fibre substitutes, and are mentioned in the category of fibres. In general terms, however, "fibre" is composed of bundles of bast or fibrovascular tissue in the form of long flexible filaments, such as flax, hemp or manila; or of hairs, such as cotton, capable of being twisted or spun into yarns or threads, to be manufactured into fabrics or cordage.

The following classification illustrates the different forms of fibrous material recognized by experts, and shows the positions of the different fibres in their relations to each other:

All fibrous material is classed in two grand divisions: A, Fibrovascular structure and, B, simple cellular structure. A is again divided into three groups: (1) Bast fibres; (2) Woody fibres, and (3) Structural fibres; B is divided into two groups, (4) Surface fibres, and (5) Pseudo-fibres or false fibrous material.

1. The bast fibres are derived from the inner fibrous bark of dicotyledonous plants, and are composed of bast cells, their ends overlapping to form in mass a continuous filament. Their utility is to give strength and flexibility to the tissue.

2. Woody fibres may be: (a) the stems and twigs of exogenous plants, or (b) the roots of exogenous plants entire, or subdivided into withes for use in basketry or a rough kind of cordage, or for coarse thread for stitching and binding (as in canoe manufacture); or (c) the wood of exogenous trees reduced to layers or splints, for baskets, or for excelsior; or (d) the wood of certain exogenous trees reduced to pulp for paper.

3. Structural fibres are derived (a) from the structural system of the stalks, leaf stems and leaves of monocotyledonous plants (as the agaves and palms) occurring as isolated fibrovascular bundles, surrounded by a pithy, spongy, corky, or often soft cellular mass, covered with a thick epidermis. They give the plants rigidity and also serve as water vessels; or (b) the entire stems or leaves of the same plants, simply split or shredded (such as straw plait); or (c) the fibrous portions of the leaves or fruits of certain exogenous plants when deprived of their epidermis and soft cellular tissue (the vegetable wool from pine needles).

Under division B, simple cellular structure, the (4) Surface fibres are recognized as (a) the hairs surrounding the seeds or seed envelopes of exogenous plants, and usually contained in a pod or capsule (as cotton); (b) hair-like growths, or tomentum, produced on the surfaces of stems, leaves, or leaf-buds of plants (as pulu); or (c) fibrous material produced in the form of epidermal strips from the endogens (as raffia). The (5) Pseudo-fibres, strictly speaking are not fibres, but false fibrous material employed as substitutes for the true fibres. These are: (a) certain mosses, used as packing substances; (b) certain leaves and marine weeds, also used for packing; (c) seaweeds wrought into fish-lines or cordage, and (d) fungus growths employed in some of the economic uses to which true fibres are put.

A review of the uses of fibres in the arts, by man, shows seven general classes of economic employment, each of which may be subdivided, further, to illustrate special utility.

1. *The Spinning Fibres* enter into the highest forms of manufacture, such as the production of cloth and woven or netted fabrics, and they also include the cordage fibres. Among spinning fibres those for the production of fabrics naturally are the most important commercially. The fibres of the first rank, which enter into fine and coarse textures for wearing apparel, house furnishings, awnings, sails, etc., are chiefly cotton, flax, hemp, ramie, pineapple fibre, and the finer manila hemps; those of the second rank, jute, cocoanut fibre and some of the Agaves find use in burlap or gunny, webbing, rough sacks, coarse floor coverings, etc. The netting fibres, also included in the spinning fibres, are derived from a very much wider range of plants, many of which are not in cultivation. Besides cotton, flax and ramie, employed chiefly in laces and knit goods, nets, etc., there are scores of tree basts, Agave, palm and grass fibres, which find use, both commercial and native, in the manufacture of all kinds of nets, hammocks and similar articles. A third group of the spinning fibres comprises those employed in cordage manufacture. They include all of the fabric fibres mentioned above, the so-called hard fibres, Manila and sisal hemps, coir, etc., as well as Sunn hemp, Mauritius, the bow-string hemps, New Zealand flax, Tampico, and many forms of fibre used in the hand manufacture of rope, by natives, in their rude domestic economy.

2. *Tie Material.*— The fibres employed as tie material are legion; many of them can scarcely be called commercial forms as they are largely used by the natives in the countries where they are produced. The tie material is usually the peeled bark of trees rich in bast, stripped or shredded palm leaves, the tougher grasses, and even twigs and roots used with no special preparation, but merely twisted when green, or freshly cut, into rough cordage for the building of huts, enclosures, and even for constructing rope suspension bridges. Raffia, used

FIBRE PLANTS — I.

1. Sisal Hemp.
2. Istle or Tampico Hemp.
3. Cocoanut Plant.
4. Mauritius Hemp.

by nurserymen as a ready-to-hand tying material, is an example.

3. *Natural Textures.*— These are the nature-woven fabrics of tropical countries, which are used as substitutes for cloth, and which are prepared by simply stripping from the plant, in sheets or layers of fibrous substances, and beating. The famous Tappa cloth of the Pacific Islands is an example. Others are the lace barks, the satin-like Cuba bast, employed in ladies' hats, the ribbon-like bast used for cigar wrappers, etc.; also the fibrous sheaths from the bases of the leaf-stalks of palms. The separated and hand-twisted filaments of many of these cloth substitutes are also used for rough cordage.

4. *The Brush Fibres.*—These include such commercial forms as Tampico, Palmetto, Palmyra, Kitool, Monkey Bass, Piassaba, and cocoa fibre, employed in the manufacture of brushes, and as substitutes for animal bristles, as well as the coarser forms, such as broom-corn, broom-root and even twigs and splints as employed in street-sweeping machines.

5. *The Plaiting and Rough Weaving Fibres.*— This is another large group, which includes a wide range of uses not commercial, yet of greatest importance to the natives of the countries where they grow. They are employed in articles of attire and ornament and for use in the domestic economy. The most important commercially are the straw-plaits from wheat, rye, barley and rice straw (the Tuscan and Japanese braids). Other forms are split from palm leaves, such as *Carludovica palmata,* used in weaving Panama hats; plaits are also produced from various fibrous substances used entire, as the tree basts, and even thin shavings of close-grained woods — the «chip» in millinery trimmings. This group also includes the commercial matting fibres produced from grasses and sedges, as well as thatch materials of every description. The basketry fibres are likewise classed in this group, and they are legion, for they include not only the entire range of palm fibres, the grasses, reeds and rushes, yucca fibre, the leaf stems of ferns, etc., but osier and splints from the common woods, pine, ash, hickory and others. Then there are many miscellaneous uses, such as for «willow ware» furniture, chair seats, screen panels, etc., employing bamboo, osier, rattan, rushes, and splints.

6. *The Filling Fibres* are of less importance than any of the preceding, though altogether they form a large group, and include some valuable commercial forms. Their most common employment is in upholstery; wadding, from cotton; feather substitutes for filling pillows and cushions, as the silk cottons («vegetable silk»), «downs,» kapok, and fibrous material from the surfaces of leaves and stems of plants or from their capsules or fruit; mattress and furniture filling, as tow or waste of the spinning fibres (flax, etc.), unprepared basts, straw and grasses; the curled hair substitutes or Spanish moss, Crin végétal, corn husks and others. Oakum for caulking ships, the leaves of reeds or flags used for filling the seams in casks, as well as the fibres used for stiffening mortar, or the staff used in exposition buildings, are included in this category, palmetto fibre and New Zealand flax being examples. Many fibres and fibrous substances are used as packing material, but they need not be enumerated.

7. *Paper Materials.*— This group of fibres might include the whole category of fibrous substances, for there is scarcely a fibre that cannot be made into paper, the expense of preparation being the main question in determining its availability. The *Textile papers* employ the spinning fibres, in the raw state, in the form of waste, tow, jute butts, old manila rope, cotton and linen rags, etc. The *Bast papers* include such eastern fibres as Japanese paper mulberry, the tree basts, etc. The *Palm papers* are made from palmetto, yucca, and many of the tropical palms. The *Bamboo* and *Grass papers* include bamboo, esparto and other grasses, straw and maize; and lastly, the *Wood pulp papers* are made from the cellulose, chemically prepared, from spruce and other native woods.

The employment of fibre in the domestic economy must go back to the most primitive times, for among the uncivilized races of man the world over we find a dependence upon fibre plants for utensils, cordage, clothing, the building and furnishing of their huts, second only in importance to their dependence upon edible plants for food. And these plants supply hundreds of fibres which the inventive genius of the age cannot afford to use commercially. So we have two great groups of fibres, economically speaking. The «native» forms used to supply the common wants of the people of the countries where they grow, and the fibres recognized as commercial forms because they have been found best adapted to certain uses in the industrial world, and have a stated market value. Some of these have come down to us from remote ages, and the larger number long ago established their places because they were proved to be the best for the purposes for which employed, a veritable survival of the fittest. The discovery of many new fibres therefore is hardly a possibility, although we may discover new uses for well-known forms hitherto not largely employed for any purpose. But even such fibres will scarcely find a place among the fibres of first rank, but must fill the places of the better and fully recognized commercial forms as substitutes, and therefore are worth less money.

While the «native» or emergency fibres, that are known, make a list of upward of 1,500 species, the commercial fibres of value to the world would hardly reach two score in number, and those that interest the United States scarcely half that number. Altogether, counting the more unimportant forms, 25 to 30 species may be enumerated, the larger number of which figure as imported kinds, although they are imported in such small quantities, and at such irregular intervals that they cut a small figure indeed. Eight species of imported fibres would include all of the really important kinds representing the material of the great textile industries. They are: Cotton, flax, hemp, jute, manila hemp, sisal hemp, Tampico and coir or cocoanut fibre. The fibres of lesser importance are: China grass or ramie, raffia, Mauritius, Sunn, New Zealand flax, a few of the Mexican Agaves and Yuccas, Piassaba or Brazilian bass, broom root, Esparto, Crin végétal, rattan and vegetable sponge. Straw plait (and its manufactures) are also imported in considerable quantities, and there is some bamboo, kittool and palmyra.

Of native fibres, commercially employed, we use in manufacture slough grass, Spanish moss, two species of Florida palmetto, and the woods of several species of forest trees in basketry and wood pulp, besides straw and maize husks. Many native fibres are used by the North American Indian tribes, but as these are in no way commercial they are not included here. While the fibres of lesser importance are briefly referred to in this article, the references to the more important textile forms will be found alphabetically arranged under their common names, as cotton, flax, hemp, etc. Among spinning fibres of lesser importance are ramie, or China grass, Mauritius and Sunn hemps, and New Zealand flax.

Sunn hemp, *Crotalaria juncea,* is a leguminous shrub which abounds in India and Australia. Synonyms: Conkanee hemp, Indian hemp, Brown hemp and Madras hemp. A bast fibre which takes the place of jute in portions of India, though it is lighter in color and a better fibre, with a tensile strength which adapts it for cordage; used for rope making in this country, present importation less than 300 tons. In India is used for cordage, nets, sackcloth, twine and paper, 50,000 acres having been cultivated in northern provinces in a single year.

Mauritius hemp, *Furcræa gigantea,* is imported from Africa, as its name applies; thrives in the West Indies and Central and South America. Introduced into India, Ceylon and Australia. The plant is closely allied to the Agaves (such as the sisal hemp plant), the fibre being derived from the leaves, which are 4 to 7 feet long and 4 to 6 inches wide. A structural fibre, it is very similar to sisal hemp, and is used for the same purposes. The commercial supply is derived only from St. Helena and Mauritius, where the plant is cultivated. In Venezuela the native supply of this fibre is made into bags, halters, horse blankets, fish nets and cordage, and is known as *fique.*

New Zealand Flax, *Phormium tenax.* A structural fibre derived from the leaves of a liliaceous plant, resembling the flag, native to New Zealand, but found in other portions of Australia. Distributed to the Azores, St. Helena, Algiers, Southern France, and the British Isles. Thrives in California, where its leaves are used as tie material. Its many varieties produced in New Zealand yield fibre capable of manufacture into cloth of the texture of linen, satchels, table mats, sandals, sacks, rugs, and mattings, threads and twines of superior strength, cordage and cables. An inferior grade has been imported into the United States for the manufacture of binding twine. The staff used in the construction of exposition buildings is stiffened with a low grade of this fibre. At the present time 3,000 to 4,000 tons of the fibre is being imported annually, worth from $112 to $128 per ton.

Broom Root, *Epicampes macrura.* Also known as Mexican whisk and *Raiz de Zacaton.* A fibre of a bright yellow color, wavy as though crimped, stiff and harsh, measuring from 10 to 15 inches in length. Is a substitute for Venetian whisk and is used in this country for clothing and velvet brushes, scrub and other household brushes, brooms, etc. The fibre is simply the cleaned roots of a grass which abounds in a wild state in Southern Mexico. We imported last year about 450 tons, worth $85,000.

Piassaba. Two species are represented in the commercial product, the Para fibre, *Leopoldina piassaba,* also known as monkey bass, and *Attalea funifera,* both derived from Brazilian palms. An African species, *Raphia vinifera,* known as West African bass, has been imported to a slight extent in late years. The Bass fibres, from these three species, are stiff and wiry, bright chocolate in color, and are used for very stiff household brushes and brooms, and for street-sweeping machines. The fibre is obtained from the dilated bases of the leaf stalks, which separate into a long coarse fringe; this is collected by the natives, sorted and tied in bundles, and baled for market.

Palmyra, *Borassus flabellifer,* is a similar palm fibre from Ceylon, a little finer, redder in color, and about two feet long. It is obtained from the base of the petioles or leafstalks. It is also found in India, and tropical West Africa; used as a brush material; first came into notice in 1891. Trade name, Cassine.

Kittool, a similar fibre, derived from the jaggery palm, *Caryata urens.* Structural fibre; brownish black, the filaments straight, smooth and glossy, showing considerable tenacity, and capable of twisting as the fibre is elastic. Common in India and Ceylon. We have imported as high as $16,000 worth of kittool in a single year for the manufacture of brushes for brewers use. The fibre is taken from the bases of the leafstalks. For further information concerning this and other fibres briefly mentioned see 'A Descriptive Catalogue of Useful Fibre Plants of the World,' and 'Dictionary of the Economic Products of India.'

Palmetto fibre. Two species of the Florida palmetto supply commercial brush fibre. The fibre from the saw palmetto, *Serrenoa serrulata,* is derived from the macerated stems of the leaves, which are sometimes five feet long. It is a harsh, brittle fibre, white in color when well prepared, and makes a very cheap substitute for bristle brushes. Also used as a substitute for cow's hair in plaster, while the shredded leaves have been employed as mattress filling. The cabbage palmetto, *Sabal palmetto,* yields fibre reddish in color, somewhat resembling cocoa fibre. It is derived from the «boots» or spathes of the leaf-stems which surround the bud or «cabbage,» and in securing the bud the tree is killed. After a process of steaming and crushing the boots, the mass is combed and the softer, tangled fibre extracted, leaving the stiff, straight, coarse brush material, which represents about 25 per cent of the original fibrous substance of a boot. This product goes into cheap brushes for household use.

Crin végétal, or African fibre, *Chamærops humilis,* is derived from an Algerian species of palm similar to the Florida palmetto. The commercial product is produced by shredding the leaves, and as imported resembles twisted ropes of hay. It comes in two colors, a pale greenish (called white) and in black. The twisting crinkles the fibre so that when again opened it retains the «curl,» and in this form is employed as a substitute for curled hair in the filling of mattresses. As the fibre is quite elastic it is a valuable upholstery material.

Spanish moss, *Tillandsia usenoides.* This is a native filling fibre. The plant is parasitic on trees and is seen hanging in dense gray masses

2. Sunn Hemp.
3. Louisiana Jute.
4. China Grass, or Ramie.
5. Cabbage Palmetto.
6. Sponge Cucumber.

in many portions of tropical and sub-tropical America. The fibre is the entire plant in mass, after the gray epidermis has been removed. It is black in color, and resembles curled hair, for which it is a tolerable substitute. Manufactured chiefly in Charleston, S. C., and in New Orleans, La.

Pulu, an Hawaiian surface fibre, useful for stuffing pillows, etc., is simply the hairs which grow at the bases of the leafstalks of several species of *Cibotium,* a genus of tree ferns. It is regularly exported from Honolulu to San Francisco. The substance is yellowish in color, and resembles wool. The golden moss of the Chinese is a similar fibre.

Raffia, *Raphia ruffia,* is a palm fibre, imported from Madagascar. The commercial product comes in the form of narrow ribbons of fibrous material, derived from the cuticle of the leaves of an African palm, taken before they are fully expanded, by peeling the leaf on both sides. Imported as a tie material for nurserymen; used also for the manufacture and trimming of ladies' hats; has recently come into extensive use in connection with splints of rattan, for hand-made fancy baskets, the art now being taught in all of our larger cities. Takes dye readily, and can be purchased in several colors.

Another millinery trimming fibre is the Cuba bast, *Hibiscus elatus,* which comes in the form of thin ribbons of bast, which are the separated layers of the inner bark of a large tree. These ribbons or strips are plaited into ladies' hats, either in the flat, or twisted forms, the white color and satiny sheen making the product peculiarly adaptable to the purpose. In this connection may be mentioned the poplar and willow shavings, or thin strips of wood known as "chip," and imported from Germany for the same purposes.

Straw is imported from Italy, Germany and Japan, wrought into "straw plait" or "braids" for the manufacture of hats, fancy baskets, etc. The Tuscan braids are the finest and are produced from wheat straw specially grown, although rye straw is also employed in Italy. The braids from China and Japan are from rice and barley straw, while the Bohemian straw plait is from wheat. Two native American grasses, *Poa pratensis,* and *Sporobolus indicus,* have also, in past time, been employed for the same purpose.

The Eastern or Oriental floor mattings imported into this country are made from several species of rushes or sedges. The Chinese and Korean are produced from *Cyperus tegetiformis;* the Japanese from *Cyperus unitans,* and *Juncus effusus;* the Indian from *C. corymbosus, C. esculentus,* and *C. tegetum.* Other species are also employed, though the above are the most common. The Japanese mat rush industry is very extensive, over $400,000 worth of mats having been exported in a single year. *Cyperus unitans* is the *Shichito-i* of Japan, from which the cheaper, coarser mats, for the common people, are produced, while *Juncus effusus* is the *Bingo-i,* or form employed for the mats of the higher classes, both being cultivated. The technique of mat making is practically the same in China, Japan, India, and Ceylon. The culms are either used entire or split into two or more parts, and woven upon a warp of thread, these often stretched upon the floor, for much of this material is woven by laborious hand methods.

In the United States a new form of floor matting has recently come into vogue, produced from slough grass, *Carex filiformis,* also known as the slender sedge. The material grows wild over vast areas of the river bottoms of the Mississippi, and streams tributary. It is cut in July or August, dried, and by means of special machinery, worked into a continuous strand, bound with thread or fine twine. It is afterward woven into mattings, the warp being cotton yarns in high colors. The grass twine as prepared for weaving is also used as binder twine for grain.

The sponge cucumber or snake gourd, *Luffa cylindrica,* is imported from Japan in considerable quantities as a substitute for the bath sponge. The commercial article is the entire gourd with the epidermis and seeds removed, presenting the appearance of a network of straw-colored fibre. It is extensively cultivated in Japan, for export. Grows in the southern United States, but has never been produced commercially, though used for bath sponge, flesh brush, dish cloths, and even for fancy baskets, and bonnet crowns.

Among high-grade fibres that have been the subject of experiment in the United States, but which are not produced commercially may be mentioned pineapple fibre, from *Ananasa sativa.* Fibre extracted in Florida was found to be fine, soft, flexible and very resistant. The filaments yield to treatment in the alkaline bath and are easily subdivided, producing an admirable spinning fibre. In the Philippines, the fibre is used to some extent in the fabric known as piña cloth, which is becoming known in Europe and America, and may in time become of commercial importance. See Special Report No. 5, Office of Fibre Investigations, Department of Agriculture, Washington, and Bulletin No. 4, Philippine Bureau of Agriculture, Manila, for further information regarding pineapple fibre.

Another valuable but unemployed spinning fibre that might be produced in the United States is the bowstring hemp, *Sansevieriasps.* The plant grows to perfection in southern Florida, and yields a fibre which combines all the good qualities of length, strength, fineness, color and divisibility, which adapts it for employment in the manufacture of fine threads, and even fabrics. The lack of machinery to properly extract the fibre, as well as the fibre of pineapple, is the chief drawback to the establishment of two new industries. There are eight or more species of bowstring hemps, all of which are considered valuable for fibre. The Florida species is *S. longiflora.*

Mexico abounds in fibre plants, many species of Agave and Yucca not recognized as standard commercial forms being employed for rope, coarse bags and mattings. A little of this fibre finds its way to the United States for employment in coarse twine manufacture, though not in appreciable quantities at present. Palma Istle, and Pita Sylvestre are local trade names applied to a harsh, low-grade fibre produced from two species of Yucca. Pita is a Mexican name applied to several Agave fibres, and to some allied species, though pita is generally understood to mean the fibre of *Agave americana.* There are several species of Agave, known in Mexico as Mescals, which produce fibre of good strength, which might be employed in cheaper grades of cordage.

The imports of commercial fibres for the year ending 30 June 1902 amounted to a value of over $30,000,000, though this sum should not be taken as alone representing the consumption of fibre manufactures in the United States, for we import vast quantities in the manufactured form. As an illustration, the importation of flax manufactures in a single year has been seven times greater than the imports of raw and hackled flax for the same period. Probably the ratio of raw to manufactured, as shown by the tables of importation, would stand about one to four, for all classes of fibre, which with the native kinds, not considering paper materials, might give a grand total of upwards of $125,000,000, as the value of the raw and manufactured for a single year. See COIR; CORDAGE; CORDAGE INDUSTRIES; COTTON; FLAX; HEMP; ISTLE; JUTE; MANILA HEMP; MATTING; RAMIE; SISAL HEMP.

CHARLES RICHARDS DODGE,
Commercial Fibre Expert, Washington, D. C.

Fibre Plants. See ESPARTO; FIBRE; FLAX; JUTE; RAMIE; SISAL; etc.

Fibrin, fī'brin, the chief substance formed in the coagulation of the blood-plasma. It may also be found in coagulation of lymph and in other fluids that contain fibrinogen. It is usually taken from the blood by whipping it with a bunch of wire or glass rods as it falls into a vessel, before it has had time to coagulate into a solid mass. When obtained from fresh blood in this way, fibrin is a stringy substance while wet, and dries to a glue-like mass. It is a proteid, and consists of at least two globulins, one coagulating at 50° C., the other at 56° C. Under the action of pepsin these are converted into acid albumin, proteoses, and peptones. Blood yields from .2 to 4 per cent of its weight of dry fibrin. See BLOOD; FIBRINOGEN.

Fibrinogen, fī'bri-nō-jen, a substance found in the plasma of the blood, and which brings about spontaneous coagulation of that fluid. It is also found in the lymph and in a number of other fluids of the body. Fibrinogen may be precipitated from the blood-plasma by the addition of magnesium sulphate or sodium chloride. It is soluble in dilute alkalies, and is precipitated from solutions in these weak alkalies by acetic acid. Fibrinogen is probably not a simple substance, but a mixture existing in loose combination of at least three substances. These as given by Schäfer are fibrinogen proper, coagulating at 56° C., a globulin, described by Hammarsten, and termed fibrino-globulin, and a nucleoproteid. The relationships of fibrinogen and fibrin and the blood-ferment are expressed by Schäfer as follows: «(1) That the coagulation of blood, that is, the transformation of fibrinogen into fibrin, requires for its consummation the interaction of a nucleoproteid (prothrombin) and soluble lime salts, and the consequent production of a ferment (thrombin); (2) that either nucleoproteid is not present in appreciable amount in the plasma of circulating blood, or that the interaction in question is prevented from occurring within the blood vessels by some means at present not understood; (3) that the nucleoproteid (prothrombin) appears, and the interaction occurs, as soon as the blood is drawn and is allowed to come into contact with a foreign surface, the source of the nucleoproteid being in all probability mainly the leucocytes (and blood-platelets?); (4) that, under certain circumstances and conditions, either the nucleoproteid does not appear in the plasma of drawn blood, or it appears, but the interaction between it and the lime salts is prevented or delayed; (5) that the nucleoproteid (prothrombin) appears in the plasma of circulating blood under certain conditions, being in all probability shed from the red blood-corpuscles; and that when shed out under these conditions from the corpuscles, or when artificially injected into the vessels, it tends to interact with the lime-salts of the plasma and to form fibrin ferment (thrombin), intravascular coagulation being the result; (6) that, under other conditions, either the shedding out of nucleoproteid from the corpuscles, or its interaction with the lime-salts of the plasma, may be altogether prevented and the blood rendered incoagulable, unless nucleoproteid be artificially added, or unless a modification of the conditions is introduced which will permit of the interaction of the nucleoproteid with lime to form ferment; (7) that the nucleoproteid (prothrombin) is incompetent, in the entire absence of lime-salts to promote the transformation of fibrinogen into fibrin; but, as a result of its interaction with lime-salts, it becomes transformed into a ferment (thrombin), which, under suitable conditions of temperature and the like, produces fibrin; (8) that either the place of nucleoproteid in coagulation may be taken by certain albumoses, such as those found in snake-venom, and by certain artificial colloidal substances, such as those prepared by Grimaux, or that such substances may act by setting free nucleoproteid from the leucocytes and other elements in the blood or from the cells of the blood vessels, and thus indirectly promote coagulation.» See BLOOD; COAGULATION; FIBRIN.

Fichel, Eugène, ė-zhen fē-shel, French painter: b. Paris 30 Aug. 1826; d. there 1 Feb. 1895. He was a pupil of Delaroche, but painted very much more under the inspiration of Meissonier, whose exquisite handling is recalled in numerous small canvases of his which by their refined technique and vivid action recall the characteristic intensity and directness of composition which belong to the painter of 'Friedland.' The principal works of this painter are of a high order of genre, and include, 'The Violin Player'; 'A Festival in the Year 1776'; 'The Capture of a Spy'; 'The Wandering Singers'; and the following historic pictures, which have the freedom and imagination of pure genre: 'The Night of August 24, 1572'; 'Founding of the French Academy.'

Fichte, Immanuel Hermann von, im-mä'-noo-āl hār'män fon fĭн'tĕ, German philosopher: b. Jena 18 July 1796; d. Stuttgart 8 Aug. 1879. He was a son of Johann Fichte (q.v.), and in his philosophy was a mystic theist. Among his writings are: 'Speculative Theology' (1847); 'System of Ethics' (1850); and 'The

JOHANN GOTTLIEB FICHTE.

Soul Question: A Philosophic Confession' (1859).

Fichte, Johann Gottlieb, yō'hän gōt'lēb, German philosopher: b. Rammenau, near Bischofswerda, Upper Lusatia, 19 May 1762; d. Berlin 27 Jan. 1814. He studied at Jena, Leipsic, and Wittenberg, passed several years as a private tutor in Switzerland and Prussia, and in Königsberg enjoyed the society of Kant. His 'Versuch einer Kritik aller Offenbarung' (Essay toward a Criticism of all Revelation) (1792) attracted general attention, and procured him the professorship of philosophy in Jena in 1793. In 1800 he was one of the most prominent professors of that university during its most brilliant period. Here he published, under the name of 'Wissenschaftslehre' (Theory of Science), a philosophical system, founded at first on the system of Kant, from which, however, he gradually deviated. On account of an article, 'Ueber den Grund unseres Glaubens an eine Göttliche Weltregierung' (On the Reasons of our Belief in a Divine Government of the Universe), which appeared in his 'Philosophisches Journal' in 1798, he fell under the suspicion of atheistical views. This gave rise to an inquiry, and Fichte resigned his professorship. In 1805 he was appointed professor of philosophy at Erlangen, and in 1810, on the establishment of the university of Berlin, was appointed professor of philosophy there. Fichte's philosophy, though there are two distinct periods to be distinguished in it, is a consistent idealism, representing all that the individual perceives without himself, or, rather, all that is distinguished from the individual, the *ego*, as a creation of this *I* or *ego*. His 'Ueber den Begriff der Wissenschaftslehre' (1794); 'Die Wissenschaftslehre in ihrem allgemeinen Umrisse' (1810); and the 'Anweisung zum seligen Leben' (1806) contain the substance of his teaching. His practical is purer than his theoretical system. His idealism led him to represent the life of the mind as the only real life, and everything else as a mere delusion, and to believe in an almost absolute omnipotence of the will. To excite his pupils to the highest virtue and self-denial was his constant aim as a teacher, and his influence was great, not merely through his power of expression and the originality of his ideas, but through the conviction with which he inspired his hearers of his full belief in, and entire devotion to, his principles. His heart was open to every noble and good feeling. Unshaken integrity, constant friendship, devoted love of what he conceived to be true and good, were his characteristic traits. When Germany was suffering under the wounds of war he, like his countrymen in general, considered Napoleon as the source of the whole distress of his country, and in his 'Reden an die deutsche Nation' (Addresses to the German Nation), published in Berlin while it was still in the hands of the French, he boldly called upon his countrymen to rise and throw off the foreign yoke. The more popular works of Fichte, known in English through the translations of W. Smith, consist of: 'The Vocation of the Scholar'; 'The Nature of the Scholar'; 'The Destination of Man'; 'The Characteristics of the Present Age'; and 'The Way toward the Blessed Life.' His complete works were edited by his son in 8 volumes (1845–6).

Fichtelgebirge, fiн'tel-gĕ-bĕr'gĕ, a mountain range, chiefly situated in the northeast of Bavaria, once covered with pines (*Fichte*, "pine"), and constituting a watershed between the head-feeders of the Elbe, the Rhine, and the Danube. The average elevation of the peaks ranges from 2,700 to 3,200 feet. The highest summits are Schneeberg (3,461 feet) and Ochsenkopf (3,334). In their northern extremities the Fichtelgebirge are connected by intermediate chains, on the one hand with the Erzgebirge, and on the other with the Thuringian Forest. They are composed principally of granite and primitive crystalline slates, with bands and intrusions of gneiss, micaceous slates, basalt, and some strata of the Tertiary Age (*Oligocän*). Snow lies on the summits as a rule from October to May. The chief industries are those connected with mining iron ore, quarrying of marble, manufacturing glass, and getting of timber from the forests. Of recent years the Fichtelgebirge have come much into vogue with tourists. Consult: Ruchdeschel, 'Hand-book of Bavaria.'

Ficino, Marsilio, mar-sē'lē-ō fē-chē'nō, Italian philosopher of the Platonic school: b. Florence 19 Oct. 1433; d. Careggi 1 Oct. 1499. His early display of talent attracted the notice of Cosmo de' Medici, who induced him to translate the writings of Plato and of the Neo-Platonists into Latin; he afterward employed him to aid in establishing a Platonic Academy (about 1460). Ficino engaged in this plan the more readily, because he viewed the Platonic philosophy as a sort of preliminary to, and confirmation of, the Christian faith. In his accounts of this philosophy he did not always make an accurate distinction between Plato and the New Platonists, as appears from his 'Theologia Platonica; de Immortalitate Animorum ac æterna Felicitate,' in which he particularly defends the immortality of the soul against the Aristotelians of his age. Mystic and fanciful views are interwoven with this defense; astrological doctrines, for example, which he afterward rejected. At the age of 40 he was presented by Lorenzo de' Medici with the rectorship of two Florentine churches, and a canonry in the cathedral. His Latin works were first published complete at Basel (1561).

Fick, Adolf, ä dölf fik, German physiologist: b. Cassel 3 Sept. 1829; d. 1901. He was professor at Würzburg and published: 'Die medizinische Physik'; 'Kompendium der Physiologie.'

Fick, August, ow'goost, German philologist: b. Petershagen, Westphalia, 5 May 1833. He studied at Göttingen 1852–7, becoming professor of comparative philology there 1876, and occupying the same chair at Breslau 1888. He is an authority on the primitive Indo-Germanic languages and Greek philology. Among his works are: 'Die ehemalige Spracheinheit der Indogermanen Europas' (1873); 'Vergleichendes Wörterbuch der Indogermanischen Sprachen,' his masterpiece (1874–6); 'Die griechischen Personennamen' (1877); and 'Die homerische Ilias nach ihrer Entstehung betrachtet und in der ursprünglichen Sprachform wiederhergestellt' (1885).

Fiction, in law, is an assumption made for the purposes of justice, though the same fact could not be proved, and may be literally untrue. There are many fictions in the civil law, and a fiction in law is said by civilians to be the assumption of an untruth for a truth, in a thing possible to have been done, but which was not done. The declaring that a note or bond made in a foreign country was made in the county where a suit is commenced upon it, is an instance of a very common fiction, adopted on the ground that suits can be brought in the county only on causes of action existing within its limits; and so the practice has been introduced of declaring that the contract on which an action is brought was made in the county, though the fact seems to be entirely immaterial; for transitory actions follow the person, and it is only of such that the fiction is admitted. The fictitious characters of John Doe and Richard Roe for the purposes of various actions are well known. It is a rule that a fiction of law shall work no wrong; and the fictions in use generally come within this rule.

Fiction in America. While the art of fiction writing in America is scarcely more than 100 years old, its genesis may be traced far back into the records of literature. Prior to 1798, when Charles Brockden Brown laid the foundations of his fame with the writing and the publication of 'Wieland,' the art of writing fiction in this country was scarcely known. Novels were published, imported and read, but they were largely the work of English writers or translations from foreign languages. With the advent of Charles Brockden Brown, however, imaginative literature began to gain a foothold, and the literary man to secure a standing in the professional world. Brown has usually been styled the precursor of the American novelist and the founder of American fiction. There had been isolated attempts at fiction writing before his day, but the results were meagre both in quantity and in quality. The list is virtually complete with 'The Pretty Story,' by Francis Hopkinson; 'The Power of Sympathy,' by Mrs. Morton; 'The Foresters,' by Jeremy Belknap; 'Modern Chivalry,' by Hugh Henry Brackenridge; 'The Algerine Captive,' by Royall Tyler (who also holds position as one of the early American dramatists); 'History of a Corporation of Servants,' a satirical romance, by John Witherspoon; 'Female Quixotism: the Romantic Opinions and Extravagant Adventures of Dorcasina Sheldon,' by Mrs. Tabitha Tenny; and 'The Coquette,' by Mrs. Hannah Foster. Of these early novels 'The Foresters,' by Jeremy Belknap, was the most important. The poet Bryant describes it as «a work which sought to embellish our literature with the charms of wit and humor.» Susannah Rowson's 'Charlotte Temple' can scarcely be accounted an American novel, for it was first published in England and its author was of English birth and residence, although she lived for a considerable length of time in this country.

It is a somewhat curious fact that Charles Brockden Brown (q.v.) reveals in his work little of the American character, the American temperament, and the American people. On the other hand, he shows in his own trend of thought and choice of subjects that longing for the mysterious in life which was later to find its fullest expression in Poe and in Hawthorne. He was a student of the mystic and his novels presage the beginnings of modern psychical research. His 'Wieland,' 'Ormond,' 'Arthur Mervyn,' 'Edgar Huntley,' 'Clara Howard,' and 'Jane Talbot' were varied expositions of experiences now classed exclusively as psychical phenomena, although by him they were treated merely from the curious and spiritual points of view. His life ended 22 Feb. 1810, before he had reached the age of 40, and so slow was the growing interest in American fiction that little advancement had been made prior to his death. With the advent of Washington Irving (q.v.) and James Fenimore Cooper (q.v.), the imaginative literature of America proved the force and might of its English heritage. As early as 1809 appeared Irving's 'Knickerbocker History of New York,' which may fairly be classed as a romance if not as a novel. It was Irving's second published work, his first being the volume of reprinted miscellany called 'Salmagundi,' which had appeared the year before. Surrounded by a group of brilliant men, Irving settled down to a life of literary leisure, and in time 'The Sketch Book,' 'Bracebridge Hall,' and 'Tales of a Traveler' took their place in literature. James Kirke Paulding (q.v.), his friend and comrade, shared the honors of the 'Salmagundi' essays with Irving, and in 1813 his 'Diverting History of John Bull and Brother Jonathan' led the way to a continuous flow of volumes in fiction, poetry and essay which did not cease until his death 6 April 1860. 'The Dutchman's Fireside' was his most important novel.

It was not, however, until 1821–2 that the novel of American life written by a typical American author began its vogue. In that year, with the publication of 'The Spy,' the fame of James Fenimore Cooper had its beginning. He had already written 'Precaution' (1820); but that novel was a romance of English society life, and does not form a part of Cooper's most characteristic work. After 'The Spy,' came 'The Pioneers'; 'The Pilot'; 'Lionel Lincoln'; 'The Last of the Mohicans'; 'The Bravo'; 'The Prairie'; and 'The Red Rover'; and for 30 years, until his death 14 Sept. 1851, Cooper was the pre-eminent American novelist who was equally expert in chronicling the life of the Indians and in writing the narratives of perilous adventures by sea. During this period the American novel and the American novelist proved that their position was secure. John Pendleton Kennedy, with his 'Swallow Barn'; 'Rob of the Bowl'; and 'Horseshoe Robinson'; Dr. Robert Montgomery Bird, with his 'Nick of the Woods'; William Ware with his 'Zenobia' and 'Julian'; Herman Melville with his 'Typee'; 'Omoo'; and other remarkable sea stories; William Gilmore Simms, next to Cooper the most voluminous American novelist, with his many revolutionary and border romances; Charles Fenno Hoffman with his many romances of historical and legendary lore; Mrs. Caroline M. Sedgwick with her 'Redwood'; 'Hope Leslie'; and 'The Linwoods'; are among the few names of novel writers who flourished during the period following the advent of James Fenimore Cooper. One name alone — the greatest of them all — has been omitted, but Edgar Allan Poe's (q.v.) work covered so many branches of literature and the man himself is so absolutely one of the world's great writers that he needs no more than passing mention in this review of American fiction. As a master of the short story and as a writer of some of the finest tales known to any language — 'The Murders in the Rue Morgue'; 'The Tell Tale Heart'; 'The Fall of the House of Usher' — Poe's rank is secure. His achievements in other fields are fully outlined in the article in this work devoted especially to him.

Fittingly after Poe comes the name of Nathaniel Hawthorne (q.v.), for it was in 1850, the year following Poe's death, that 'The Scarlet Letter' was published. This was the first if not the only great American novel. There had been nothing like it in American literature, and scarcely anything like it in the world's literature. At the time of its publication, Hawthorne was 45 years of age, he had been writing since boyhood. and his name had been known for 15 years as that of a novelist and short-story writer of peculiar style, extraordinary gifts and sombre tendencies. 'The Scarlet Letter,' however, immediately showed the unique and unapproachable power of his genius, and with 'The House of the Seven Gables' (1851), 'The Blithedale Romance' (1852), and 'The Marble Faun' (1860), which followed, it placed Hawthorne among the greatest of the world's great fiction-writers. During this era of Hawthorne's progress the art of writing fiction was growing apace. In 1852, 'Uncle Tom's Cabin' achieved three things: it made Mrs. Harriet Beecher Stowe (q.v.) a famous woman, it aroused an enormous public sentiment against slavery, and it created a desire for novel reading among hundreds of thousands of people who could not before have been persuaded even to look into a work of fiction. Mrs. Stowe, as was to be expected, never repeated the triumphant success of 'Uncle Tom's Cabin,' although during her long life she wrote many novels. Nathaniel P. Willis, at this time at the height of his unique fame, was turning out volume after volume of fantastic work in poetry, fiction, and essays. George William Curtis' long and versatile career covered both the ante-bellum and the post-bellum periods, his 'Prue and I,' his 'Potiphar Papers,' and his 'Trumps' being simply imaginative wanderings into a form of fiction and social satire somewhat apart from his general literary interests. Susan Warner had in the very year of the publication of 'The Scarlet Letter' gained for herself an extraordinary popularity with 'The Wide, Wide World,' a story still in extensive demand at public libraries, and Mrs. Mary Jane Holmes, Mrs. E. D. E. N. Southworth and Mrs. Ann Sophia Stephens were beginning that long series of sensational novels which, while not a part of literature, deserve record because of the place they hold in the hearts of the reading public and because they have helped to create a reading habit which has led to better things. At this time, too, there appeared the first American historical novelist, Jeremiah Clemens, of Alabama, who wrote and published 'The Rivals' (1859), and other novels. To this period also belongs Rev. J. H. Ingraham, who from writing many lurid, sensational novels, turned in his latter days to sacred history and evolved 'The Prince of the House of David.' In the sixties, Theodore Winthrop, a descendant of an historic family, a brave young soldier and a gifted writer, began a career in letters which was untimely cut short by his death in the Civil War. He was only 33 years of age, but his 'Cecil Dreeme,' his 'John Brent,' and his other stories published after his death gave evidence of the power he might have become in American literature.

As early as 1839, the poet Longfellow (q.v.), returning from a European trip which had filled his receptive brain with Old World fancies and mediæval legends, wrote his 'Hyperion,' a romantic tale, the heroine of which was Miss Frances Appleton, of Boston, whom he married in 1843. Ten years later Longfellow again turned his thoughts to prose romance, producing in 'Kavanagh' a story remarkable more for its psychological elements than for any of those active phases of thought which should characterize a notable work of fiction. His success was so slight, however, and he was so keenly criticised for his venturesomeness in attempting to leap the bounds of his own field of poetry into an untraveled highway, that thereafter he was content to express his romantic feelings wholly in verse. Among the other American poets whose versatility led them to the writing of novels, Oliver Wendell Holmes (q.v.) is the best known. His famous 'Breakfast Table' series is a compound of romance, essay and poesy, and its four volumes of genial miscellany and philosophy will doubtless live long after his two novels — 'Elsie Venner' (1861), and 'The Guardian Angel' (1867) — are forgotten. It was also in the same decade that Bayard Taylor (q.v.) added his first work of fiction to his rapidly lengthening list of works in almost every branch of literature. His novels comprise: 'Hannah Thurston,' 'John Godfrey's Fortunes,' 'The Story of Kennett,' and 'Joseph and His Friend,' all published between 1863 and 1870. Contemporary with Bayard Taylor was J. G. Holland, who wrote 'Seven Oaks,' and John Townsend Trowbridge, whose 'Neighbor Jackwood,' 'Cudjo's Cave,' and 'Coupon Bonds' are prominent in a long series of works largely made up of poetry and juvenile fiction. Trowbridge stands at the head of a long line of writers who have devoted their energies to the production of books for the young, his position among writers for boys being paralleled by Louisa May Alcott with her 'Little Women,' 'Little Men,' and other clever stories for girls. Other voluminous authors of juvenile fiction during the generation following 1860, when the creation of a special form of literature for boys and girls was at its height, were William T. Adams (Oliver Optic), Horatio Alger, Jr., Elijah Kellogg, and Harry Castlemon. They all of them obviously tried to instruct as well as to amuse their youthful readers, a double purpose attained with less success by that pioneer of juvenile authors, Jacob Abbott, whose chief claim upon posterity he owes to the famous 'Rollo' books which have been burlesqued and parodied ever since their career began about the year 1840.

The modern epoch of American fiction begins with the close of the Civil War, and henceforth romance writers and novelists multiplied rapidly. The post-Civil War writers, those whose reputations were established prior to 1880 and after 1865, are meagre in numbers compared with those who became popular during the last 20 years of the 19th century. Of the writers who arose in the latter period, four names naturally come to mind — William Dean Howells, Thomas Bailey Aldrich, Bret Harte and Henry James the younger. Their names are here given in the chronological order of their appearance before the public. Mr. Howells, who through his facility as a writer and his ability to adapt himself to many varied forms of composition — the novel, the essay, the poem and the play — has practically become the most distinguished, if not the greatest American man of letters, began his apprenticeship in the exacting field of journalism. After the publication of 'A Chance Acquaintance' (1874), he turned his attention to the making of realistic novels, and it was not long before he was accepted as the exponent of a distinctive school of American fiction whose chief claim is its dictum that the commonplace and generally ignored facts of life shall form the true province of the novelist. His books written in pursuance of this method followed one another in rapid succession, the most notable of them being: 'A Foregone Conclusion,' 'A Modern Instance,' 'The Rise of Silas Lapham,' 'The Minister's Charge,' 'April Hopes,' and 'A Hazard of New Fortunes.' Although Mr. Howells has been extraordinarily active in all phases of literary work, it is distinctly as a "realistic" novelist that he is now known and will be remembered by posterity. As Mr. Howells is the exploiter of a theory in fiction, so Bret Harte was the discoverer and creator for literary purposes of an undiscovered country, the California of 1849. He was pre-eminently a short story writer, and it needs only a knowledge of 'The Luck of Roaring Camp,' 'Tennessee's Pardner,' of 'M'liss' and a hundred more of his tales to realize how thoroughly his art was restricted and how its very perfection made it impossible for him to succeed with 'Gabriel Conroy,' and the other long novels he attempted. Thomas Bailey Aldrich, singularly enough, became a novel writer through the vogue of a juvenile tale, 'The Story of a Bad Boy,' published in 1869, after serial appearance in a monthly magazine. Mr. Aldrich has published 'Prudence Palfrey,' 'The Stillwater Tragedy,' and many volumes of short stories. Although Henry James, Jr., has resided in England for many years, he still holds his position as an American author of unique style and genius. He makes no bid for popularity, being content to express his own individuality and thought, and to expound his philosophic views of literature and life to a public which is able to understand and appreciate such novels as 'The American,' 'Daisy Miller,' 'The Bostonians,' and 'The Tragic Muse.' Although Edward Everett Hale and Thomas Wentworth Higginson antedate the foregoing writers almost by a score of years, they practically belong to the same literary epoch, for it is since the Civil War that they have contributed liberally to the supply of American fiction, mainly in the form of short stories. For 20 years or more E. P. Roe's name was held high in the esteem of a large class of fiction readers who delighted in the placid commonplaces of 'The Opening of a Chestnut Burr,' and its companion tales, but his repute was ephemeral and he is now almost forgotten. With the mention of Frank R. Stockton, who wrote 'The Lady or the Tiger,' Edward Eggleston, George W. Cable, Elizabeth Stuart Phelps, Joel Chandler Harris, Francis Marion Crawford, Albion W. Tourgee, Lew Wallace (whose 'Ben Hur' became immediately popular upon its publication in 1881), Hamlin Garland, Harold Frederic, and Sarah Orne Jewett, the story of American fiction is brought down to a time when the beginnings of present-day reputations may be remembered by the youngest reader. Of Mark Twain and his work much could be said, for his later years were productive of famous novels: 'The Prince and the Pauper,' 'Jeanne D'Arc,' 'Pud'nhead Wilson,' 'Tom Sawyer,' and his other classics of American humor rank him among the great literary figures of the present era.

The leading note of contemporary American fiction is sounded from the West. With the exception of Howells, Wallace, Mark Twain, and one or two others, the first 80 years of our fiction is concerned wholly with writers native to the eastern and the southern portions of the United States. But toward the close of the 19th century, the western country began to develop writers of fiction. About the same time Mary E. Wilkins arose in the East, and James Lane Allen in the South, and each have gained no little reputation for the skilful manner in which they have set down the mingled characteristics of their own localities. Miss Wilkins has brought the short story into high estate through her picturesque handling of commonplace incidents and through her delineations of New England character, while Mr. Allen has been especially adept in his analysis of the human soul. The numerous novels written by Julian Hawthorne show the influence of heredity, and it is altogether likely that the son of Nathaniel Hawthorne might have made a higher position for himself in his chosen profession had he not been obliged to remain in the shadow of his father's great reputation. Frances Hodgson Burnett, although of English birth may be ranked through her long residence in this country as an American author. 'That Lass o' Lowrie's,' 'A Lady of Quality,' and the juvenile 'Little Lord Fauntleroy,' are evidence that she is not lacking at least in exceptional versatility. In 'The Prophet of the Great Smoky Mountains,' 'In the Clouds,' and other volumes of lengthy novels and short stories, Mary N. Murfree (Charles Egbert Craddock) has made herself the historian of the Tennessee mountain region. In 1888 Margaret Deland's 'John Ward, Preacher,' attracted wide attention to a writer, the excellence of whose work has ever since been kept at high standard. Robert Grant, with his 'Confessions of a Frivolous Girl,' and 'Unleavened Bread,' may be called the novelist of the social East, and Henry Harland, although his long residence in England has caused him to lose something of his American identity, is well known by such fantastic stories as 'The Cardinal's Snuff Box,' and 'The Lady Paramount.' Paul Leicester Ford, historian and bibliographer, wrote 'The Honorable Peter Stirling,' an artistic novel of political life notable from every point of view, and 'Janice Meredith,' a popular flamboyant novel.

The modern extravagant vogue of the historical novel has been stimulated and fostered especially by Mary Johnston and Winston Churchill. In the late nineties Booth Tarkington achieved a veritable *tour de force* with a remarkable little story called 'Monsieur Beaucaire.' The story of American fiction may fittingly be brought to a close with the name of Edith Wharton, whose genius as expressed in

‹The Touchstone,› ‹The Greater Inclination,› and ‹The Valley of Decision,› gives her unquestioned place among modern novelists.

EDWIN FRANCIS EDGETT,
Literary Editor Boston Transcript.

Bibliography. Abernethy, ‹American Fiction› (1902); Bates, ‹American Literature› 1896); Beers, ‹A Century of American Literature› (1878); Howells, ‹Literary Friends and Acquaintances› (1901); Matthews, ‹Aspects of Fiction› (1896); Richardson, ‹American Literature› (1889); Sears, ‹American Literature in the Colonial and National Periods› (1902); Tyler, ‹History of American Literature› (1897); Wendell, ‹A Literary History of America› (1901).

Fiddle-beetle. See FUNGUS-EATERS.

Fiddler-crab, the American name for the small and active crabs of the genus *Gelasimus,* called «calling crabs» by the English, who say they are waving the enormously developed front claw on the right side in beckoning, while the Americans imagine them to be fiddling. This great claw is brightly colored, and is used by the males not only as a weapon, but to be displayed as an attraction before the females. These crabs throng in thousands in salt-marshes near high-water mark, where they dig burrows.

Fides, fī'dēz, the Roman goddess of faith and honesty. Numa was the first who paid her divine honors.

Fiduciary, a law term signifying a relation of trust and confidence, generally by one acting as trustee, executor or administrator, or a director of a corporation.

Field, MRS. **Caroline Leslie,** American author: b. Milton, Mass., 10 Nov. 1853. She is a daughter of Mrs. A. D. T. Whitney (q.v.), and has published: ‹High Lights,› a novel (1885); ‹The Unseen King, and Other Verses› (1887); ‹Nannie's Happy Childhood› (1889); etc.

Field, Cyrus West, American merchant: b. Stockbridge, Mass., 30 Nov. 1819; d. New York 12 July 1892. He was the son of Rev. D. D. Field (q.v.). He early attained an important position in the mercantile world, and began to interest himself in ocean telegraphy. Having obtained a charter giving him the exclusive right for 50 years of landing ocean telegraphs on the coast of Newfoundland, he organized an Atlantic telegraph company for the purpose of laying telegraph cables across the ocean. Attempts to lay cables were made in 1857 and 1858, but without permanent success, though ships had been provided by the English and the American governments. The scheme was interrupted by the outbreak of the American Civil War, but a renewed attempt to lay a cable was made in 1865, the Great Eastern now being engaged in the work. About 1,200 miles had been laid by that vessel when the cable parted; but at last, in 1866, a cable was successfully laid by the Great Eastern, and the broken one recovered and completed. Mr. Field subsequently took an active part in establishing telegraphic communication with the West Indies, South America, etc., and was connected with various important enterprises.

Field, David Dudley, American Congregational clergyman: b. East Guilford (now Madison), Conn., 20 May 1781; d. Stockbridge, Mass., 15 April 1867. He was graduated at Yale in 1802; in 1804–18 held a pastorate at Haddam, Conn.; and in 1819–37 at Stockbridge, Mass. In 1837–51 he was again at Haddam. In addition to sermons he published: ‹History of Middlesex County, Conn.›; ‹History of Berkshire County, Mass.›; ‹Life of David Brainerd.›

Field, David Dudley, American jurist: b. Haddam, Conn., 13 Feb. 1805; d. New York 13 April 1894. He was a son of the preceding; was admitted to the New York bar in 1828; and practised till 1885, distinguishing himself especially by his labors in the direction of a reform of the judiciary system. In 1857 he was appointed by the State to prepare a political, civil, and penal code, of which the last was adopted by New York, and all have been accepted by some other States. In 1866, by a proposal brought before the British Social Science Congress, he procured the appointment of a committee of jurists from the principal nations to prepare the outlines of an international code, which were presented in a report to the same congress in 1873. This movement resulted in the formation of an association for the reform of the law of nations, and for the substitution of arbitration for war, of which Mr. Field was the first president.

Field, Edward, American antiquarian: b. Providence, R. I., 4 Oct. 1858. He was for years a school commissioner of Providence and served as city auditor pro tem. He was made clerk of probate 1889, and record commissioner of Providence 1891, is a member of several historical societies, and is historian of the Rhode Island Society of the Sons of the American Revolution. He has published: ‹Tax Lists of the Town of Providence during the administration of Sir Edmund Andros and his Council 1686–1689› (1895); ‹Revolutionary Defenses in Rhode Island› (1896); ‹The Colonial Tavern› (1897); ‹Esek Hopkins, Commander-in-Chief of the Continental Navy During the American Revolution 1775–1778› (1898); etc.

Field, Eugene, American journalist: b. St. Louis, Mo., 2 Sept. 1850; d. Chicago, Ill., 4 Nov. 1895. By his poems and tales in the press he won a high reputation in the West, which before his death had become national. His poems for children are admirable in their simplicity and in their sympathetic insight into the child's world of thought and feeling. His more important works comprise: ‹Culture's Garland› (1887); ‹Love Songs of Childhood›; ‹A Little Book of Western Verse›; ‹A Little Book of Profitable Tales› (1889); ‹A Second Book of Verse›; ‹The Holy Cross, and Other Tales›; ‹The Love Affairs of a Bibliomaniac.› In collaboration with his brother, R. M. Field (q.v.), he published translations from Horace, ‹Echoes from the Sabine Farm.›

Field, Henry Martyn, American clergyman and scholar: b. Stockbridge, Mass., 3 April 1822; d. there 26 Jan. 1907. He was graduated at Williams College, and was ordained to the ministry in 1842. In 1854 he became editor and proprietor of the New York ‹Evangelist.› He was a lifelong traveler. Among his works are: ‹Summer Pictures from Copenhagen to Venice› (1859); ‹History of the Atlantic Telegraph' (1866); 'From the Lakes of Killarney to the Golden Horn' (1876); 'From Egypt to Japan' (1878); 'On the Desert' (1883); 'Among the Holy Hills' (1883); 'The Greek Islands and Turkey After the War' (1885); 'Our Western Archipelago'; 'The Barbary Coast'; 'Old Spain and New Spain'; 'Gibraltar'; 'Bright Skies and Dark Shadows.'

Field, Marshall, American merchant: b. Conway, Mass., 18 Aug. 1835: d. New York City 16 Jan. 1906. He received a common school and academic education in the intervals of labor on his father's farm. At 17 he entered a dry goods store in Pittsfield, Mass., as clerk, soon mastered the details of the business, and in 1856 removed to Chicago, where he entered the employ of Cooley, Wadsworth & Co., a pioneer mercantile house. In 1860 he was admitted to a junior partnership in the firm, which then became Cooley, Farwell & Co., and later Farwell, Field & Co. On the dissolution of this partnership the firm of Field, Palmer & Leiter was formed in 1865, and on the retirement of Palmer, two years later, the firm name became Field, Leiter & Co. In 1881 the Leiter interest was purchased by Mr. Field and the business was afterwards continued under the firm name of Marshall Field & Co. Prior to the Chicago fire of 1871 the sales amounted to $12,000,000 annually, but have since steadily increased to more than $60,000,000, the firm being now the largest dry goods house in the world. The single large building, which it occupied before the fire, has been replaced by one much larger devoted to the retail trade, the wholesale business being carried on in an immense building covering an entire block. In addition to these two vast establishments the house has offices in New York, England, France, Germany, Switzerland, and Japan. Avoiding ostentation Mr. Field was a liberal and discriminating giver. In addition to the Field Columbian Museum (q.v.) given by him to Chicago, he bestowed gifts upon the University of Chicago, and to his native town of Conway he gave and endowed a public library, at a cost of $200,000, in memory of his parents.

Field, Mary Katherine Kemble, American author and lecturer: b. Saint Louis, Mo., 1838; d. Honolulu, Hawaii, 19 May 1896. Among her books are: 'Planchette's Diary' (1868); 'Ten Days in Spain' (1875); 'History of Bell's Telephone'; 'Life of Fechter'; 'Haphazard'; etc. Consult Whiting, 'Kate Field.'

Field, Stephen Johnson, American jurist: b. Haddam, Conn., 4 Nov. 1816; d. Washington, D. C., 9 April 1899. He was the second son of the Rev. David Dudley Field (q.v.), and a brother of David Dudley Field (q.v.), jurist and law reformer and of Cyrus W. Field (q.v.), the inventor of the Atlantic cable. When he was 13 years of age young Field journeyed to the East with his brother-in-law, who was a missionary, and spent three years in Smyrna and Athens, studying Greek and other languages. After returning to America he graduated at Williams College, and for a time thereafter studied law in New York city. In 1848, soon after he was admitted to the bar, he went to Europe where he remained for one year. In 1849 he joined the rush of easterners to the new gold diggings in California, and settled at the mining camp known as Yubaville, since called Marysville. Here he was elected first alcalde under the old Mexican law of that region, holding office until the organization of the judiciary under the Constitution of the State. In 1850 he was elected to the State Legislature and was placed on the judiciary committee. He drew up several bills providing for articles in the State Code and some of his laws for miners and mining were afterward adopted by other States. In 1857, he was elected judge of the supreme court of California and two years later succeeded Judge Davis S. Terry (q.v.) as chief justice. The decisions of Justice Field in the next few years had much to do with the law of real property and large areas of disputed property was assigned to legal ownership through his decision. In 1863, President Lincoln appointed him an associate justice of the Supreme Court of the United States, which important position he held until 1897. Among his important decisions and opinions were those of the income tax cases, test oath cases and legal-tender cases. He became eminent as one of the most celebrated authorities on constitutional law. In 1876 he was a member of the famous electoral commission which decided the Presidency in favor of Rutherford B. Hayes of Ohio, as against Samuel J. Tilden of New York. His service on the bench of the Supreme Court was the longest in the history of that learned body.

Field of the Cloth of Gold, a spot in the valley of Andren, between the English castle of Guisnes and the French castle of Ardres, celebrated for the meeting between Henry VIII. of England, and Francis I. of France, attended by the flower of nobility of both nations. The meeting took place 7 June 1520, and had been planned by Cardinal Wolsey, to enable the two kings to come to an understanding as to an alliance against Charles V. of Spain.

Field, Columbian Museum, a scientific institution of Chicago, Ill., established through gifts by Marshall Field (q.v.) and other citizens, and opened in 1894.

Field Cricket, a large European cricket (*Gryllus campestris*), found in hot, sandy localities, where it burrows. See CRICKET.

Field Dogs, a general name applied by sportsmen to such dogs as assist them in field sports, such as pointers, setters, spaniels, and the like. See DOG.

Field, Magnetic, or **Field of Magnetic Force,** a term introduced by Faraday to designate any space possessing magnetic properties. A space may possess magnetic properties either on account of magnets in its vicinity, or on account of currents of electricity passing through or round it. See ELECTRICITY; ELECTRO-MAGNETISM; FARADAY; MAGNETISM.

Field-marshal, the highest military dignity in Great Britain, Germany, and other European countries. George II. introduced the title into England when, in 1736, he created the Duke of Argyll and the Earl of Orkney field-marshals, but it had been long in use in the German armies, and is of German origin. In Great Britain the dignity is conferred by selection and is held by but few officers, and chiefly for distinguished services or on the ground of royal descent.

Field Mice, or **Voles,** any wild mouse, dwelling in fields and open places, may be called a field mouse; but the name applies more strictly to the robust, short-tailed mice of the arvicoline group of the family *Muridæ*, representatives of which occur throughout the north temperate zone, and are known in Great Britain as «voles.» The same group includes the lemmings, muskrats and other vole-like mice dwelling in the woods. The common field-mice of the United States and Canada are of the genus *Microtus*, and the common eastern «meadow-mouse» (*M. pennsylvanicus*) is distributed over the whole continent, showing many local variations in color and form. It is 5½ inches long, with the tail 1½ inches; grayish brown with chestnut tinges, blackish on the spine, and hoary below. A near relative of the upper Mississippi valley is the prairie meadow-mouse (*M. austerus*), which is larger and more uniformly gray; and another is the southern pine-mouse (*M. pinetorum*), whose coat is rusty brown, short, dense and silky. Other species are distinguished on the Pacific coast. These mice feed mainly upon seeds and bark, and often do vast damage in grain fields, where they not only eat or shake down a large percentage of the crop, but occasionally overrun the country in vast hordes suitably described as «plagues.» This has happened repeatedly in Europe, where the offending species was the very common field-vole (*M. agrestis*), whose inroads have sometimes nearly produced famine in southern Russia. In winter these pests of the farmer are likely to nibble the bark from young fruit-trees until they have been fatally girdled. These mice dwell in shallow burrows, or make nests of grass in various hiding places, being especially fond of working their way into grain stacks and storage-cellars. They pass the winter in these retreats, sustained by a store of seeds, etc., but hibernating only during the severest weather. The best way to combat them is not to kill off their natural enemies, the hawks, owls, harmless snakes and small carnivores. To the unwise destruction of these is due most of the «plagues» of mice. Consult Audubon and Bachman, ‹North American Quadrupeds› (1846); Godman, ‹Natural History› (1834); Kennicott's papers in the Annual Report of the U. S. Department of Agriculture for 1857; Ingersoll, ‹Wild Life of Orchard and Field› (1901); and Stone and Crane, ‹American Animals.›

Field Plover, a sportsmen's name for several different shore-birds, most commonly meaning the upland or Bartramian sandpiper (*Bartramia longicauda*), which resembles a killdeer (q.v.) in habits, but is not a true plover. It is 12 to 13 inches long, light-brownish, marked with ochraceous and blackish; throat nearly white, and tail-feathers mostly marked with white. It is related to the European ruff.

Field Spaniel. See Dog.

Field Sparrow, a small familiar sparrow (*Spizella pusilla*) of North American fields and meadows, closely related to the garden chipping-sparrow (q.v.), from which it differs in being slightly larger and much paler in colors. Its song, however, more resembles that of the song-sparrow. It nests on the ground, and lays white eggs speckled with reddish and purple.

Fieldfare, a European thrush (*Turdus pilaris*) prevailingly grayish-brown with darker markings and lighter under parts. It breeds in Scandinavia and northern Russia, making nests in companies in trees, and visits Great Britain and southern Europe in winter, where it is largely shot for market.

Fielding, Anthony Vandyke Copley, English painter in water colors: b. about 1787; d. Worthing, Sussex, 3 March 1855. He early attracted attention by his water-color landscapes; gained also considerable reputation as a teacher, and for many years before his death was president of the Society of Painters in Water Colors. His pictures are chiefly taken from English scenery, the various features of which, both in rich woodland and open plain, he has represented with great delicacy and truth.

Fielding, Henry, English novelist: b. Sharpham Park, near Glastonbury, in the county of Somerset, 22 April 1707; d. Lisbon, Portugal, 8 Oct. 1754. His parents were Lieutenant Edmund Fielding and his wife Sarah, daughter of Sir Henry Gould. It is believed that in the characters of Lieutenant Booth and Amelia, Fielding long afterward revived the figures of his young father and mother. By an old legend, put into magnificent form by Gibbon, the novelist was supposed to have descended from the Hapsburgs, but their connection with the ancient family of the Earls of Denbigh, to which the novelist certainly belonged, is now exploded. The Fieldings of Sharpham, though of moderate means, were well connected; the novelist's cousin was the famous Lady Mary Wortley Montagu. In 1710 his parents removed, on the death of Sir Henry Gould, to East Stour in Dorsetshire, where Sarah Fielding (1710–1768), Henry's sister and the gifted author of ‹David Simple,› was born. To his childish adventures by the «pleasant banks of sweetly-winding Stour» Henry gives due record in ‹Tom Jones.› He was 11 years of age when the family moved again, after the death of Mrs. Fielding in 1718, and Henry was transferred to Eton. There is no record of his residence in the registers of the school, so that he was probably an oppidan. Murphy tells us that Fielding, when he left Eton, about 1726, «was said to be uncommonly versed in the Greek authors, and an early master of the Latin classics;» Fielding himself tells us that he knew Italian and French, could write Latin and could read Greek. The early idea that he was a poorly-educated man was based on prejudice and ill-will. Pitt and Fox were among his comrades at Eton. Before he left school, he fell in love with Sarah Andrew, a young lady of Lyme Regis, and even planned her abduction, but the affair was discovered by her guardians, who prevented the romantic act, although, as the archives of the town still record, going in fear of their lives «owing to the behavior of Henry Fielding and his attendant, or man.» This Miss Andrew was said to be the original of Sophia Western.

From Eton Fielding proceeded to study law at Leyden for two years, which he did «with a remarkable application.» He settled in London early in 1728, doubtful whether to adopt, as

Austin Dobson says, the profession of hackney-writer or that of hackney-coachman; his father could no longer support him, and it was necessary for him to subsist upon his wits. He determined to turn playwright, but his earliest drama, the comedy of 'Love in Several Masques,' had no great success. It is difficult to trace the history of Fielding further during the next two years, but in 1730 he brought out another comedy, 'The Temple Beau,' and an extravaganza, 'The Author's Farce.' These were not unsuccessful, and they opened a long series of dramatic performances, by means of which it would seem that Fielding obtained a precarious livelihood for the next seven years. The very entertaining burlesque of 'Tom Thumb' (1730), especially in its extended form as 'The Tragedy of Tragedies' (1731), deserves a high position among these plays, most of which were of somewhat ephemeral importance. In 1732 Fielding produced 'The Modern Husband,' 'The Covent Garden Tragedy,' 'The Debauchees,' and 'The Mock-Doctor;' the last-mentioned comedy was highly successful, and so was 'The Miser,' of 1733, but Fielding's share in the profits of these pieces cannot have been large. He lived, no doubt, on what he could borrow, earn, or beg; sometimes in a London garret, sometimes in the country-house of a wealthy acquaintance. A satirist of the period describes him at this time as a "rough play-house bard," and "clad in coarse frieze," while his best biographer infers that his daily life must have been more than usually characterized "by the vicissitudes of the eighteenth-century prodigal." 'The Intriguing Chambermaid' was Fielding's principal contribution to 1734, but the prolific dramatist was now beginning to find that the town had become sated with his light any spicy confections. The date on which Fielding married Miss Charlotte Cradock, a respectable lady of independent means living at Salisbury, to whom he had for some years been attached, was long unknown, but it has recently (1906) been discovered that the marriage took place, by license, in the church of Saint Mary's, Charlcombe, close to Bath, on 28 November, 1734. It is at this time, and on Miss Cradock's money, that he has been believed to have begun "immediately to vie in splendor with the neighboring country squires," and to have maintained a large retinue of servants, "all clad in costly yellow liveries." This story has been criticised, and, in some of the particulars with which Murphy adorns it, it must be inexact in detail, yet it probably gives not an unfair impression of the lavish way in which, for about a year, Fielding lived in Dorsetshire in a magnificence far beyond his means. His cousin, Lady Mary, said that Henry Fielding "would have wanted money if his hereditary lands had been as extensive as his imagination," and in a few months he was back in London, again obliged to work for a precarious living. He returned to the drama, and in 1736 took the little French Theatre in the Haymarket, where he produced the successful burlesque of 'Pasquin,' by which he made more money than by any of his previous efforts. His career as a dramatic author, however, was checked by a Bill of 1737, in which Parliament restrained the license of the stage, and reduced the number of playhouses. The rest of the few and slight puppet-shows and farces which Fielding wrote need not be named here. His plays (they are 25 in number) although skilful and sprightly, have not the value of his novels, nor anything like their originality, and they are read to-day, if they are read at all, because they are Fielding's, and not because of their intrinsic merit.

When his company of actors was dispersed, Fielding turned to the law as a profession, and in November 1737, became a student of the Middle Temple. According to Murphy, he studied with great assiduity, but little is known of his life at this time. He eked out his legal work with the writing of "a large number of fugitive political tracts," which were probably anonymous, and have disappeared. Late in 1739 he started a newspaper, the 'Champion,' on the model of the 'Tatler,' and in this journal he wrote much, until June 1740, when he was called to the Bar. He traveled the Western Circuit, and "assiduously attended the Wiltshire sessions." He seems to have taken his duties as a barrister very seriously, but they did not prevent him from writing, and publishing in February 1742, the novel of 'Joseph Andrews.' This began as a parody of the popular 'Pamela' of Richardson, but soon passed on into an independent and highly entertaining study of contemporary manners. The fresh and breezy genius of Fielding mocked at the sentimentalities and the wire-drawn psychology of his predecessor, but he soon got beyond the point where it was enough for him to ridicule Richardson. He created two magnificent comic figures of his own, and he enriched English literature forever with Parson Adams and Mrs. Slipslop. It was thus that, at the age of 35, Fielding discovered, as it were by accident, the nature of the genius which he possessed. He did not, however, at once perceive the value of the discovery, but returned to his plays and his pamphlets. It was now that he published two early farces, 'Miss Lucy in Town' (1742), and 'The Wedding Day' (1743), as well as a much more important work, his 'Miscellanies,' in three volumes. This was a collection of Fielding's shorter writings up to that date, and included his poems, occasional and satirical, his essays, his 'Journey from this World to the Next,' some of his farces, and the remarkable ironic novel called 'Jonathan Wild.' The 'Journey' is a Lucianic allegory, full of wit and observation, but unfortunately left unfinished by the languor of the author, who evidently became weary of his design. 'Jonathan Wild' is a work of far greater importance. It takes for its hero a notorious rogue who was hanged at Tyburn in 1725, and there is internal evidence that although not printed until 1743, it was written some years before. It is probable that it preceded 'Pamela,' and ought to take its place as the earliest of the novels of the new school of romance. It is a powerful and painful book, "a picture of complete vice, unrelieved by anything of human feeling," and more unflinching than anything else which Fielding has left. It is a curious thing that from this date until 1749 we have a period of six years, during which Fielding was at the height of his powers, and was not without a certain measure of celebrity, yet which have left scarcely any mark at all upon his history. How was this great man engaged from his 37th to his 44th year? Strange as it sounds, we cannot tell. Austin Dobson has brought forward arguments to show that it was a time of poverty, darkened by successive bereavements, particularly that of the loss of his wife, to whom he was most tenderly attached. A remarkable preface, prefixed to the second edition of his sister's 'David Simple,' appeared in 1744; in this he denies his authorship of the work itself. He describes himself as applied to the legal profession "with so arduous and intelligent a diligence" that he has no time for the practice of literature. He wrote a little, however, for 'The True Patriot' and other journals. In November 1747 Fielding married for the second time, and took a house at Twickenham; Mary Daniel, the second Mrs. Fielding, is said to have been her predecessor's "cook-wench." Fielding had by this time secured an invaluable friend in George, afterwards the first Lord Lyttelton (1709–1773), who procured for him, in December 1748, the office of a Justice of the Peace for Westminster. Up to this date he had been a wanderer on the face of England, now at Salisbury, now at Twiston, at Hagley, at Twickenham, but in January 1749 he settled for good in London. John, Duke of Bedford lent or rented to him a house in Bow Street, under terms which were described as a "princely instance of generosity." But Lyttelton was the closest of all Fielding's influential friends, and there is a remarkable passage in which the novelist states that he partly owed to Lyttelton his existence during a great part of the time spent in the composition of 'Tom Jones,' a book which, without Lyttelton's help, "had never been completed." It used to be stated that 'Tom Jones' was written at Bow Street, but this is impossible; it was evidently the work of the desultory months of poverty which preceded Fielding's appointment as a magistrate. The famous novel was published, as 'The History of Tom Jones, a Foundling,' on 28 Feb. 1749, in six volumes, at the price of 16 shillings a set. It had an instant success, so great that, three month later, Fielding had already received £700 from Millar, the publisher. That this did not much alter the random habits and easy negligence of the author seems to be proved by a picturesque although spiteful description given by Horace Walpole, in May 1749, of Fielding dining at the house in Bow Street "on some cold mutton and a bone of ham, both in one dish, and on the dirtiest cloth," in the company of some very questionable persons. It is well to look at the other side, and to remember, with Murphy, that Fielding "kept his table open to those who had been his friends when young, and had impaired their own fortunes." It is certain, moreover, that he was increasingly respected by those who could overlook the carelessness of his habits and his easy nonchalance of manners.

In May 1749 he was unanimously elected chairman of Quarter Sessions, and his magisterial charges were received with all the respect which their gravity and courage demanded. How seriously he took the duties of his office is seen in his 'True State of the Case of Bosavern Penlez' (1749), in which he vindicates the severity of the law against rioters. This was a time of great lawlessness among the London lower classes, and Fielding eminently distinguished himself by his vigilance against violent criminals and by his plans for reform. But his health was already failing; he had lived too hard and too fast, and on Hurd, who met him in 1751, the novelist produced the impression, at 44 of "a poor, emaciated, worn-out rake." There was, however, no intellectual decline, and, at the close of this same year, there appeared the very vigorous and pathetic romance, 'Amelia.' This novel has had its enthusiastic admirers, but, to the charge that it is less broad and fresh than its immediate predecessor, there is no reply. As Fielding's best biographer has said, "Behind 'Tom Jones' there was the author's ebullient youth and manhood; behind 'Amelia' but a section of his graver middle-age." There is a remarkable sense of decline in the juvenile vigor which was so irrepressible in 'Tom Jones'; the author of 'Amelia' writes philosophically, and like an elderly man. In the figure of the heroine, however, there was no evidence of declining powers; here is the most exquisite figure of a woman that Fielding ever painted. In 1752, Fielding, although so much occupied, found the energy to start the bi-weekly, 'Covent Garden Journal,' which led him into acrimonious controversy with Smollett and others; and to collect the narratives of peculiar cases of the detection of murder which had come under his notice as a magistrate, in 'Examples of the Interposition of Providence.' In 1753 he was deeply interested, like all his contemporaries, in the mysterious case of Elizabeth Canning, who professed to have been kidnapped, and he published a pamphlet on the subject. But he was by this time greatly reduced by successive attacks of the gout, and in August of that year was ordered to retire to Bath. His going, however, and the proper treatment of his disease, were delayed by his great wish to break up a congeries of gangs of street robbers, who were committing murders in London so frequently as to alarm the government itself. But when, in December, he had at length completed this public duty, his was "no longer a Bath case," and he was so much weakened by jaundice, dropsy and asthma, that he looked upon his condition as almost desperate. He struggled through the winter, and in June 1754 started, in search of relief, for Portugal. The tediousness and multiplied discomforts of the transit are described, with a great deal of heroism, in the 'Journal of a Voyage to Lisbon,' which was the latest and one of the best written of Fielding's works. He traveled with all his family, and they arrived in the Tagus in August. No further particulars have been preserved, but that Fielding died at Lisbon, on 8 Oct. 1754, and was buried in the beautiful cemetery of Os Cyprestres, opposite the Church of the Estrella.

With regard to the importance of Fielding's work in the development of English literature there is a complete unanimity of opinion among all competent critics. Indeed, there is scarcely a reputation which is less liable to be challenged than his. Without insisting on the title of "Father of the British Novel,"— which must belong, if it be given to anyone, to Defoe or to Richardson,— we cannot but admit that it was Fielding who first in Europe foresaw the full scope of the "comic epic poem in prose," and that his own efforts in that direction have, at their best, never been excelled. The symmetry of his books, particularly of that matchless work of art, 'Tom Jones,' has not been surpassed, and this is the more wonderful because, until his day, no one had perceived the fact that a work of prose fiction needs to be symmetrical.

He relieved the excessive strain of feeling, which, in the case of Richardson, had sometimes amounted to a positively distressing tension, by introducing breaks of witty observation, ironic illustration, or entertaining episode, but he did this with a care for the balance of parts which makes the study of his technique extremely interesting. Byron called Fielding "the prose Homer of human nature," and in so doing he indicated the extraordinary range of sympathy which marks his delineation. There is nothing unnatural or extravagant about the incidents which he introduces, but they are such as might be expected inevitably to happen to such very natural characters as the novelist depicts.

It has been said that Fielding lacked the imaginative faculty. It would be more correct to say that he distrusted the fantastic and preposterous parts of invention, since, if imagination is the power to bring up before one's own mental vision, and to reproduce for others with fidelity a consistent chain of phenomena, then Fielding was fully endowed with that gift. His pictures are remarkable for their brightness, their freshness, the sharpness and illumination of their outline. His invention occupied itself, not with the unusual, but with the obvious scenes of life, which in his day were, fortunately, still unhackneyed. He wrote slowly and finished late; he did not hasten to exhaust the stores which adventure and experience had given him; he had warmed both hands before the fire of life, and he gave back to the world in his books what he received from it in his own rough-and-tumble youth. From Fielding we must not look for pathos or romantic sentiment,— although even these are not wholly missing,— but we must look for humor, breadth of sympathy, a genial buoyancy, a wholesome recognition of the appetites, a philosophic consideration of the limitations of human frailty, and these we find in his wonderful novels to a degree which we may without fear of exaggeration confess to be elsewhere unparalleled.

Bibliography.— Fielding's earliest biographer was Arthur Murphy (1727–1805), who prefixed an essay on his life and genius to the first collected edition of his 'Works' (1762). Murphy's inexactitudes were pointed out by Lawrence in 1855, and by Keightley in 1858, but by far the most accurate and dispassionate life of Fielding is that published by Austin Dobson in 1883. Subsequent editors and biographers have been content to borrow the main part of their information from this admirable monograph, which has been corrected by the author in successive editions, and is now not likely to be superseded as the standard authority on the life and bibliography of Henry Fielding.

Edmund Gosse,

Author of 'History of 18th Century Literature'; 'History of Modern English Literature'; etc.

Fielding, Sarah, English novelist: b. East Stour, Dorsetshire, 8 Nov. 1714; d. Bath, Somerset, April 1768. She was the third sister of Henry Fielding (q. v.). She was the author of the novel 'David Simple' (1744); 'The Governess' (1849); 'The Cry, a Dramatic Fable' (1757); Xenophon's 'Memoirs of Socrates,' translated from the Greek; 'The Countess of Delwyn'; 'The History of Ophelia'; 'The Lives of Cleopatra and Octavia'; etc.

Fielding, William Stevens, Canadian statesman: b. Halifax, Nova Scotia, 24 Nov. 1848. He was educated in Halifax; for 20 years was connected with the Halifax 'Morning Chronicle,' becoming managing editor; but resigned that position to enter public life. From 1882–96 he represented the city and county of Halifax in the Provincial Legislature, soon after his election becoming a member of the Cabinet and from 1884–96 Prime Minister. In 1896 he resigned to enter the Cabinet of Sir Wilfred Laurier as Minister of Finance. He also represents the electoral district of Shelburne and Queen's in the Dominion Parliament. He represented Canada at the Colonial Conference, London, 1902, and is a governor of Dalhousie University. Among other important works, he has readjusted the Canadian tariff, submitted to Parliament, the British preferential tariff, and later the measure imposing a surtax on German products, and legislation regarding the so-called "dumping" system.

Fields, Annie, (Adams), American poet and essayist, wife of James T. Fields (q.v.): b. Boston, Mass., 6 June 1834. She has long been prominent in charity organizations and has published: 'Under the Olive,' poems (1881); 'Biography of James T. Fields' (1884); 'How to Help the Poor' (1885); 'The Singing Shepherd'; 'Authors and Their Friends'; 'A Shelf of Old Books' (1896); 'Life and Letters of Harriet Beecher Stowe' (1897); 'Whittier: Notes of His Life and Friendships'; 'Nathaniel Hawthorne' (1899); 'Orpheus a Masque' (1900).

Fields, James Thomas, American publisher and author: b. Portsmouth, N. H., 31 Dec. 1817; d. Boston 24 April 1881. He went to Boston in 1834, becoming junior partner of the firm of Ticknor, Reed & Fields in 1839, later known as Ticknor & Fields, and Fields & Osgood. He edited the 'Atlantic Monthly' 1862–70; and was an acceptable lecturer on literary subjects and authors. He published: 'Poems' (1849); 'A Few Verses for a Few Friends' (1858); 'Yesterdays with Authors' (1872); 'Hawthorne' (1875); 'Old Acquaintance: Barry Cornwall and Some of His Friends' (1875); 'In and Out of Doors with Dickens' (1876); 'Underbrush' (1881), Essays; 'Ballads and Other Verses' (1881): and (with E. P. Whipple) edited 'The Family Library of British Poetry' (1878).

Fieri Facias, fī'ē-rī fā'shĭ-as, in law, is a judicial writ of execution issued on a judgment, by which the sheriff is ordered to levy the amount of the judgment on the goods and chattels of one party, for the benefit of another. Abbreviated to *fi. fa.* See Execution.

Fieschi, or **Fiesco, Giovanni Luigi de,** jō-vän'nē loo ē'jē dē fē-es'kē or fē-es'kō, Count of Lavagna, Italian conspirator: b. Genoa 1523; d. there 2 Jan. 1547. He became master of a large patrimony at the age of 18, and being surrounded with dependents and flatterers, and really possessing considerable talents and eloquence, was readily induced to aim at that power and distinction in the state which was then possessed by the family of Doria, headed by the famous Andrea Doria, doge of Genoa. He attempted to kill the doge and overthrow the government, but was unsuccessful in both endeavors, and in his efforts to seize the public galleys was accidentally drowned.

Fieschi, Giuseppe Maria, fe-es'ke, Corsican conspirator: b. Corsica 3 Dec. 1790; d. Paris 16 Feb. 1836. Having conceived a hatred for the French king, Louis Philippe, he constructed an infernal machine of about 100 gun-barrels fixed in a frame, which he discharged simultaneously, by means of a train of gunpowder from a house in the Boulevard-du-Temple, during a review of the National Guard 28 July 1835. The king escaped unhurt, but Marshal Mortier and 17 people were killed, and many more wounded. Fieschi and his accomplices, Pepin and Morey, were guillotined.

Fiesole, Fra Giovanni Da. See FRA ANGELICO.

Fiesole, fē-ā'sō-lĕ (ancient FÆSULÆ), Italy, city about four miles northeast of Florence. Under the name of Fæsulæ it was one of the 12 Etruscan cities, and a place of importance. It submitted, with the rest of Etruria, to the Roman power (90 B.C.), and was colonized by Sylla. In the commencement of the 11th century it was destroyed by the Florentines, and a number of its inhabitants transported to Florence. It contains many interesting Etruscan ruins; but it is noted as being the place where Fra Angelico (q.v.) lived for a number of years. Pop. 5,000.

Fiévée, Joseph, zhō-zeph fyā-vā, French journalist: b. Paris 10 April 1767; d. there 7 May 1839. His experiences during the French Revolution were not happy, largely in consequence of his work: 'On the Necessity of a Religion' (1795); but the Napoleonic rule proved more favorable to him. He subsequently wrote two novels, 'Suzette's Dowry'; and 'Frederick'; besides historical works on aspects of the republic, consulate, and empire.

Fife, a wind-instrument, known from very early times and used chiefly in military music. It resembles a small flute in its form and method of performance, seldom having any keys, and never more than one. It has six finger holes. Fifes are of several kinds. Those tuned to the key of C are shortest and highest, and are much oftener used; they have a compass of two octaves. The instrument is characterized by a clear and piercing tone.

Fifer, Joseph W., American soldier and public man: b. Staunton, Va., 20 Oct. 1840. When a boy he went with his parents to Illinois, and enlisted in the Union army in 1861; he was wounded at the battle of Jackson in 1863, but rejoined his regiment and served until 1864. After the war he was graduated from the Illinois Wesleyan University, studied law, and was admitted to the bar. He was corporation counsel for the city of Bloomington in 1871, and State's attorney for McLean County 1877–80. In 1880 he was elected to the State senate and served four years; in 1888 he was elected governor of Illinois on the Republican ticket, but in 1892 was defeated for re-election by Altgeld. In 1904 he was appointed a member of the Interstate Commerce Commission.

Fifteen Decisive Battles of the World, a noted work by Sir Edward Shepherd Creasy, published 1852. It describes and discusses (in the words of Hallam) "those few battles of which a contrary event would have essentially varied the drama of the world in all its subsequent scenes." The volume treats, in order: The Battle of Marathon, 413 B.C.; Defeat of the Athenians at Syracuse, 413 B.C.; The Battle of Arbela, 331 B.C.; The Battle of the Metaurus, 207 B.C.; Victory of Arminius over the Roman Legions under Varus, 9 A.D.; The Battle of Châlons, 451; The Battle of Tours, 732; The Battle of Hastings, 1066; Joan of Arc's Victory Over the English at Orleans, 1429; The Defeat of the Spanish Armada, 1588; The Battle of Blenheim, 1704; The Battle of Pultowa, 1709; Victory of the Americans over Burgoyne at Saratoga, 1777; The Battle of Valmy, 1792; The Battle of Waterloo, 1815.

Fifth, one of the five equal parts into which any unit may be divided. In music, it is a distance comprising four diatonic intervals, that is, three and a half tones. It is the second of the consonances in the order of their generation. As consecutive fifths do not produce a good effect, they are not allowable in harmony. There are three kinds of fifths: namely, the perfect fifth (C — G), consisting of three whole tones and a semitone; the flat, diminished, or imperfect fifth (B — F), consisting of two whole tones and two semitones; and the extreme sharp, or superfluous fifth (C — G sharp), composed of four whole tones.

Fifth Monarchy Men, a set of politico-religious enthusiasts who sprang up during the Protectorate of Cromwell. They believed that the four great kingdoms mentioned by Daniel, the Assyrian, the Persian, the Grecian, and the Roman, were to be followed by the descent of Christ, to establish a fifth monarchy, which was to be of world-wide extent. They thought that this advent was close at hand, and that physical force should be employed to pave the way for Christ's reign. When the sect, who were of the extreme republican type, fancied Cromwell was aiming at the royal title as well as power, they raised a conspiracy against him (1657), which was quickly discovered. Their leaders were thrown into prison, and were only liberated on the death of the Protector. The sect became extinct shortly after the Restoration.

Fifth Nerve, the chief sensory nerve of the face, also called trigeminus, or trifacial. It is one of the fifth cranial pair of nerves. The fifth nerve is one of the most important sensory nerves of the body, its name trafacial meaning that it has three large divisions which are distributed to the face, and its name trigeminus being given because it has three roots inside the skull. It is really a mixed nerve containing both motor and sensory fibres. The motor root rises from a group of cells lying deep in the floor of the fourth ventricle. The sensory portion arises in a series of ganglia, the Gasserian ganglion being the most important one. The ophthalmic and Meckel's ganglia are also smaller ganglionic centres. The chief branches go to supply the entire area of the skin of the face and head, and neuralgias and neuritides of the face and head are due to affections of this nerve. The chief division is the first or ophthalmic division, which supplies the region over the superior surface of the nose, forehead and eye, running as far back as the top of the head. The second branch is the superior maxillary, which supplies the teeth and the region of the skin beneath the orbit, the upper lip, and the region of the temple. The superior maxillary nerve constains a few motor fibres. The third branch, the inferior maxillary, or mandibular, is the largest branch of the fifth nerve, and contains most of the motor fibres. It supplies the surface of the skin of the lower jaw, front of the ear, and temporal region, lying close behind the area supplied by the maxillary. The muscles of the jaw, the masseters, temporals and buccinators are supplied by the motor fibres of this branch. See CRANIAL NERVES; FACIAL NEURALGIA; NEURALGIA.

Fifty-four Forty or Fight, the slogan of the Northern Democrats in 1844; meaning the insistance upon the line of lat. 54° 40′ N. as the southern limit of English possession, even at the price of a war. The Ashburton Treaty of 1842 had created great dissatisfaction as a surrender of American rights (and in England as a surrender of British rights), and the hot-heads wished to abrogate it. But the Southern leaders did not wish to make war for the increase of free territory, and instead diverted the war sentiment against Mexico, forcing on the Mexican war of 1847.

Fig, the fruit of the *Ficus carica,* a native of Asia, Africa, and the south of Europe, which has been cultivated from remote antiquity in the countries surrounding the Mediterranean, where figs form a principal article of food in many places. It belongs to the natural order *Artocarpaceæ,* sub-order *Moreæ.* The male and female flowers are mixed indiscriminately on the inside of a fleshy receptacle, which is concave in form, with its edges drawn together into a narrow opening. What are called the seeds in the ripe fig are the pericarps, each containing a single seed. The fig-tree is distinguished from almost all others by the extraordinary property of producing two crops of fruit in the same year on distinct shoots, in climates congenial to its growth. The shoots formed by the first or spring sap put forth figs at every eye as soon as the sap begins to flow again in July and August. These figs which form the second crop of the year ripen in their native climate during the course of the autumn, but rarely if ever come to perfection in England. The shoots formed by the second flow of sap, commonly called midsummer shoots, put forth figs in like manner at every eye, but not until the first flow of sap in the following spring. These last-mentioned figs, which form the first crop of each year, ripen in warmer climates during the month of June and July, but not in this country before September or October. The fig-tree, in its wild state, is a low, distorted shrub, bearing fruit destitute of any agreeable flavor. Dried figs are easier of digestion and more nourishing than the fresh fruit, and form a considerable article of commerce. The best come from Turkey, Italy, Spain, and Provence; those of the Archipelago are inferior in quality. Dried figs, with barley bread, are now the ordinary food of the lower classes in Greece and the Archipelago. While the edible fig of commerce can be raised over the whole United States south of Philadelphia, fig culture was never considered a practical venture until a few years ago. American figs even in such a climate as California were shrunken and sour for the most part, and the dried Smyrna fig was still imported to the United States to the value of about $700,000 a year. As the price of other kinds of native fruit decreased, because of overproduction, many Californian orchardists and horticulturists turned their attention to the fig, which is among the costliest of dried fruits, being valued at from $200 to $400 a ton in the New York market. Cuttings of the Smyrna fig were imported to this country as early as 1880, but the fruit proved shrunken and tasteless. It was found necessary to start from seedlings and for this process caprification (q.v.) was necessary. In 1891 a consignment of *Blastophaga grossorum* was brought to this country. It was received by James Shinn of Niles, Cal., who had planted a caprifig tree in his orchard as a hospice for the insects. He failed of success through the lateness of the season at which he made the experiment, which, however, was repeated by George C. Rœding of Fresno, Cal., who met with complete success, and now Smyrna figs are produced in California as large and highly sugared as those which can be imported.

Fig-eater, a beetle of the genus *Allorhina* harmful to figs. See JUNE BEETLE.

Fig Fertilization by Insects. It was known to the ancients, according to Pliny and others, that the cultivation of certain varieties of figs was dependent for fertilization (technically termed caprification), upon the friendly aid of a minute hymenopterous insect termed the fig-wasp (*Blastophaga grossorum*). Beginning about 1890 numerous attempts were made to introduce the Smyrna and caprifigs in fig-growing sections of America. Recognizing our inability to fertilize the female varieties which were introduced, experiments were made with mechanical pollination the following year on the Smyrna fig by Dr. Gustav Eisen. Attempts were then made to introduce the Blastophaga, but without success, until the United States Department of Agriculture succeeded in establishing the insect in 1899 in the fig-orchard of Geo. C. Rœding, at Fresno, Cal. The principle of the fertilization is that the Blastophaga in its native home in the Mediterranean region breeds naturally in the wild or caprifig. The Smyrna fig does not mature fruit unless the flowers are cross-pollinated by hand methods or through the agency of the Blastophaga, which carries pollen from the male caprifig to the female Smyrna fig, hence both the caprifig and the Blastophaga are necessary in order that the commercial fig bear edible fruit. The results of the introduction of this fig-fertilizing insect have exceeded the most sanguine expectations. In 1900 a large crop of Smyrna figs was raised, dried, and placed on the market, and tests made by experts showed that California figs fully equal the imported product, and that they contain a larger percentage of sugar, a superior flavor, and are cleaner and more attractive in appearance. With this introduction a new horticultural industry of great future value to the country has been established. The United States Department of Agriculture has published much information on this subject, two important papers being Howard's ‘Fig-culture in the United States’ (1900); and Eisen's, ‘The Fig, Its History, Culture and Curing’ (1901).

Figaro, fē′gä-rō, a noted dramatic character, brought by Beaumarchais on the stage in Paris, about 1785, in his two dramas, the 'Barbier de Seville,' and 'Mariage de Figaro.' Since that time, Mozart, Paesiello, Rossini, and others, have made the name celebrated in classic operas; and now the term is frequently used to denote an adroit and cunning accomplice. *Figaro* is also the name of a Paris journal founded 1826 but suspended from 1833–54, when it was revived by Villemessant (q.v.).

Fighting-fish (*Betta pugnax*), a small fish of the climbing perch family (*Anabasidæ*), a native of the southeast of Asia, remarkable for its pugnacious propensities. In Siam these fishes are kept in glass globes for the purpose of fighting, and extravagant gambling takes place on the result. When the fish is quiet its colors are dull, but when irritated it glows with metallic splendor. The king of Siam derives a considerable revenue from the licenses for fish-fights.

Fighting Joe Hooker, a nickname popularly applied to Gen. Joseph Hooker (q.v.).

Fighting Parson, The, a nickname given to William Gannaway Brownlow (q.v.), in reference to the vigorous anti-secession leaders written by him for his newspaper, *The Whig,* of Knoxville, Tenn.

Figig, fē-gēg, a town of considerable importance in Morocco; situated on the east bank of the Wady Zusfava, which separates Algeria from Morocco. Figig is several hundred miles from the seacoast.

Figueras y Moracas, Estanislao, ās-tän-is-lä′o fē-gā′räs ē mō-rä′käs, Spanish statesman: b. Barcelona 13 Nov. 1818; d. Madrid 11 Nov. 1882. He studied law at Madrid and early in life began political activity in the Republican party. He was elected deputy from Barcelona 1851, becoming a leader of his party, but was exiled for participation in the plot against Narvaez for a few months in 1867. After the fall of Queen Isabella he continued to oppose actively the restoration of the monarchy. Upon the abdication of Amadeus in 1873 he became president of the council of ministers, but after the restoration of the monarchy in December 1874, took no further part in public affairs.

Figueras, fē-gā′räs, Spain, town, in a plain 21 miles north-northeast of Gerona. It is defended by a fortress, considered the strongest in Spain. It is large enough to accommodate 20,000 soldiers. It has some manufactures, chief of which are woolen and linen fabrics, leather, soap, corks, etc., and a trade in these and in grain, oil, and liquors. Pop. 11,912.

Figueroa, Francisco de, frän-thēs′kō dā fē-gā-rō′ä, Spanish poet: b. Alcala de Henares 1540; d. 1620. He was called by his contemporaries "the Divine Figueroa," and at Rome he won the poet's crown. He wrote verse with equal facility and elegance in Castilian and Italian. When dying he burned all his verses; but they were published — including the celebrated volumes of eclogues in blank verse, the 'Tirsi' — from copies in the hands of his friends.

Figueroa, Francisco, Mexican annalist: b. Toluca 1730; d. City of Mexico 1800. He was a Franciscan priest and taught and lectured acceptably, but his great service to literature consisted in the compilation of materials for a history of Mexico, among them a 'History of the Conquest of New Galicia,' by Mota Padilla, besides diaries and letters.

Figueroa, Francisco Acuña (ä-koon′yä) **de,** Uruguayan poet: b. Montevideo 1791; d. there 6 Oct. 1862. A civil-service post afforded him leisure to prepare his 'Poetic Mosaic' (1857), a verse collection, and his more notable 'Paraphrases of the Psalms'; and 'The Toraidas,' a series of Paraguayan notes. He has been assigned a high rank by competent European critics; lofty inspiration and sonorous diction being his characteristics, as exemplified in the 'National Hymn of Uruguay.'

Figuier, Guillaume Louis, gē-yōm loo-ē fē-gyā, French scientist: b. Montpellier 15 Feb. 1819; d. Paris 12 Nov. 1894. He was for a time professor in the School of Pharmacy of his native town, and in 1853 was appointed to a post in a similar school at Paris. Among his works are: 'Exposition et Histoire des Principales Découvertes Scientifiques Modernes' (6th ed. 1862); 'Histoire du Merveilleux dans les Temps Modernes' (1859–62); 'L'Alchimie et les Alchimistes'; 'Vies des Savants Illustres depuis l'Antiquité jusqu'au XIX. Siècle' (2d ed. 1875); 'Les Grandes Inventions'; 'Le Tableau de la Nature' (1862–73); 'Le Lendemain de la Mort' (10th ed. 1894); etc. Several of his works have been translated into English, including different sections of the 'Tableau,' such as 'The Mammalia'; 'Birds and Reptiles'; etc.

Figurate Numbers, or **Figurate Series,** in mathematics, a series of numbers which may or do represent some geometrical figure, in relation to which they are always considered, as triangular, pyramidal, hexagonal, etc., numbers. The general term of each series is

$$\frac{n(n+1\,(n+2)\quad.\quad.\quad(n+m)}{1.2.3.4.\quad.\quad.\quad.\quad(m+1)},$$

in which m determines the nature of the series and n is dependent upon the place of the required term of the series. Figurate series are divided into orders: when $m=0$, the series is of the first order; when $m=1$, the series is of the second order; when $m=2$, the series is of the third order, and so on. The figurate series of the first order is the series of the natural numbers, 1, 2, 3, 4, 5 . . . . n. The figurate series of the second order has for its general term $\frac{n(n+1)}{1.2}$, and the several terms are deduced from this by making in succession $n=1$, 2, 3, 4, etc. The resulting series is

$$1,\ 3,\ 6,\ 10,\ 15,\ 21\quad.\quad.\quad.\quad.\quad\frac{n(n+1)}{1.2},$$

etc. The numbers of this series are called triangular numbers, because they express the number of points which may be arranged in triangles, thus:

etc. The series of square numbers is 1, 4, 9, 16, 25, 36, 49, etc. The series of pentagonal numbers is 1, 5, 12, 22, 35, 51, etc.; and of hexagonal numbers 1, 6, 15, 28, 45, 66, etc.

Figure, in arithmetic, a character employed to represent a number. The Arabic figures are 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, by combinations of which any possible number can be represented. (See NOTATION.) In logic, the form of the syllogism with respect to the position of the middle term. In music, a form of melody or accompaniment maintained throughout the phrase in which it is suggested. In a melody, figure is called sequence. In harmony, a figure relates to the rhythmical observance of a certain form in all the accompanying chords to the melody. Also a musical phrase, or a florid melody.

Figured Bass, in music, a bass having the accompanying chords suggested by certain numbers above or below the notes. It is at present the most satisfactory system of musical shorthand. The whole of the notes are not always indicated by a corresponding number of figures, because one number generally implies two or more to complete the chord. When there is no figure, it is understood that the common chord of such a note is to be used as its harmony.

Figured Counterpoint, in music, is where several notes of various lengths, with syncopations and other ornamental lengths are set against the single notes of the canto fermo.

Fiji, fē'jē, or **Viti** (vē'tē) **Islands,** a large group of islands in the South Pacific, situated between lat. 15° 48' S. and 20° 4' S. and between lon. 177° 51' E. and 178° 38' E. There are 255 islands great and small, of which about 80 are inhabited. The uninhabited islands scarcely rise above the level of the sea. Including Rotumah, which belongs to the same jurisdiction, they have an area of 8,045 square miles, of which the main island Viti Levu takes up 4,250 square miles, and Vanua Levu 2,600 square miles. Suva, on the south coast of Viti Levu, is the capital, with a population (European) of 1,073. The whole group is of coral formation, and all the islands seem originally to have formed portions of Viti Levu, some of them probably of Vanua Levu. The conformation of the main island is volcanic and side by side with volcanic deposits are granite, diorite, gabbros and syenite. The silent craters are most numerous in Taviuni. Among valuable metals found in the islands are gold, copper and iron. The islands lie in the track of the monsoons, which blow strongly from April to November, rendering the islands exceedingly healthy; there is an abundant rainfall, and the average temperature for the 12 months is 58° F.; the coldest month (July) has an average of 57°, and the hottest month of 59°. The flora of the Fijis is very like that of the East Indian mainland. Up to the summits of the volcanic peaks stretches a luxuriant growth of tropical vegetation. The forest has little underwood, but abounds in palms, tree ferns, bamboo, and orchids of tree-like dimensions. The fauna belongs to the south Australo-polynesian group; bats and rodents are the only mammals in the islands. There are about 50 species of birds of which the most notable are doves and parrots. The native population is gradually decreasing. The Fijians were once idolators, but since the arrival of English Wesleyan preachers in 1835 they have turned to Christianity. There are 10,402 Roman Catholics in the islands and 103,829 Protestants. There are three newspapers in Suva, and one in Levuka. The principal occupation of the people is agriculture; the sugar, maize and cocoa culture is prosperous, but cotton growing has declined. Tropical fruits are exported to Australia and New Zealand. In 1901 there were in the island 2,455 horses, 24,320 horned cattle, 1,210 sheep, and 14,860 goats. Many herds of swine run wild in the forests. There seems a promising improvement recently noticeable in the prosperity of the islands. In 1901 the total exports, consisting principally of sugar, copra, fruit, distilled spirits, bêche-de-mer, maize and vanilla amounted to $2,744,025, and imports, of which the principal item is under the heading of "drapery," $1,755,910.

The Fiji Islands was constituted a British colony in 1874. The governor is appointed by the crown; he is assisted by an executive council of three; and laws are passed by a legislative council, of which the governor is president. Consult: Cumming, 'At Home in Fiji'; Smythe, 'Report on Fiji Islands'; Seeman, 'Report on the Vegetable Productions and Resources of the Fijian Islands.'

Filament, in botany, the stem of a stamen, supporting the anther. (See FLOWER.) It is usually filiform, but sometimes curiously modified.

Filander, fĭ-lan'dėr, a small kangaroo (*Macropus bruni*), native to New Guinea. It was the first of the kangaroos (q.v.) known to Europeans.

Filangieri, Gaetano, gä-ā-tä'nō fē-län-jā'rē, Italian political economist: b. Naples 18 Aug. 1752; d. 21 July 1788. His great work, entitled, 'The Science of Legislation,' notwithstanding it was never completed according to his original design, attracted great attention, from its bold and original views and the liberality of its sentiments. In 1787 he was made a member of the supreme council of finance.

Filarete, Antonio, or **Antonio Averulino,** än-tō'nē-ō ä-vā-roo-lē'nō fē lä rā'tē, called ANTONIO DE FIRENZE: b. Florence about 1400; d. Rome about 1469. He worked under Ghiberti on the famous baptistery gates. Pope Eugene IV. gave him a commission to make the bronze doors for St. Peters in Rome, and he began their execution with assistants about 1439, finishing them 1445, the whole being a feeble imitation of Ghiberti, in bad taste, and entirely lacking in spontaneity. He also made a bronze reduction of the equestrian statue of Marcus Aurelius for the Capitol, now at Dresden, and a mausoleum of the Cardinal of Portugal which disappeared in the 17th century. He is, however, more noted as an architect. Banished from Rome 1449, on the accusation of stealing relics, he entered the service of the Sforza family at Milan, drawing plans for a great hospital in the antique style, only one wing of which he finished. He is the author of a remarkable book, 'Tratto di Architettura,' written before 1665, a treatise on architecture in 25 volumes, a sort of a verbose and finical romance of which the motive is the construction of an ideal city, called Sforzinda. The undercurrent of the work is a mixture of pagan and Christian philosophy and ethics and an inculcation of didacticism in art.

Filariasis, fil-a-rī'a sis, a group of diseases caused by nematode worms (see NEMATODA) of the genus *Filaria,* some species of which are parasitic in man and domestic animals. The *Filariæ* are very slender worms, mostly parasitic in subdermal connective tissue and in serous cavities. The developmental history is not entirely elucidated, but they seem to undergo indirect development in the body of some crustacean or insect, species of mosquitoes notably serving as intermediary hosts. Under the term *filariæ sanguinis hominis,* old authorities include the species *F. bancrofti, F. diurna,* and *F. perstans,* the last the parasite to which the sleeping-sickness of the negroes in Africa has been attributed. The most important one of these is *F. bancrofti,* whose numerous embryos enter the blood through the lymphatics, and are present at night in the blood, although usually absent in the daytime. This worm (the male) is about 1½ inches long and from 1-10 to 1-12 of an inch broad. The female is almost twice this size. This parasite may be present in the blood without giving rise to any symptoms, but frequently they block the lymph-channels and produce the conditions of elephantiasis. These forms of lymph-scrotum, and of hæmatochyluria, exist very extensively in Asia and Africa, and within recent years have been found in cities in the southern United States. (For lymph-scrotum and elephantiasis, see ELEPHANTIASIS.) In hæmatochyluria the patient, while in excellent health, suddenly passes a large amount of urine of a peculiar whitish or milky-whitish appearance, occasionally bloody; or frequently a fluid resembling chyle, which on settling shows the presence of a blood-clot. This chyluria seems to be intermittent, the patient being well for weeks or months at a time, and then passing large quantities of this modified urine. The embryos are to be found in this urine. Occasionally there are symptoms of uneasiness in the loins and lumbar region, but as a rule the general health is not affected. The treatment is prophylactic solely.

Another form of filariasis is "guinea-worm," a disease produced by *F. medinensis.* It has been known from time immemorial, and it has been fancied that the plague of fiery serpents which afflicted the children of Israel in the wilderness was really an irruption of such worms. This worm is thought to be bred in the body of some minute aquatic crustacean, as *Cyclops,* and thence to enter its final host, which may be the horse, dog, wildcat, or jackal, as well as man, by the drinking of the water. The form of disease brought about by *F. medinensis* is extremely common among African negroes. In certain provinces of India sometimes nearly one-half the entire population are affected; and it is known in Russia, Turkestan, and Hindustan. The adult female worm usually finds its way into the subcutaneous connective tissue, generally in the lower extremities, especially in the feet or ankle. It has also been found in the arm, eyelid, tongue, perineum, scrotum, and trunk. The presence of the worm is not apparent until it bores its way to the skin. Here it produces a painful swelling which later becomes irritable and sore, and finally there develops a suppurating sinus. The worm may be expelled spontaneously from the sore, or it may be taken out in native fashion. *F. loa* is a similar species, limited in its distribution to the west coast of Africa, where it is not uncommon, and is introduced into man by means of drinking-water. It is an active worm, passing rapidly through the connective tissue, and is very frequently found in the region of the eye, where it bores its way to the conjunctival surface.

Consult: Buck, 'Reference Hand-Book Medical Sciences'; article, 'Nematodes'; Manson, 'Tropical Diseases'; Nuttall, 'The Role of Insects, etc., in the Spread of Parasitic Disease'; (Johns Hopkins Hospital Reports, Vol. VIII., No. 1); Braun, 'Thierichen Parasiten' (1902).

Filbert. See HAZLENUT.

Fil'des, Samuel Luke, English portrait and genre painter: b. Lancashire 1844. His first Academy picture was 'Nightfall' (1868), and since then he has exhibited: 'The Loosened Team' (1869); 'The Empty Chair' (1871); 'Fair, Quiet, and Sweet Rest' (1872); 'Simpletons' (1873); 'Applicants for Admission to a Casual Ward' (1874); 'Betty' (1875); 'The Widower' (1876); 'Playmates' (1877); 'The Return of the Penitent' (1879); 'The Village Wedding'; 'Venetian Life'; 'The Al-fresco Toilette'; 'The Doctor' (1892). Several of these, particularly his famed 'Casual Ward,' show powers of realism in painting not unlike those of Dickens in fiction, but his later works are more striking from their color-effects. Latterly he has taken a distinguished place as a painter of portraits. His wife is also known as a painter, some of her pictures being: 'The Cottage Door' (1877); 'Peeling Potatoes' (1878); and 'A Berkshire Cottage' (1878).

File-fishes, the fishes of the plectognath family *Monacanthidæ,* so-called from their skins being roughened by minute rough scales. The species are numerous, small, plain in color, herbivorous, lean and not good for food; and are mainly found in the tropical seas. The best known American species is *Alutera schœpfii,* which ranges as far north as Cape Cod, and often shows a decided orange tint upon its olive-gray sides. It reaches a length of 24 inches, as also does its relative the unicorn-fish (*A. scripta*) of the West Indies. A different and much smaller file-fish is the widely distributed "leather-fish" or "fool-fish" (*Monacanthus hispidus*). The Spanish-American fishermen give the name "lija" to all these fishes. These fishes were formerly classified with the trigger-fishes (q.v.) in the family *Balistidæ,* from which they differ conspicuously in having but one erectile dorsal spine. Consult: Gunther, 'Study of Fishes' (1859); Goode and Bean, 'Oceanic Ichthyology' (1895).

Files and File-making. The file is one of the oldest of hand tools. It is mentioned in the Old Testament scriptures, and probably came into use not very long after man began to work iron. Files were commonly made by hand until about 1850, when machine-made files became general. The first machine proposed for making files was suggested to the French Academy of Sciences in 1702, but it was not until 1812 that the first United States patent on a file-making machine appeared, being taken out by Morris P. Belknap. The files in ordinary uses are made of high-grade steel, from 6 to 14 inches in length being the most common sizes. The pointed end that fits into the wooden handle is called a tang, and the corner formed by the junction of the tang to the body of the file is called the heel. Occasionally they are made with a tang at both ends. The cutting face or faces of a file are formed by the blows of a chisel struck in the file-blank, while the steel is still soft. The closeness and depth of these cuts determines the character of the file, as rough, middle-cut, bastard, second-cut, smooth and dead smooth. When the cuts are crossed so as to form teeth, as in the more common styles, it is a double-cut file. When the spacing between the chisel cuts is varied it is "increment cut." Files are also named from their cross-section, as round (usually tapered, for enlarging holes), half-round, square or flat. Files for sharpening saws take their names from the kind of saw whose teeth they are shaped to fit, as cross-cut file, cant-saw file, pit-saw file, etc. Dentists' files are made with the handle in the centre, and the filing surface on either end. They are styled bicuspid file, plug file, stump file, etc., according to use. A somewhat similar file, only larger, with bent ends, is called a riffler. The files most commonly used by combmakers are called slitting and topper files.

Double or checkering files, used by cutlers, gunmakers, etc., are practically two files riveted together, with the cutting teeth so placed that one is half way ahead of the other. These are used to produce the checkered effect peculiar to gunstocks. The files used by watchmakers are exceedingly small, fine and delicate, many of them being of less section than a fine sewing needle, and about half the length. These are named according to the part of a watch or clock on which they are used, as clock-pinion file, balance-wheel file, barrel-hole file, etc. The file proper is not a rubbing or abrading tool, as many non-technical persons suppose, but a true cutting tool, whose teeth point in one direction, and which can be used effectively only in that direction, that is when pushed away from the user. The horseshoer's rubber and the ordinary rasp are kindred tools that perform their function by being rubbed back and forth, but the file is not intended to be used in that way.

In the case of a rasp, a pointed tool is used to indent the surface of the blank, and this raises prominences on the surface that make it useful as a rubbing or rasping tool. In making files, the blank is first stamped or drop-forged from a high-grade steel, inferior or blistered steel being usable only for rubbers. The file-blank in a soft, unannealed condition, is fixed on the reciprocating carriage of a file-making machine, on a surface of lead designed not to injure the cut side of a file when down. The blank is passed slowly forward under a reciprocating chisel, whose blows descend on the blank at distances determined by the speed at which the carriage moves. In a common type of machine the chisel is moved upward by a cam and thrown down to deliver its blow or cut by a powerful spring. The cuts may be deepened by running the blank through the machine a second time. Old files may be recut in the same way. After the cutting, the file is hardened by tempering, and is then ready for use. In using a file the filer takes the handle in his right hand, with the back of the hand downward. He takes a firm hold of the point with the left hand, placing the thumb or ball of the thumb on top; or he may reverse the hands to rest his muscles. He advances the file, that is, pushes it away from him, with a parallel motion, bearing down as the file goes forward, and brings it back without pressure. The learner always has a tendency to see-saw or rock the file, which can be overcome only by practice. Unless the file is kept level, the surface cannot be cut down to a level. The use of the file in machine work has been much superseded during recent years by the introduction of the emery wheel, operated by power, against which the work is held and ground down with much reduced labor. But the emery wheel will not accomplish a great many things that can be done with the hand file, hence its manufacture is not endangered by the increased use of the wheel. See HARDWARE TRADE IN AMERICA.

Filibusters (Sp. corrupted from Dutch *vrijbuCter*, our "freebooter"), originally the West Indian buccaneers; in the 19th century and now, any lawless band who attack a foreign country not at war with their own. Especially, the United States companies who used to make descents on the Spanish-American states or colonies, either from personal ambition tempted by their anarchic state, or to annex them to the Union as slave territory. Burr's Southwestern Empire was to have been the fruit of the most stupendous filibustering expedition of modern times (1806-7); Texas actually was the fruit of another, disguised as colonization. The later ones, 1850-60, were all of the second type. One of their chief promoters was J. A. Quitman of Mississippi, and in 1850 he aided the adventurer Lopez to fit out abortive expeditions to Cuba, for which both companions were arrested but acquitted. In August 1851 Lopez sailed from New Orleans with 500 men, and landed in Cuba, but the Cubans would not rise. Lopez's force was routed and scattered to the mountains, and he was caught and garroted. Pierce's proclamation of 31 May 1854 showed that the government would tolerate no more of this against Spanish territory; Mexico was too strong to attack privately; and Central America being the only available North American section left, William Walker (q. v.) raised a California company in 1855 and assailed Nicaragua. He defeated the government troops, captured Granada the capital, executed his antagonists and set up a government recognized by Pierce, which re-established slavery and invited Southern immigration. But his performances raised an insurrection, helped by other Central American states, and by a United States corporation he had foolishly plundered, and he was driven out in April 1857. On a second expedition in November, he was seized and brought back; a third was stopped by the government; with a fourth he landed in Honduras 27 June 1860, and was defeated, court-martialed, and shot. There was no more filibustering till after the War; but from 1868 till the Spanish war of 1898 there was more or less, in co-operation with the Cubans. The most noted case was of the Virginius (q.v) in 1873, which the Spanish captured and shot the commander, Fry, with 36 of the crew.

Filibustering enterprises when they meet with failure entail loss of life and of liberty, as well as denunciation from the nation in whose aid they were organized, whereas in case of success filibusters are acclaimed as national heroes.

Among modern filibusters may be mentioned Dr. Jameson (q.v.) and his raiders in South Africa. Had Jameson and his followers been successful in overthrowing the Boer government in 1895, they would doubtless have been hailed as heroes. As it was, their lamentable failure left the English government no alternative but to denounce and treat them as filibusters. After having been condemned to death and to terms of imprisonment by the Boer government, they were eventually turned over to the English authorities for punishment, and taken to trial in London, were convicted and fined and deprived of their liberty.

Perhaps the most noted filibuster in modern times was the Italian patriot Garibaldi (q.v.). In 1862 the Italian government was compelled to arrest him at Aspromonte in order to prevent him from carrying out his project of an armed expedition against the papal states, with which King Victor Emmanuel was then at peace, and in 1867, having managed to evade the watchfulness of the Italian authorities, he actually invaded the papal states, defeating the Pope's troops at Monte Rotonda, being afterward himself routed at Mentana by the French military force that occupied Rome. For this violation of the Italian laws on the subject of filibustering he was arrested by the Italian government after his retreat from Mentana and imprisoned for a time in the fortress of Alessandria. Other modern filibusters were M. De Mayrena, the Parisian clubman and counterpart of Alphonse Daudet's 'Tartarin de Tarascon,' who established himself as King of the Sedangs, and who died as such in his palace in the island of Tio-Man, in the Indo-China Seas, and the Franco-American soldier of fortune and Parisian journalist "Baron" Harden Hickey, who figured for a time as prince and ruler of the island of Trinidad, on the Brazilian coast. See BUCCANEERS; FREEBOOTER; PIRATE.

Filicaia, Vincenzo do, vēn-chen'tzō dā fē-lē-cä'yä, Italian lyric poet: b. Florence 30 Dec. 1642; d. there 25 Sept. 1707. Some of his patriotic sonnets are famous; but his verse, though not without beauty and spirit, is disfigured by the rhetorical tricks and false conceits of the period. An edition of his works appeared at Florence in 1864.

Filigree Glass, one of the kinds of ornamental glass for which Venice was formerly celebrated, the manufacture of which has been recently revived. Small filigree canes of white and colored enamels are drawn, made of the required lengths, arranged in clusters in a cylindrical mold of the required shape, and then fused together. The canes are then aggregated by flint glass at a welding heat, and the mass twisted if a spiral ornament is desired. Vases or other objects are made of ornamental masses of this glass, blown in the usual manner.

Filigree Work, a kind of ornamental work in fine gold or silver wire, wrought delicately, and generally more or less varied by the intermixture of grains or small beads of the metal, and of bands, strips, or bars, to give greater strength. An immense variety of patterns can be produced, the wire being made to assume the forms of arabesques, leaf-work, etc., the parts being joined together by gold or silver solder with the use of the blow-pipe. Working in filigree is one of the most ancient and widely spread arts. Specimens have been obtained from ancient Egyptian, Greek, and Etruscan tombs, and in various parts of Asia articles in filigree have been made from the remotest times down to the present day, as in China and India. In the latter country the wire-work bears much resemblance to the old Greek filigree. An exquisite frosted effect marks the surface of some of the Greek work. After the method of producing this frosting had been lost it was revived or rediscovered. Greek filigree work was especially fine during the 4th or 5th centuries. Among the Celts, Anglo-Saxons, and Scandinavians, excellent specimens of filigree were early produced, being employed in such articles as bracelets, ear-rings, brooches, etc. Old Irish filigree work was of especially high quality, particularly during the 10th and 11th centuries. The Byzantine workers in filigree were also famous, and the influence of their work was widely felt in Europe during the Middle Ages, books, reliquaries, etc., being ornamented in this manner. At Venice, and in several of the French and German towns, elegant specimens of this delicate art were manufactured as early as the 12th century. In the 17th century the art was carried to its highest perfection in Italy. The Italian peasantry, as well as those of other countries, still produce filigree work for personal adornment; and the Malta filigree is world-famous. The Chinese filigree, made mostly of silver, has not the extraordinary delicacy of some of the Malay and other eastern work. Filigree objects of great beauty of workmanship are produced in the United States.

Filioque, fĭl-ĭ-ō'kwē ("and from the Son"), a phrase inserted in the creed of Nicæa, or rather the Nicæo-Constantinopolitan creed, as an expression of the Catholic Church's teaching concerning the relation of the Third Person of the Holy Trinity to the Father and the Son. Before the insertion of *Filioque* that creed, in its Latin version, contained these words, *Et in Spiritum Sanctum . . . . qui ex patre procedit* (and in the Holy Ghost . . . . who proceeds from the Father). The addition of *Filioque* (and from the Son) after *procedit,* appears to have been made first in the churches of Spain as early as 447; it was commanded by the Synod of Toledo 653. But the addition was not adopted or approved by the Roman Church till as late as the 9th century; this, not because the *Filioque* imported into the creed a doctrine not accepted in that Church, but simply because it was not considered wise to add anything to the ancient formula of Catholic belief. The Greek Church never accepted the addition till in the Council of Florence, 1439, the large number of Greek bishops and metropolitans, with the patriarch of Constantinople at their head, who attended that council, solemnly subscribed to the Nicæo-Constantinopolitan *symbolum* as amended by insertion of *Filioque,* and thus effected, as they believed and as the Latin bishops believed, a reunion of the Eastern and Western Churches. At the same time the bishops representing the Latin Church in the same council, signed a solemn declaration that the formula which had been used by the Greeks, "proceeding from the Father *through* the Son" was thoroughly orthodox and consonant with the *Filioque.* The Greek Church itself did not ratify the action of its representatives in the Florence council until 1452, when they were acknowledged and promulgated in the Church of St. Sophia at Constantinople; but in a council held by the Greeks in 1472 the acts of the council of Florence were formally repudiated, and the act of re-union canceled. The two Churches have ever since been separate.

Filipino, fil-ĭ-pē'-nō, a native of the Philippine Islands. The Filipinos form a very mixed population, and seem to represent almost every type of the human race. Some of the tribes have become more or less civilized, others live in the same barbarism as prevailed before the Spanish occupation. In the make-up of the composite Filipino, the darker substratum has been supplied by the Negrito, the Papuan and the African negro. A copper tint has been added by the Malay and Polynesian. This infusion of fierce blood has given to the islanders their fighting qualities. There exist among them certain arts of life, and a skin of a paler hue, inherited from Japanese, Chinese and Cambodian sources. Hamite, Semite and Aryan are each said by ethnologists to contribute some elements to the life, physical, intellectual, and religious, of this strange people, and two centuries of uninterrupted commerce between the archipelago and South America has introduced also a strain of American Indian blood into the Filipino race.

When we come to analyze the tribes, as far as they are at present known to scientific men, it appears that the Indios, the more or less civilized natives of the archipelago, divide themselves naturally into four groups, namely, Tagals, Vicols, Visayas, and Llocanes. The Tagals are palpably the most advanced in the arts of life, and number about a million and a half. Most of them live in the island of Luzon, preferring to settle in the low-lying plains, or near streams and on the seacoast. From Luzon they extend southward, in scattered groups, through Mindoro, Marinduque, and smaller islands farther south. They cultivate the soil, raise large quantities of rice, and are bold and skilful fishermen; and this active industrious life shows itself in their vigorous physique, and powers of endurance. The Tagalog language is more widely spoken than any other Filipino dialect. The Llocanes occupy territory in the extreme northern peninsula of Luzon. They form but a small tribe, and seem to be distinguished from the Tagals merely by the dialect they use. The island of Visaya is wholly occupied by the tribe from which it takes its name, and the Visayas are said to number some two millions and a half and to speak a distinct language which separates them from the other Malayan races of the archipelago. The Vicols number about 400,000 and are scattered over the Camarines peninsula, and occupy also the islands of Catanduanes, Burias, Ticao, and half of the Masbate. In physical type and habits of life they largely resemble the Tagals. The Sulu chain of islands, which stretches between Mindanao and North Borneo, is peopled by the Moros, who are also found on the southwest coasts of Mindanao, and Balabec, as well as on the south coast of Palawan, or Paragua Island. Their original seat was undoubtedly Borneo, from which they have derived their Mohammedan faith, and most of their social usages. They have nothing in common with the peoples farther north and have stoutly resisted all attempts to Christianize them. They were once the fiercest pirates of the archipelago and lived by ravage and robbery. The natives of the northern islands, upon whom they once preyed, as they learned from the Spaniards the use of firearms, and modern methods of warfare, were able successfully to repel the raids of the Moros, whose primitive weapons could not cope with repeating rifles and Gatling guns.

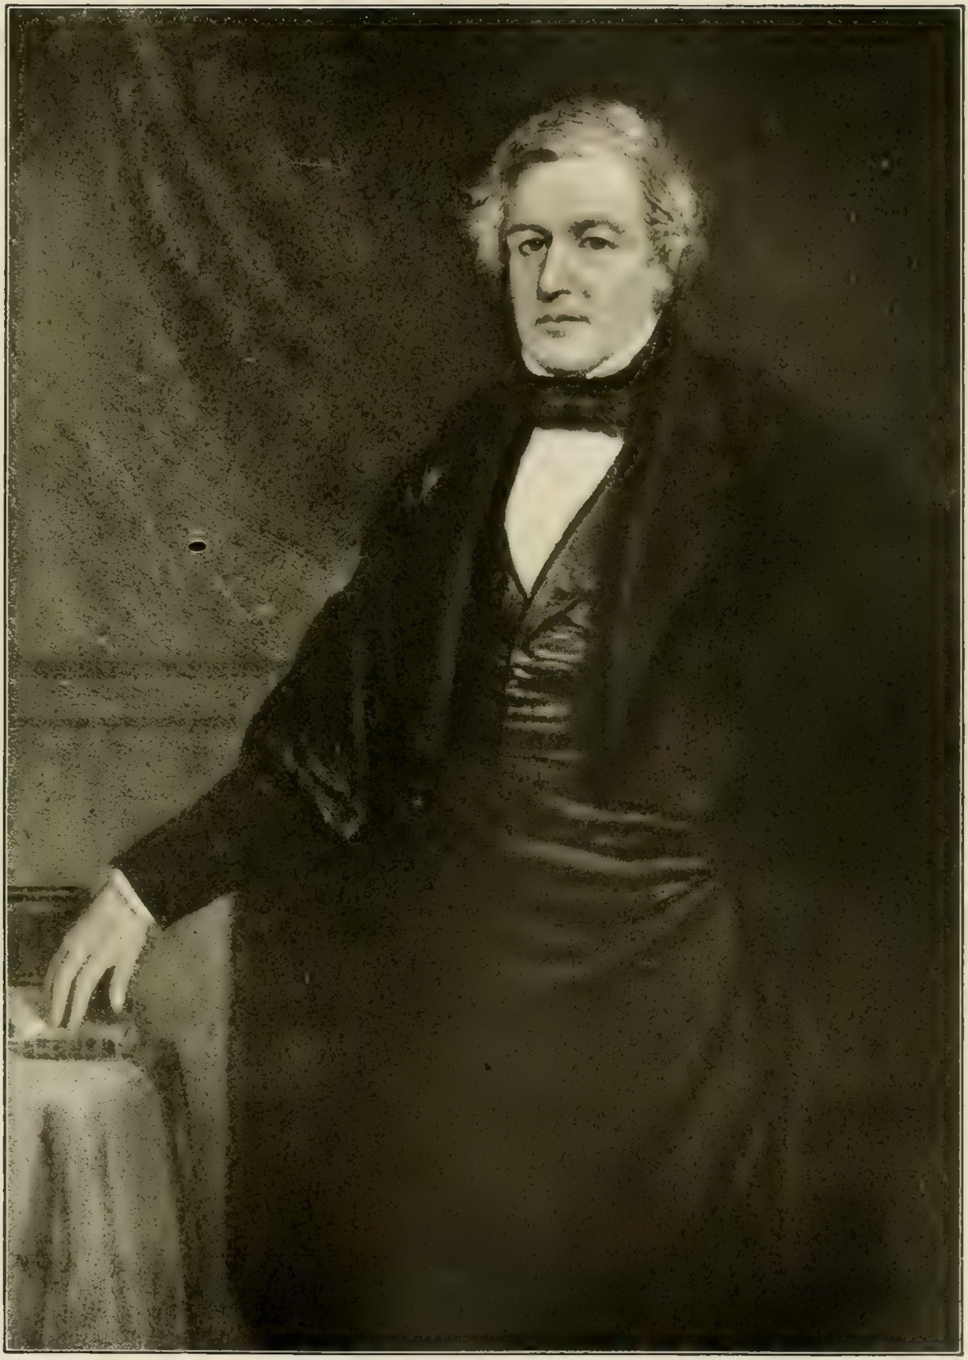
As the mountains are the last refuge of liberty in a conquered country, so also are they the last lurking place of savagery and barbarism. The interior of Luzon and several other islands is mountainous and uncultivated; here lurk the savage tribes whom two hundred years of Spanish rule have failed to civilize or even subdue. These are reckoned at half a million souls, have many languages and dialects, and are in greatest force among the mountain fastnesses of central Mindanao. While some of these tribes are peaceful and inclined to commerce and industry, a large section shows the warlike spirit that urges them to live on rapine. The Negritos, or Little Negroes, dwell in the higher ranges of Luzon and Negro; they are black in skin, and dwarfish in stature; they are evidently a degenerate race, doomed to early extinction.

The Spaniards appear to have done very little to investigate the antiquities of the Filipino races. There is a vast field of exploration open to ethnologists and archæologists in this remarkable archipelago, which possesses a literature of its own in poetry and folk-lore, and has derived from Malay and Indian invaders such arts as metallurgy and weaving, in both of which arts many of the tribes are exceedingly expert. The ethnologists of the Smithsonian Institution have already turned their attention in this direction, and the United States Treasury Department is putting every possible facility in the way of those who are trying to unravel the story of the savage navigators who first cruised in the channels of the Philippine archipelago. See PHILIPPINES.

Filix. See FERN, MALE.

Fillans, James, Scottish sculptor: b. Wilsontown, Lanarkshire, 27 March 1808; d. Glasgow 12 Sept. 1852. After acquiring some local celebrity in Paisley by his portrait-busts, he proceeded to Glasgow. He subsequently visited Paris to improve himself in his art, and in 1836 took up his abode in London. A life-size group in marble, the 'Blind Teaching the Blind,' was exhibited by him in Glasgow, and produced a great sensation. Other admirable works of his are: 'The Boy and Fawn,' a statue of Sir James Shaw (in Kilmarnock), and a bust of Prof. Wilson.

Fillet (1) In ordinary language, a narrow band of metal, linen, or ribbon worn round the head. Sacred fillets were those worn by the priests of Greece and Rome. Also portions of meat or fish removed from the bone and served either flat or rolled together and tied. (2) In architecture, a small flat face or band used principally between moldings to separate them from each other in classical architecture; in the Gothic, Early English, or decorated styles of architecture, it is also used on larger moldings and shafts. Also the projection between the



MILLARD FILLMORE.

THIRTEENTH PRESIDENT OF THE UNITED STATES.

flutes of a column. (3) In anatomy, that part of the sensory nervous tract lying in its passage from the decussation of the sensory columns to the internal capsule. Disease or disturbance of the fillet usually results in a form of generalized anæsthesia. See APOPLEXY; HEMIANÆSTHESIA; HEMIPLEGIA.

Fill'more, Millard, American statesman, 13th President of the United States: b. Summer Hill, Cayuga County, N. Y., 7 Feb. 1800; d. Buffalo 8 March 1874. He studied law in his native county and in 1821 removed to Erie County, and pursued his legal studies in the city of Buffalo. In 1827 he was admitted to the bar and in 1829 commenced his political career as a representative of Erie County in the State legislature, and in 1832 he was elected to the Congressional House of Representatives. For a number of years he alternated between political life and the exclusive practice of his profession, rising steadily in the general estimation as an able lawyer and consistent and promising leader of the Whig party. Elected in 1847 comptroller of the State of New York, he enjoyed in 1848 the still higher honor of being elected by his party as Vice-President of the United States. The new President, Gen. Taylor, entered on his office in March 1849, and on his sudden death in July 1850, Fillmore became, in virtue of his office, President of the United States. He was installed in the White House at what was, in several respects, a critical moment in the history of the Union. It was the era of the Lopez expedition against Cuba; and of a more than usual bitterness in the relations between North and South on the slavery question. Fillmore made Daniel Webster his secretary of state, an appointment which strengthened and popularized his administration. President Fillmore's messages favored the fugitive slave law, and recommended a protective, but not a prohibitory, tariff. Under his presidency California was admitted as a new State into the Union. He was the candidate of the American party for the presidency in 1856, but he received a very small minority of votes. After his retirement from public life he resided in Buffalo, N. Y.

Film, a transparent, flexible substance used as a substitute for glass plates for portable photographic work. It consists of a strip of celluloid which is treated with a sensitized coating, the same as is used on plates (see PHOTOGRAPHY). This strip is wound on rollers, and so placed in the camera that it may be unwound from one roller, exposed, and rolled on another. The film is made from liquid cellulose, formed by dissolving gun-cotton in amylacetate, or other solvent. It can be made in any length desired by stripping the liquid from a polished surface by a revolving wheel.

Fil'mer, SIR **Robert,** English political writer of the Caroline age: d. 1653. He was educated at Trinity College, Cambridge, and became an active Royalist. He wrote in advocacy of the divine right of kings, and was knighted by Charles I. His uncompromising defense of absolution made him a marked man, and his views were strongly controverted by Algernon Sidney and Locke. Undoubtedly his most important work is 'Patriarcha; or the Natural Power of Kings' (1680).

Filmy Ferns. See *Filicales* (7), under FERNS AND FERN ALLIES.

Filon, Auguste, ô-goost fē-lôṅ, French historian: b. Paris, France, 7 June 1800; d. there 1 Dec. 1875. A commanding point of view and alluring style are conspicuous throughout his 'Comparative History of France and England' (1832); 'The Spiritual Power in its Relations with the State' (1844); 'History of the Roman Senate' (1850); 'History of the Athenian Democracy' (1854); and several other important historical works.

Filon, Pierre Marie Augustin, pēār mä-rē ô-goo-stăṅ fē-lôṅ, French critic: b. 1841. He is the son of A. Filon (q.v.), and was tutor of the Prince Imperial 1867–70. He is the literary editor of the 'Revue Bleu' and is the author of 'Guy Paton' (1862); 'Les mariages de Londres' (1875); 'Histoire de la littérature anglaise' (1883); 'Prosper Mérimée' (1894); 'English Profiles.'

Filter and **Filtration.** In chemical technology the process of filtration consists in passing a liquid through a porous or fibrous solid, for the purpose of removing certain elements of the liquid. In chemical analysis in the wet way, filtration is resorted to continually, in order to separate precipitates from the liquids in which they are suspended. The filters used for this purpose consist of sheets of a special kind of bibulous paper, which should consist of almost absolutely pure cellulose, so that it will leave practically no ash when burned. The precipitate, when it has all been deposited upon the filter paper, and has been thoroughly washed, is transferred, together with the paper, to a platinum crucible, in which it is heated until the paper has become entirely burned away, and nothing is left but the precipitate that is to be weighed. Gelatinous precipitates filter very slowly, and for this reason it is usual for chemists to pay careful attention to such little details of manipulation as tend to cause the precipitate to take as granular a form as possible, so that the filtration may be performed rapidly. When the object of the filtration is merely to remove solid particles that are suspended in a liquid, and a quantitative estimate of these solids is not desired other materials than paper are often used as filtering media with advantage. Thus the liquid may be passed through plugs of asbestos fibres, or of glass wool, these particular substances being very useful when the liquid to be filtered is of a corrosive nature, like a strong mineral acid. Filtration through porous plugs is often hastened by creating a partial vacuum on that side of the plug toward which it is desired that the liquid shall flow, and aspirators, or special filter pumps, are constructed for this purpose. When it is desired to remove such minute bodies as bacteria from a liquid in which they are suspended, it is common to pass the liquid through a solid septum of unglazed porcelain, though it has been found that nearly all such bodies can be removed by filtration through a sufficiently thick mass of sand. Cities which must obtain their drinking water from rivers polluted by sewage from other towns and cities are now supplied with water of very good quality by filtering the river water through beds of sand some feet in thickness, and statistics, in such cases, have shown that the installation of such filtration plants is often attended by an almost incredible decrease in the death rate from typhoid fever and other analogous diseases. See WATER PURIFICATION.

Filth-disease, an old term of little scientific meaning at the present time. Modern theories of disease predicate definite infecting agents. Dirt and filth of themselves are not necessarily associated with any known disease. If perchance collections of filth become contaminated with the dejecta of people suffering from infectious diseases, then the filth, through the agency of flies or other insects, may become a source of infection. See CONTAGION; HYGIENE; INFECTION.

Fin de Siecle, făn dē sī-ā'-kl ("the end of the century"), supposed to particularly mark the close of the 19th century, regarded as a period of emancipation from the traditional moral and social state of disorder.

Finance relates to the revenues and expenditures, the pecuniary resources and disbursements of a nation, state, corporation, or individual. It is a word of ancient usage, introduced into England through Normandy, and derived, according to Littré, from an old and now obsolete French verb, *finer*, which was used, in its restricted sense, to signify arriving at a final settlement by payment of money, or finding the ways and means thereto. In Berner's 'Froissart' 1523 occurs the word finance: "So he was put to his fynanse to pay XXII. thousande franks of France and the companyons of the Englysshe garysons in Champaigne payed the sayd ransaume."

The prosperity of nations has often depended on the ability, tact and wisdom of their financial ministers. In France, Colbert and Necker; in England, Godolphin and Peel; in America, Hamilton, Gallatin, and Chase have been regarded as showing eminent ability in finance. The principal object in the study of finance is to arrive at the fundamental principles that should govern the taxes, customs, and income, the credit, loans, and currency, and all that is connected with the revenues and necessary expenditures of a people. This may perhaps be best obtained from the experience of the past as told in history. There we find that practical and sound finance must have due regard to the laws of trade,— which like the laws of nature are never opposed or disregarded with impunity,— that it must insist upon the faithful execution of contracts, and see that taxes are never allowed to injure the source of income. Hume wrote that "one of the chief causes of the destruction of the Roman empire was the alteration which Constantine introduced into the finances, by substituting an universal poll-tax in lieu of almost all the tithes, customs, and excises which formerly composed the revenues of the empire. The people in all the provinces were so oppressed by the publicans (tax-gatherers) that they were glad to take refuge under the conquering arms of the barbarians."

Colonial Finance.— The colonial history of America is replete with interesting problems and experiments in finance. To find ways and means to support the necessary expenses of their respective governments and to carry on the Indian wars was perplexing to all the colonies. Taxation was not a right of sovereignty. The early settlers held and handed down the principle (a principle which Lord Chatham in his speeches in Parliament stated had long been acknowledged in England) that taxes are a voluntary donation from the people to the government. The early settlers declared emphatically that there should be no titles of nobility, no prerogatives, that no man's property should be taken for the public use without his being indemnified. They claimed that every man should bear his portion of the public expenses, but if expenses were incurred for purposes in which the individual and his property were not benefited, for such he could not be taxed. Money was scarce, trade was frequently carried on by barter and it is not, therefore, surprising that the colonies resorted to the issue of paper money. Massachusetts was the first to set the example and the other colonies soon followed, with the result that whatever coins existed in the country disappeared, in obedience to the rule that the poorer currency drives out the richer. Another instructive lesson in the financial history of the colonies was the legislative attempts to fix the prices at which commodities should be bought and sold and labor employed. These regulations were in conflict with the laws of trade and proved futile or disastrous.

Finances of the Revolution.—"The first financial operation of what was to become the United States," was a loan of £6,000 obtained in 1775 by the Continental Congress "for the use of America." Franklin (q.v.) urged that Congress should continue to raise money by loans rather than resort to the issue of paper currency, but the majority of the delegates thought otherwise. "Do you think, gentlemen," cried one, "that I will consent to load my constituents with taxes, when we can send to our printer and get a wagon-load of money, one quire of which will pay for the whole?" The first issue of paper was $3,000,000, and in December 1775 $3,000,000 more were ordered. The certificates or notes were to be redeemed by the States during the four years beginning with 1783.

In December 1777 John Adams (q.v.) wrote to Elbridge Gerry (q.v.), "The man who lent another £100 in gold four years ago and is paid now in paper cannot purchase with it one quarter part in pork, beef, or land of what he could when he lent the gold." Two years later he could not have purchased one thirty-eighth part.

The rapid decline in the value of this currency caused great distress and suffering, reduced many persons from affluence to poverty, and is said to have injuriously affected the moral ideas of the people. After declining from 100 to 1, it ceased in 1781 to pass as money and "barber shops were papered in jest with the bills." The amount of this paper money issued by Congress was stated by Franklin to have been $200,000,000, but Dewey in his recent 'History of the Financial History of the United States' says the total amount issued exceeded $240,000,000. As the bills had been poorly printed, they were easily counterfeited and the counterfeits were so numerous and perfect (some, it is alleged, were manufactured in England) that the redemption of the genuine notes would have been difficult even if the means to redeem them existed.

In the meantime, after other attempts to raise money by appeals to the States and confiscation of the property of Tories with small results, Congress again resorted to loans. In 1783, the loans of the United States amounted to

$42,000,000, of which $7,885,085 were obtained abroad. To meet the interest on foreign loans, money was borrowed in Europe. Home creditors at that time received no interest, and some sold their claims at one tenth of the face value. After the adoption of the Federal Constitution these claims were paid at their full face value by Hamilton.

On 20 Feb. 1781, Robert Morris (q.v.) was made superintendent of finance. He took the office with the stipulation that he should have full power to remove all whom he thought unfit for their positions in the Treasury Department. He began his reform by curtailing expenses and opposing unnecessary expenditures. He introduced system and order, improved the foreign credit, established a bank that was of great service to the government, and when all other sources of income failed, he used his own credit. He remained in office about three years, and for five years thereafter chaos is said to have reigned in the treasury. A decade had not passed after America's experience with continental paper money before France began the issue of *assignats* which had results even more disastrous.

On the organization of the Federal government in 1789, Alexander Hamilton (q.v.) was appointed secretary of the treasury. The public credit was at that time in the lowest state of depression; its fiscal resources were unknown, as no statistical account of the resources of the country had been attempted. He organized the Treasury Department, with a treasurer, comptroller, register, and auditor, and introduced the system of warrants which exists to-day. When he made his first report to Congress and inquired whether he should make it verbally or in writing, they replied that they would receive it in writing, and so all secretaries have submitted written reports. His official reports are considered masterpieces. He established the public credit on a firm basis and retired, after being secretary somewhat more than five years, with the reputation of being one of the greatest financiers of the age.

Among the salient points in American finance is the administration of Albert Gallatin (q.v.). To his suggestion, when he was a member of the House, was due the first formation of the Committee of Ways and Means. Appointed secretary of the treasury by Jefferson in 1801 and continued in office by Madison in 1809, he served the long period of 12 years. He was zealous in the cause of economy and reduced the public debt from $83,000,000 in 1801 to about $50,000,000 when he retired in April 1813, and he had provided funds for the purchase of Louisiana and for the early expenses of the War of 1812. He held that expenses incurred for war should be paid from loans and that taxes should not be imposed except to meet the annual expenses of the government on a peace basis and interest on the public debt, and that the debt would gradually be paid from the surplus revenue caused by the development and growth of the country.

In 1835 the United States stood in the remarkable position of a nation without debt. In that and the following year, nearly $40,000,000 came into the treasury from the sales of public lands. Congress voted to distribute to the States all the surplus over $5,000,000. About $28,000,000 were distributed, but before the balance was paid a severe panic spread over the country; the banks, including those that held the government deposits, suspended, and the government found itself on the verge of bankruptcy. The law authorizing further distribution was repealed.

The law establishing the independent treasury, often called the sub-treasury, was enacted July 1840 and was repealed 13 Aug. 1841. August 1846 the law was re-enacted. The independent treasury now exists with an assistant treasurer in Washington, New York, Boston, Philadelphia, New Orleans, Charleston, St. Louis, Chicago, and San Francisco.

During the panics of 1857 the United States government, having its money in the independent treasury, was able to meet all its obligations promptly and has been enabled in later panics to afford relief to the community by purchase of United States bonds or prepayment of interest. Although sound finance seems to require that the government should interfere the least possible in the affairs and business of the people and that it should not assume paternal functions, there are times when its brief assistance appears justifiable.

Finances of the Civil War.— Salmon P. Chase (q.v.) became secretary of the treasury 7 March 1861. In the beginning it was thought that the War would be of short duration, and when Congress was convened in special session in July 1861 attention was given to obtaining money by loans, rather than by any great increase of taxation. Accordingly, Congress authorized a loan of $250,000,000 in 3-year 7-30 treasury notes and in 20-year bonds with interest not to exceed 7 per cent, or in lieu of a portion of said loan the secretary was authorized to pay salaries or other debts or exchange for coin, non-interest bearing treasury notes payable on demand and receivable for all public dues, to the extent of $50,000,000. Clothed with this authority, Mr. Chase invited representatives from the banks of New York, Boston, and Philadelphia to meet him in New York. The result of the conference was an agreement by the banks of the three cities to advance to the government at once, or as wanted, on the secretary's drafts in favor of the assistant treasurer, $50,000,000 in consideration of which the secretary agreed to appeal to the people for a subscription to a national loan on 3-year notes bearing 7-30 per cent interest, and to pay over the proceeds of the subscriptions to the banks and to make good any deficiency by delivering to them 7-30 notes. The agreement was faithfully fulfilled. Books of subscription to the national loan were opened in all parts of the loyal States and the people responded with enthusiasm and alacrity. About $45,000,000 were thus subscribed and paid to the banks and the remainder was made good by the delivery of the promised 7-30s. This operation enabled the banks to make a second advance of $50,000,000 nearly on the same terms. They attempted to furnish a third $50,000,000 in exchange for the 20-year bonds, but the market price of the bonds declined, the banks were unable to sell them, and 30 Dec. 1861, the banks of New York suspended specie payments and their example was followed throughout the country. On 25 Feb. 1862, Congress authorized the issue of $150,000,000 of legal tender notes. The measure met with great opposition; bankers and members of the boards of trade of different cities hastened to Washington to use their influence against it, and the press very generally denounced it. But the suspension of the banks made it certain that the government could no longer obtain coin on loans. Secretary Chase had wished to avoid the necessity of making notes of any kind a legal tender and with that object had proposed to the banks several plans including a national banking system; but they were slow to give their unanimous consent. As the secretary had not, in any report made by him to Congress, suggested the expediency of making the notes of the United States legal tender, some of the members of the House desired to be assured of his views before voting on the measure; and the Committee of Ways and Means formally asked his opinion as to the necessity and propriety of the immediate passage of the bill. Mr. Chase replied:

> It is not unknown to the Committee that I have felt nor do I wish to conceal that I now feel a great aversion to making anything but coin a legal tender in payment of debts. It has been my anxious wish to avoid the necessity of said legislation. It is, however, at present impossible, in consequence of the large expenditures entailed by the war and the suspension of the banks, to procure sufficient coin for disbursements, and it has therefore become indispensably necessary that we should resort to the issue of United States notes. The making them a legal tender might, however, still be avoided if the willingness manifested by the people generally, by railroad companies and by many of the banking institutions to receive them and pay them as money in all transactions were absolutely or practically universal, but unfortunately there are some persons and some institutions which refuse to receive and pay them and whose action tends not merely to the unnecessary depreciation of the notes, but to establish discriminations in business against those who, in this matter, give a cordial support to the government, and in favor of those who do not. Such discriminations should if possible be prevented and the provision making the notes a legal tender, in a great measure at least, prevents it by putting all citizens in this respect on the same level both of rights and duties.

After the reading of this letter in the House the bill was passed. On 11 July 1862 Congress authorized another issue of $150,000,000, and by acts of 17 January and 3 March 1863 a third issue of $150,000,000, making a total issue of $450,000,000. The issue of these legal tender notes was followed by a great rise in the prices of food and other commodities. Gold went to a premium and fluctuated from day to day. In 1862 $100 in gold sold for $130 in paper, and in 1863 the variations were between $125 and $160. On 17 June 1864 a bill was enacted to prevent speculation in gold. It declared unlawful any contract to purchase or sell gold to be delivered on any day subsequent to that on which the contract was made, or any contract for sale and delivery of gold coin or bullion, of which the person making such contract was not in actual possession at time of making the contract. This legislation, designed to reduce, had the effect of advancing the price of gold. On 17 June gold was selling at $195, by 30 June gold was $250, and 2 July, 15 days after its passage, the law was repealed.

California alone of the loyal States continued throughout the War on a gold basis, her people refusing to accept paper money.

In 1863 the National Bank Act was passed with the beneficial results of establishing a uniform bank currency in place of the currency of State banks, which often circulated with difficulty and at a discount outside the limits of their respective States. As the act required the national banks to hold a certain amount of United States bonds and to pledge United States bonds at Washington as security for the bank circulation, it made an extra demand for the bonds. See BANKS AND BANKING.

In the creation of debt by loans or otherwise, Mr. Chase kept four objects steadily in view: (1) moderate interest; (2) general distribution; (3) future controllability; (4) incidental utility.

At the close of the war Secretary Hugh McCulloch (q.v.) urged the resumption of specie payments, holding that the legal tender acts were only a war measure. In April 1866 Congress authorized the retirement of $10,000,000 within six months, and not more than $4,000,000 any one month thereafter,— $44,000,000 were thus retired when further reduction was suspended by act of 4 Feb. 1868. The legal tender notes thus reduced to $356,000,000 were increased in 1873–4 by Secretary Richardson, who issued $26,000,000 in purchase of bonds. In 1874 Congress passed a bill to increase the amount of legal tender notes to $400,000,000, but President Grant (q.v.) vetoed the bill in his memorable message of 22 April 1874.

Silver Currency.— In the meantime the product of silver mines in the United States was increasing at a remarkable rate. In 1861 the annual product, at its coining value, was $2,000,000; in 1864, $11,000,000; in 1871, $16,000,000; in 1875, $31,700,000; in 1901 it was $71,388,000. The act of 28 Feb. 1878, which became a law notwithstanding the President's veto, authorized the coinage of standard silver dollars and made them legal tender at their nominal value for all debts and dues, public and private, except where otherwise expressly stipulated in the contract, and authorized the holders of silver dollars to deposit the same in sums not less than 10 dollars and to receive therefor silver certificates which shall be receivable for customs, taxes, and all public dues, and when so received may be reissued. The secretary was also directed to purchase silver bullion at the market price, not less than $2,000,000 nor more than $4,000,000 per month and coin the same into silver dollars.

Four years later in 1882 in order to increase the output and circulation of silver dollars, Congress authorized the secretary of the treasury to transport, free of charge, silver coins when requested to do so, provided an equal amount in coin or currency was deposited in the treasury by the applicant.

Under the act of 1878 and prior to 14 July 1890 the

Total amount of bullion purchased was....	$308,199,162
Total dollars coined......................	378,166,793
Seigniorage or gain to U. S. government..	$ 69,967,631

The act of 14 July 1890 authorized the purchase of silver bullion at its market price, at the rate of 4,500,000 ounces per month to be paid for by legal tender treasury notes redeemable "in coin." Said notes when redeemed to be reissued. Upon the demand of the holder of any of these treasury notes, the secretary was directed to redeem these notes in gold or silver at his discretion "it being," so the act reads, "the established policy of the United States to maintain the two metals on a parity with each other upon the present legal ratio or such ratio as may be provided by law."

During the 14 years ended December 1892 $450,000,000 new paper currency ($325,000,000 of silver certificates and $116,000,000 of treasury certificates) had been put in circulation. Under this great volume of currency, the year 1893 commenced with great expectations of increasing business prosperity, but in the spring doubts and distrust spread over the country, people began to hoard gold and one of the greatest panics of the century followed.

To meet the expenditures of the war with Spain in 1898 a loan of $400,000,000 in 3 per cent bonds was authorized by act of 13 June 1898, and a long list of stamp and special taxes imposed, including for the first time in Federal taxation the very un-American tax on legacies.

Of the 3 per cents $100,000,000 were at once issued as a popular loan, directly to the people, preference being given to subscribers of small amounts, $500 or less. The loan was largely over-subscribed and the bonds went immediately to a premium. The war lasted only four months.

The important act 14 March 1900, enacted that the gold dollar of 25.8 grains of gold, 0.9 fine, shall be the standard unit of value, and all forms of money issued or coined by the United States shall be maintained at a parity of value with the standard, and it shall be the duty of the secretary of the treasury to maintain such parity; it also provided that the United States notes and treasury notes issued under act of 14 July 1890 shall be redeemed in gold coin, and authorized a reserve fund of $150,000,000 in gold coin and bullion to be used only for redemption purposes.

The accumulation of moneys in the treasury was in 1903 a matter of much concern to the administration and the secretary, under the sanction of law made a large number of the national banks throughout the country United States depositaries, and there were in August 1903 on deposit in these banks $117,000,000 of United States funds.

The revenues of the government of the United States from all sources (by warrants) for the fiscal year ended 30 June 1902 were:

From internal revenue	$271,880,122.10
From customs	254,444,708.19
From profits on coinage, bullion deposits, etc.	10,979,506.57
From revenues of the District of Columbia	4,217,841.43
From sales of public lands	4,144,122.78
From fees — consular, letters patent, and lands	4,085,229.87
From navy pension, navy hospital, clothing, and deposit funds	2,019,850.25
From Indian labor, sales of Indian lands, etc.	1,775,832.63
From tax on circulation of national banks	1,643,454.73
From payment of interest by Pacific railways	1,564,554.71
From sales of government property	829,314.15
From customs fees, fines, penalties, etc.	828,971.35
From immigrant fund	747,217.15
From miscellaneous	556,153.94
From Soldiers' Home permanent fund	536,045.62
From judicial fees, fines, penalties, etc.	334,233.95
From sales of ordnance material and powder	330,438.53
From deposits for surveying public lands	316,579.23
From sale of naval vessels and army transports	313,948.98
From sale of lands and buildings	272,422.72
From tax on seal skins	231,821.20
From trust funds, Department of State	222,061.94
From depredations on public lands	107,995.58
From license fees, Territory of Alaska	95,805.61
From Postal Service	121,848,047.26
Total receipts	$684,326,280.47

The expenditures for the same period were:

For the civil establishment, including foreign intercourse, public buildings, collecting the revenues, District of Columbia, and other miscellaneous expenses	$111,067,171.39
For the military establishment, including rivers and harbors, forts, arsenals, seacoast defenses, and expenses of the war with Spain and in the Philippines	112,272,216.08
For the naval establishment, including construction of new vessels, machinery, armament, equipment, improvement at navy-yards, and expenses of the war with Spain and in the Philippines	67,803,128.24
For Indian Service	10,049,584.86
For pensions	138,488,559.73
For interest on the public debt	29,108,044.82
For deficiency in postal revenues	2,402,152.52
For Postal Service	121,848,047.26
Total expenditures	$593,038,904.90
Showing a surplus of	$ 91,287,375.57

The changes in the amounts of the several kinds of money of the United States outside the treasury between 1 Nov. 1901 and 1 Nov. 1902 are shown in the table below:

The estimated population of the United States 1 Nov. 1901 was 78,211,000, and the per capita supply of money outside the treasury was $28.72. The estimated population and the per capita supply of money 1 Nov. 1902 were 79,572,000 and $29.36, respectively.

The finance reports of the Treasury Department show receipts and expenditures from the beginning of the government to the present time, and contain much information. From them it appears that the expenditures for the navy did not annually amount to $10,000,000 until 1853. In 1902 they were $67,000,000. The most striking feature in the national expenditures during recent years has been the pensions. In 1875, ten years after the close of the Civil War, the amount of pensions was $29,450,000. The increase was steady till 1890, when they amounted to $87,000,000. In that year a new "dependent pension" law was enacted and they jumped to $107,000,000. In 1893 they reached their highest

THE CHANGES IN THE AMOUNTS OF THE SEVERAL KINDS OF MONEY, ETC.

Classes	In circulation 1 Nov. 1901	In circulation 1 Nov. 1902	Decrease	Increase

point, $159,000,000. In 1902 they were $138,000,000.

Customs have been the main source of revenue. The tariff first enacted in 1789 was simply for revenue, but afterward became also a system of protection to home industries. The total receipts from customs since the organization of the government are over $8,800,000,000 and exceed all other taxes. The amount received from sales of land is $304,000,000.

The ordinary expenditures of the States are comparatively small, limited mainly to legislative expenses, salaries of officers, expenses of the militia, educational and charitable purposes, with extraordinary expenditures for buildings and public works. Palgrave records that in 1890 the six largest States in the Union spent $28,859,010.

Municipal corporations — cities, towns, and villages — have been so extravagant that it has been found necessary in many States to restrict their indebtedness to a percentage (varying under the laws of different States from 3 to 10 per cent) of the taxable property, as determined by the assessors, but excepting from such limitation debts incurred for supplying the inhabitants with water, for manufacturing gas and electricity, and for temporary loans in anticipation of taxes. The tendency of modern times is to increase the exceptions. How far a city or town incorporated for the purpose of providing its citizens with good government should use its revenue in any business for profit-making is a question of the day. Such use makes the citizen and taxpayer, whether so disposed or not, share in the risks, and contribute and pay for any losses, blunders or errors, while he is without redress and claim for damages which the inhabitants would have were the business done under a proper contract with responsible parties.

As there is no uniformity in the accounting systems of different cities, it is difficult to compare their revenues or expenditures. Public interest in their financial reports would be increased were they only based on a uniform system, simple and comprehensive, separating ordinary receipts and payments from the extraordinary, with sufficient detail to show the actual purpose for which the money is expended.

The finances of corporations and individuals have assumed governmental proportions. The recent combination of different companies under one management with a capital of more than a billion of dollars has suggested new ideas of the possibilities of finance when applied to consolidations of business enterprises. The financial transactions between the bankers of the different cities of the world are conducted almost with the facility of local transactions.

The statesman who suggested the protection of a man's property in his inventions through patent laws, must have been one of the most far-sighted of financiers. The great resources of the country are in a large degree the result of inventions made in consequence of those laws. To those inventions are due the agricultural contrivances that have made possible the great harvests of the West; the colossal engines that draw the trains; the mechanical safeguards that facilitate and protect transportation; much of the machinery that enables the mills and manufacturing establishments to compete with the world; the drills that open the mines; the telephone, telegraph, and a vast number of industries throughout the land; all contributing directly and indirectly to the public revenue. And the

great corporations, even the monopolies, are working in the service of the people, for, in the proportion that they satisfy that service, lies their profit. The creation of banks reduced the rate of interest; that of railways the cost of travel; that of great industrial combinations the price of commodities. The greater their service the greater their profit. They are compelled by the unwritten laws of trade to reduce charges to the point that will bring the largest net returns.

A French writer on Finance has with reason stated that no advantage is to be derived from a comparison of the financial systems of America with those of France, nor even in comparing those of the different European countries with each other.

Each nation seeks its prosperity in accordance with its environment and the habits and requirements it has inherited from the past.

It may be interesting, but not very useful, to an American to know that the octroi duties on articles of food and other commodities, collected at the gates of a French city,— a system that has come down from the Middle Ages — amount to much more than half of the ordinary revenue of the city; and it is not apparent that any benefit can come from comparing the relative percentage of the national to the local expenditures of the different countries, although the figures vary greatly; nor in comparing the pensions of foreign nations, frequently, as in Germany and France, paid by employment or minor offices, with the pensions of the United States which are always paid by a treasury check.

The income taxes as levied in England are no longer possible in the United States under the Constitution and the decisions of the Supreme Court. They were tolerated during the great Civil War only as a war measure.

The theories of German Socialists, who would make a government one great industrial corporation, are incompatible with the individual liberty and self-reliant character, with the freedom of industry and of labor inherited by American people. See BANKS AND BANKING; BANKS, SAVINGS; COINAGE; MONEY; TAXATION; TRUST COMPANIES; TREASURY, UNITED STATES.

Finback, a whalebone whale of the genus *Balænoptera,* having the dorsal fin, which in most whales is small or altogether wanting, well-developed. This genus is widely distributed and contains a number of species, which include the largest cetaceans known. The special finback or "finner" of the eastern coast of the United States (*B. musculus*) is from 30 to 70 feet in length. Other species are described elsewhere, as Sibbald's whale, sulphur-bottom, etc. Despite their huge size, finbacks yield so little oil, and such inferior quality of whalebone that they are little sought for.

Finch, Francis Miles, American poet and jurist: b. Ithaca, N. Y., 9 June 1827; d. there, 31 July 1907. He was graduated at Yale; and wrote the well-known lyrics: 'Nathan Hale' and 'The Blue and the Gray,' and a popular college song beginning: 'Floating away like the fountain's spray.'

Finch, one of the small, seed-eating birds, typical of the family *Fringillidæ* (q.v.). The term as now commonly used refers to the smaller, more ornately dressed genera and species, and especially to those generally kept as cage-birds, as the canary, chaffinch, goldfinch, hawfinch, greenfinch (qq.v.), and similar well-known kinds of the Old World. In the United States the name is reserved for the American goldfinch and its greenish relative of the north, the pine-finch; for the purple finch (q.v.), the rosy finches (q.v.) of the genus *Leucosticte;* the house-finch (q.v.) of California; and especially for the small gaudily colored southern birds of the genus *Cyanospiza,* represented in the Northern States by the indigo-bird (q.v.). In these little seed-eaters, such as the nonpareil (*C. ciris*), the lazuli finch (*C. amœna*), and the Mexican varied (*C. versicolor*), the plumage of the male abounds in the richest tints of changeable blue and green, varied by other colors in pleasing contrast. All utter sweet and varied notes, and are prized not only as garden visitors but as cage-birds. The name is also commonly given in the northeastern United States to the "grass-finch," more properly a sparrow (*Poocætes gramineus*), a brown bird which breeds and spends its life in open fields, singing most sweetly at dusk, and easily recognized by the fact that when it takes flight it exhibits a white feather on each side of the tail.

Finch-falcon, one of a genus (*Microhierax*) of tiny falcons, or "falconets," of the East Indies. One, *Microhierax cærulescens,* is found in the Himalayas and Burmese countries. Not one of these little hawks is seven inches in length; they are said to be used by native chiefs for hawking insects and button quails, being thrown from the hand like a ball. They sit solitary on high trees, and, according to native accounts, feed on small birds and insects.

Finck, Henry Theophilus, American musical critic: b. Bethel, Mo., 22 Sept. 1854. He was graduated at Harvard in 1876; and from 1878 to 1881 studied physiological psychology at Berlin, Heidelberg, and Vienna. He is musical critic of the New York Evening *Post.* His works include: 'Wagner and His Works'; 'Romantic Love and Personal Beauty' (1887); 'The Pacific Coast Scenic Tour' (1890); 'Chopin, and Other Musical Essays'; 'Lotos Time in Japan' (1895); 'Spain and Morocco'; 'Paderewski'; 'Primitive Love' (1899); 'Songs and Song Writers' (1900), etc.

Finder, (1) In astronomy, a small telescope fixed to the tube of a larger one, the axes of the two instruments being parallel. The finder has a larger field of view than the principal instrument, and its purpose is to find an object toward which it is desired to direct the larger telescope. (2) As a military term: The finder invented by Lieut. Fiske, of the United States navy, is now being constantly used experimentally and may be called complete. It consists of a telescope mounted high enough to sweep the sea. In front of it is the high stone wall of the fort. Or the finder is placed along shore behind rocks or trees to screen it from the enemy's observation. When the enemy's ship comes within sight the telescope is slowly turned until aimed full at the ship. At the same time the hand moves along, pressing a button, after a certain mechanical method, by which the telescope and the button correspond. As soon as they come within the same focus an electric button, connected with a submarine mine lying in the harbor, is pressed, which blows up the ship.

Finding of Goods. See Lost Property.

Find'lay, Ohio, city, county-seat of Hancock County, Ohio; on the Toledo & O. C., the Lake E. & W., the Ft. W. & W. and other railroads; 44 miles south of Toledo. It is in the heart of the oil and gas fields of Ohio. It contains Findlay College, electric lights, electric railroads, several banks, and numerous daily, weekly, and monthly periodicals. Findlay is widely known on account of its phenomenal yield of natural gas. In November 1888 the Tippecanoe gas well was drilled and yielded 31,000,000 cubic feet of gas per day. In the vicinity are rich beds of clay and large deposits of gravel and sand. There are manufactories of glass, pressed bricks, furniture, wooden implements, nails, and an oil refinery, machine shops, foundries, extensive potteries, and rolling-mills. Pop. (1900) 17,613.

Findlay College, a coeducational institution in Findlay, Ohio; founded in 1882 under the auspices of the Church of God; reported at the close of 1900: Professors and instructors, 12; students, 222; volumes in the library, 1,300.

Fine (probably from Latin *finis*), in English law, formerly signified "an income or a sum of money paid at the entrance of a tenant into his land; a sum paid for the renewal of a lease; and an assurance by matter of record founded on a supposed previously existing right. In every fine which was the compromise of a fictitious suit, and resembled the *transactio* of the Romans, there was a suit supposed, in which the person who was to recover the thing was called the plaintiff, conusee, or recognizee, and the person who parted with the thing the deforceant, conusor, or recognizor. Besides the specific uses above referred to, fine has the signification in general law, in America as well as in Europe, of a pecuniary penalty exacted either in punishment of, or in compensation for, an offense, whether committed against an individual, in contravention of the laws of the community, or against the community itself. Fines in this sense are of very ancient origin, and have been sanctioned by the practice of all nations, ancient and modern, from the lowest to the highest degree of civilization. In the earlier stages of society fines form, for an obvious reason, one of the principal modes of punishment. Prisons and artificial restraints impose a burden on society which it is not yet able to bear, and demand an organization which it has not reached. There remain only fines, corporal chastisements, and death. The last is suited only for the gravest offenses; the second is rendered impracticable in the case of many offenses by the dignity of the offenders; the first in many others by their impecuniosity.

In the most civilized nations of antiquity, Greece and Rome, fines were numerous and frequently excessive. In the early period fines were imposed in cattle, the highest amount of the mulcta or damnum being 2 oxen and 30 sheep. The ancient Germans, being a people who highly valued freedom, admitted hardly any punishment but fines, and their influence extended the use of this penalty among other European nations. A murder was commuted by a payment to the family of the deceased. In the ancient French law fines were divided into two classes, according as they were fixed by law or left to the discretion. This distinction has been abolished since the Revolution by the fixing of maximum and minimum limits for all fines. In England the common law recognizes fines, but does not determine their amount, and this is usually fixed in particular statutes, with a discretion to the judge. The rule in England from an early period, and which was incorporated in Magna Charta, was that no man should be amerced beyond his circumstances and personal estate, leaving to the land owner his land, to the merchant his stock, and to the husbandman his wainage or team and instruments of husbandry.

Fine Arts is the generic term for those arts intended primarily to affect the emotions, such as sculpture, painting, music, etc., as distinguished from the *useful arts* which serve the physical needs of life. Art in general may be defined as the exercise of the creative faculty through some form of material activity controlled and inspired by the intellect. All industries are therefore included under the category of the arts in precisely the degree in which they involve the creative activity of the intellect. The products of the useful arts are designed for purposes external to themselves, to serve the needs of daily life; in other words, they are made to be used. The products of the fine arts, on the other hand, are created for their own sake; they are an end in themselves, or — to be more accurate — they exist for the sake of the emotions they are designed to express and to arouse. A chair, however superbly carved, is a work of useful art, because made primarily to be sat on; but a picture is painted for its own sake, not to be used but to be looked at and to excite pleasurable emotions by its beauty of subject, of drawing, of color; it is a work of fine art. So also a poem or a symphony is produced for the sake of the æsthetic emotions it arouses, not for that of any practical or material use to which it is to be put; it is a work of fine art. The fine arts, then, are those whose appeal is to the æsthetic emotions; and just to the extent in which any work of art does so appeal does it enter within the domain of the fine arts. Painting, sculpture, music and poetry belong obviously in this domain; pottery, weaving, building, metal-working are as obviously useful arts. Architecture stands on the borderland of both domains, being the noblest of the useful arts, and yet, in all those elements in which the architect seeks after pure beauty as distinguished from mere utility or fitness, entering into the field of the fine arts, and summoning painting and sculpture to serve it as sister arts.

Besides these major fine arts, there are certain minor arts which minister to the lower forms of æsthetic pleasure. Dancing belongs in this category, when practised not as a social diversion, but as an artistic sequence of beautiful and rhythmic movements, as in the ancient Greek choral dances, the modern Samoan dances, and the higher forms of the operatic ballet. Fireworks are also a form of fine art, having no other purpose than to delight the æsthetic sense by beautiful combinations of luminous form and color. Landscape gardening is a higher branch of the fine arts, in which we may also include as a subdivision all decorative and artistic water-works such as fountains and artificial cascades.

The industrial arts, again, are divisible into two classes; those in which utility or the consideration of the function of the product predominates, and which are called distinctively the *useful* arts, such as pottery, ironwork or carpentry; and those in which the idea of beauty predominates, and which are called the *decorative* arts, such as carving, embroidery, inlay and mosaic, painting (other than that of easel pictures), stained-glass work and the like. The decorative arts closely approach the fine arts, and there is indeed a wide borderland which is common to both, in which the fine arts, especially painting and sculpture, are employed for the embellishment of structures or of movable objects, losing thus somewhat of their independent *raison d'être*. Into this borderland enter such decorative arts as mosaic, glass-staining and carving, in which the product possesses high artistic value independently of the object or structure to which it is applied. Whether, therefore, a given work belongs among the fine arts or the decorative arts is really a question of how far it has been created for its own sake, and how far its artistic value and merit can be dissociated from the object or structure which it embellishes. Thus the sculptures of the Parthenon pediments, although ostensibly created as decorations for a temple, are really of such surpassing merit as works of sculpture, quite apart from their architectural setting, that they are universally recognized as masterpieces of pure sculpture. On the other hand, the charming figures of nymphs of the Seine carved in low relief by Jean Goujon, in the Fountain of the Innocents of Paris, are so evidently designed for the special places they occupy in that structure and lose so much of their value and significance when detached from it, that they are universally recognized as masterpieces of decorative art.

In the appeal which works of fine art make to the emotions there is nearly always a large element more or less purely intellectual, which must be distinguished from the purely æsthetic quality of the work. Thus a picture represents a scene or an episode; a poem tells a story or extols a religious or moral conception; a statue presents the effigy of a hero, or the embodiment in allegorical form of some abstract conception; a song expresses an idea of love, patriotism or war; a building excites admiration by its bold construction and logical planning. Each of these works addresses itself in these particulars rather to the mind than directly to the feelings. In judging them, therefore, as works of art, we must eliminate the element of purely intellectual satisfaction from our judgment in order to weigh correctly the purely æsthetic excellence of the work. A picture æsthetically beautiful may be uninteresting from the intellectual point of view; still more often does it happen that a picture appeals powerfully to the reason, and even reaches the emotions through the intellect, and is nevertheless totally lacking in æsthetic excellence. Thus a political cartoon or a clever caricature may produce a powerful emotional impression upon the public mind, although execrable as a drawing and destitute of artistic excellence. Its effect is produced by a primary appeal to the intelligence, and the emotions which are aroused as the final but secondary result are the moral and intellectual emotions rather than the æsthetic. The appeal of a work of fine art to the æsthetic emotions — to those emotions which are stirred by beauty, by harmony, rhythm, balance, form and proportion — is a direct appeal. It is often difficult to separate the two classes of emotions and to distinguish between the direct æsthetic effect of a work of art and its indirect appeal to the emotions through the intellect, but the distinction is important in any close analysis or detailed criticism, and the failure to recognize it is the root of many erroneous judgments and criticisms by writers on art. This error is frequent in Ruskin's writings, for instance, where moral and intellectual appreciations often dominate what are advanced as purely æsthetic judgments. (See CRITICISM.)

It does not, however, by any means follow that those are the highest forms of art which appeal most exclusively to the æsthetic sense. Instrumental music, dancing and pyrotechny are the branches of art most completely free from intellectual and non-artistic elements, but they can hardly be classed as the "highest" forms of art. On the contrary, intellectual satisfaction is a natural accompaniment of the pleasure we experience in a work of art; and, other things being equal, the higher the form and grade of the work, the higher will be the intellectual satisfaction experienced. The artist who can at once touch our deepest emotions and appeal to our highest intelligence while he delights our æsthetic sensibilities, has reached a higher plane of art than one whose work makes no such intellectual impression. And while it is true that any philosophical analysis of a work of art and of the impressions it produces must make the distinctions above set forth, it is also true that in the enjoyment of those impressions the spectator seldom or never makes such distinction and is in no wise called upon to do so. The philosophical analysis of art is one thing, the subjective enjoyment of it is another. The total impression it makes is very complex, and not easy to divide into its constituent elements. In general, the highest art is that which makes the deepest impression by reaching and touching the highest as well as the deepest phases of our emotional being, alike through the senses and the intellect; not that whose appeal is most purely and exclusively æsthetic, nor that whose execution and technic are the most finished and perfect.

Principles and Technic.— The underlying principles of all the fine arts are the same; the *application and development* of these principles vary with the art, its medium of expression, the purpose of the work, the personality of the artist, the time and place in which he lives and many other circumstances. The application and development of the underlying principles in a given form of art constitute its *technic;* the shape and direction imposed upon this technic by external conditions of time and place, and the resulting characteristics or habits and manner of design, constitute its *style*. It is of course impossible to lay down in a brief *exposé* like the present article, the laws which are recognized as common to all the arts. We can only observe that they relate to *composition*, which deals with the general plan of the work and the relations of its various parts in that plan or scheme, determining the sequence, balance, proportion and rhythm both of the whole and of its parts; and to *expression* or the manner in which the underlying sentiment, conception or idea of the work is developed and made clear and effective. Thus in every perfect work of art, whether of music, poetry, drama, painting, sculpture or architecture, there should be a fundamental *theme*, a dominant idea or conception which runs through the whole, giving coherence and significance to all its parts. The æsthetic conception is to be distinguished from the *subject* of the work. Thus (for instance) in Millet's 'Angelus' the subject of the painting is two peasants ceasing work for a few moments to pray in the field at the sound of the Angelus. The artistic conception embodied in the treatment of this subject is that of distance, of the soft glow of early evening, of quietude and rest; the picture expresses the dreaminess of gathering twilight by the use of the simplest of themes — two peasant figures outlined against the sky and field — using for this purpose the subject indicated by its title. In giving form to the underlying conception the artist must secure predominant *unity* of character or spirit, *harmony* in the assemblage and relation of all the parts, and such *variety* in details as to avoid the danger of wearisome monotony and secure that pleasurable æsthetic emotion which comes from changes not too rapid or violent. This variety may, and generally should, introduce the element of *contrast*, but discreetly, so as not to destroy the harmony and general unity of the whole. *Proportion* should be just, giving to each part and to the whole suitable relative amounts and dimensions; and the whole work should possess both *rhythm* and *balance*. Balance is equilibrium between features or groups of features, an equilibrium of size, of intensity of color or tone, of importance or of accent; rhythm is the ordered succession of variations of accent or emphasis.

Expression depends, as has already been said, upon many elements — the sentiment or conception to be expressed, the medium of expression, the technical resources of the art, and the personality of the artist being the chief. Music is peculiarly expressive of moods, of emotions apart from definite mental concepts; poetry of lofty moral and spiritual ideas; painting of the beauty of nature as interpreted through the artist's personality; architecture of sublimity, splendor, grace and elegance revealed in the triumph of mind over matter; sculpture of feeling revealed in the form and attitude of living beings. Each art has its own range and capacity for expressing feelings, emotions and definite ideas which it carries over from the mind of the interpreting artist to that of the spectator or listener, so that expression is always measured by impression. In general, if the inquiry be limited to the strictly æsthetic field, what is expressed is not a categorical idea capable of statement as a proposition, but rather an abstract emotion, sentiment, or quality, as of grandeur, elegance, power, sublimity, grace, pathos, or the like. In works of representative art, such as painting and sculpture, fidelity to nature enters largely into this power of expression. This is a different thing from the photographic mimicry of nature which is sometimes admired by undisciplined minds, and which often characterizes the periods of decline in the history of art. This close mimicry is an affair of skilful technic, not of high art. To paint a key hanging on a nail so that the spectator shall mistake it for a real key is clever painting, but little more. A great painting is one which seizes most completely and conveys through the eyes to the soul most effectively the essential truth, the deep underlying aspects of a scene, subordinating to this end whatever details would interfere with the force and completeness of this impression. These aspects and this impression must first exist in and possess the artist's mind: he can put into his work only what he himself possesses; he must be himself inspired if his work is to be inspiring, for a truly great work cannot be produced by accident, nor by an inferior artist. Great works of art may be marked by flawless technical execution, but this perfection of technic is not essential to their greatness. It is, indeed, oftener found in decadent art than in the periods of greatest inspiration; for it is when inspiration flags that technical finish begins to be exalted into the place of first importance.

Style.— It would at first seem as though the works of the artist, who has in all ages sought to clothe his conceptions in the forms that seem to him most suitable and expressive, would in every case be stamped with so personal and individual a character that classification by styles, periods and epochs would be impossible. But as a matter of fact, however various the moods, emotions and conceptions of artists of different races and ages, and however manifold the forms in which they are expressed, the men of any one land or period are in general so conditioned by like circumstances and environment, by similarity of customs, traditions and education, by widely-prevailing ideals and aspirations and even by popular taste and fashion, that they are unconsciously constrained into certain similarities of subject and of manner by which the art of their time and place is clearly distinguishable from that of any other. The social, religious, political and intellectual forces of the age inevitably mould the products of its art, and the resulting predominant manner, form of expression, quality and habit of design we call the *style* of that age and place. The most daringly original artist cannot wholly escape the influence of his environment and education, and those who succeed most completely in disregarding these influences are so few in number that they rarely affect the general set of the art-currents of their day, though they may sometimes prove to be the heralds of new ideas and methods — that is, of a new style — which comes into recognizable existence at a later date. Styles are therefore not mere fashions, nor can they be created or abolished. They are growths, the natural characteristic interpretation of the spirit of the age. The fine arts are therefore rightly studied as the true exponents of the civilizations which produced them. Greek art differs from Roman art as Greek civilization differed from that of Rome. Gothic art differs from that of the Renaissance, French from American art, the art of the end of the 19th century from that of its beginning. The phenomena of style are true of all the arts — of literature and poetry as unmistakably as of music and sculpture, of painting and architecture. It is, however, in the last named art that styles are most clearly distinguished, not only because of the definiteness and permanence of its forms, but also and chiefly because architecture touches the daily life and habits of a people at more points than any other art, and deals with materials and technical processes which of necessity vary widely in different lands and ages. (See ARCHITECTURE.)

History.— A history of the fine arts is really a history of the rise, growth, decay and succession of styles in the various arts, with special mention of those masterpieces which embody in the highest degree the qualities and characteristics of those styles, or which mark the various stages of their development. It is manifestly impossible within the limits of this article even to sketch in outline the historic developments of the several fine arts; for this, the reader is referred to the histories of art mentioned in the bibliography at the close of this article, and to the briefer notices in this encyclopædia under the several titles: ARCHITECTURE; DANCE; DRAMA; MUSIC; PAINTING; POETRY; SCULPTURE. All that can be here attempted is a brief review of the general movement of the fine arts from the earliest beginnings to the present time. Music and poetry, as the subjects of separate treatment in detailed articles will be omitted or only incidentally alluded to in this brief sketch.

Primitive and Savage Art.— The fine arts, properly speaking, have no existence in primitive society. The artistic instinct of man is in the earlier stages of civilization confined to efforts to imitate natural forms, especially human and animal, to which he attributes supernatural powers and which he worships; and to the decoration of his weapons and implements of daily life. Primitive art is therefore primarily symbolic or fetishistic (see ANTHROPOLOGY; FETISH), or else industrial. But in this early art, and particularly in that which has a religious or symbolic character, lie enfolded the germs of a higher development, out of which in a higher stage of civilization come the true fine arts, in which the artist seeks to realize ideals, and the beautiful, sought after for its own sake, begins to take the place of the grotesque and terrible. Very little remains to us of the products of truly primitive mankind, but these few relics, consisting chiefly of chipped flint tools and weapons and engraved or carved ivory and bones, coming down to us from the Stone Age (both palæolithic and neolithic) are of great value as evidence of the observation of nature and of the decorative instinct of the men of preglacial times. The art of modern savage and barbarous tribes is generally treated as exemplifying various stages of the evolution of art from the most primitive beginnings, but it has not yet been demonstrated beyond question that modern savages really offer us a picture of truly primitive conditions. There is much in the life and customs of many savage peoples that is quite as suggestive of degeneracy as of primitive simplicity, and it is next to impossible to find a tribe that has not in some way — direct or indirect — felt the contact of other peoples and been thereby lifted or degraded measurably from its own original status.

Early Oriental Art.— The most ancient works of developed fine art known to us are those of the two great historic cradles of civilization, the valleys of the Nile and of the Tigris-Euphrates. The works which preceded the developed art of those valleys, previous to 4000 or 5000 B.C., are not yet sufficiently known to reveal clearly the stages by which this art grew up from its primitive beginnings, or to prove whether it was indigenous or sprung from roots to be sought in other soil. We know that in each of these valleys a wonderful civilization existed thousands of years before the Christian era, producing works of art of a high order in poetry, in painting and sculpture, and in architecture. That of Egypt was on the whole more advanced than the Chaldæan, especially in sculpture and architecture — for which arts, indeed, it enjoyed the advantage of abundant granite and limestone, syenite and basalt, while the art of the Chaldæans was restricted by the scarcity of stone and even of good timber in the broad, flat basin of the Tigris and Euphrates. Clay and its derivatives — brick, tile and terra-cotta — were the chief resource of the Chaldæan artist, and his libraries of clay-tablets and cylinders, his stupendous palaces of sun-dried brick lined with stucco and enameled tiles, and the skilful use he made of his scanty limestone and alabaster for sculptural decorations and pictures in low relief, show how strong was the artistic instinct of that people. In their pictorial art, displayed in the low-relief of their alabaster slabs, they showed greater fidelity to nature and greater freedom from conventional traditions, than the Egyptians. The foregoing remarks apply equally to the early Chaldæan monarchy and to the great Assyrian empire which finally, about 1200 B.C., overthrew and absorbed it. The art of Egypt was, however, incomparably richer. Its resources were vastly greater, and the pyramids (see PYRAMIDS) and tombs — the chief remaining monuments of the earlier dynasties from the first to the 12th (about 5000–2100 B.C.), the magnificent temples of the later dynasties, and the great relief-pictures and colossal portrait-statues with which they were adorned, are highly impressive examples of fully developed arts. Grandeur, impressive dignity of scale and monumental simplicity of line and mass characterize the temple architecture of the Egyptians and their monumental sculpture; they achieved also remarkable results in portrait sculpture, and the pictures painted in their tombs and carved or engraved as well as painted on their temple walls and columns, give graphic representations of Egyptian life and religious conceptions. The Egyptians also excelled in the decorative and industrial arts, using color in ornament and in pictorial decoration with skill and good taste. Religious conceptions dominated all this art, and symbolism, verging on primitive fetish-magic, pervaded all its manifestations, while its forms of expression were so controlled by hieratic traditions that it never emerged from conventionalism as did Greek art later. Architecture was the one independent art to which the other arts were subservient. In Chaldæo-Assyrian art the religious idea is less exclusively predominant, war and personal luxury dividing with religion the control of the arts. The art of these two great centres — Egypt and Chaldæa — jointly influenced all the early art of the Mediterranean basin; of Crete and later of Rhodes and Cyprus, of the early Greek culture in Mycenæ and Tiryns, of Phœnicia and later of the Persian empire which overthrew both Egypt and Assyria. But in none of these centres was a great art ever developed except in Greece and Persia. In the other centres the decorative and industrial arts are more important than the fine arts; in Persia there was developed in the 6th century an impressive palatial architecture accompanied by remarkable work in decorative relief sculpture, but the style was short-lived and exerted no lasting influence on art in general, passing away with the decline of the Achæmenian dynasty.

Greek Art.—The Aryan Greeks, who migrated from Central Asia in successive waves to Greece, the Ægean islands, southern Italy and Sicily, and the sea-coast provinces of Asia Minor, developed a culture essentially different from that of Egypt or Assyria, less exclusively dominated by religious conceptions than the one, far less inspired by the pursuit after splendor than the other, but animated from the start by the instinctive reaching out after ideals of pure beauty of form. Sculpture early displayed the effort to imitate the perfection of nature, unhampered by conventional restrictions, and in its highest development in the 5th century B.C. gave to the world, in countless statues and reliefs of gods and goddesses, heroes and athletes, superb models of an idealized perfection of human beauty which have never been surpassed and seldom equaled. Greek architecture, serving the gods and the state alike, developed a few simple varieties of the column and entablature (see ARCHITECTURE), into a style of the utmost elegance of proportion and refinement of detail, which continued in use for over five centuries. In this style (for all Greek architecture may be considered as constituting a single style) three forms of columns each with its special entablature, were successively evolved, the Doric, the Ionic and the Corinthian, the first being the most severe, the last the most ornate in character. (See ARCHITECTURE, PARTHENON.) Greek poetry, drama, oratory and prose literature, inspired by a new spirit of inquiry, by the highly-developed civic patriotism of the Greeks, and by their love for perfect rhythm and proportion, reached a nobility of style which has made them the study and in large measure the model of all succeeding ages. We know little of Greek music or of Greek painting, but the highly-developed decorative art of the Greeks, as revealed in their vases, their coins, and whatever else has come down to us of the appurtenances of their daily life, displays everywhere the same pursuit of ideal beauty, the same love of harmony, proportion, balance and rhythm, which we observe in their literature, sculpture and architecture, and which found another medium of expression in their sacred dances.

Greek art in its origins drew freely from Egyptian, Assyrian and Mediterranean art, especially in its decorative motives, but early began to transform the motives and ideas it borrowed, so that it became the most original and creative art of all antiquity, reacting upon later Egyptian art and contributing to Roman art its most vital elements. The age of Pericles, succeeding the Persian wars, was the age of its highest development; during the 4th century (sometimes called the Alexandrian Age), it declined in purity and sought after splendor, sinking thereafter gradually into insignificance. But it came to new life in its inspiration of Roman art, and in some of its provincial manifestations in Syria and the Byzantine empire, after the time of Constantine. See GREEK ART.

Roman Art.—While Greece was declining, Rome was rising to the political-military mastery of the world. The Roman civilization was practical and material rather than artistic and philosophical like the Greek. The Romans were soldiers, organizers and engineers, not artists and theorists. But with the conquest of the Greek states in the 3d and 2d centuries B.C. the Romans began to acquire a taste for the splendors and refinements of Greek art. Greek philosophy and literature were cultivated; Greek statues and bronzes adorned the villas of the wealthy and the fora and public buildings of the capital; Greek artists were employed to copy the great works of Greek sculpture, to carve and decorate and even to design and erect temples and palaces for the Romans. This new Græco-Roman art was, however, entirely unlike the Greek art whose forms it adapted to new purposes. It was inferior to the Greek in every department but one — that of architecture, and in this it differed so radically in principle from the Greek that comparison is hardly possible. The Roman skill in engineering construction and the Roman love for grandeur, for vastness of scale and splendor and for sumptuous beauty of materials, constrained architecture into new paths, resulting in the creation of new and varied types of buildings, in which details borrowed from the Greek columnar style, and often executed by Greek artists, were adapted to new uses in conjunction with the arch and vault which the Greeks had never employed. The spaciousness and imposing splendor of the Roman temples — as exemplified, for instance, in the still extant and superb temple known as the Pantheon (q.v.), built about 124 A.D. — and of their baths, amphitheatres and basilicas, were such as had never before been realized in any land or age. The decorative arts of carving and mosaic, of stucco-relief ornament and marble incrustation, as applied to architecture — we might almost say the whole art of architectural decoration as distinguished from pictorial painting and sculpture applied to buildings — were first developed systematically by the Romans. To the three Greek "orders" of architecture — the Doric, Ionic and Corinthian — which they adopted and modified, they added two others: the Tuscan, a survival of the rather primitive Etruscan form of column, and the Composite, a variant of the Corinthian. Roman sculpture was inferior, attaining little distinction except in some of the imperial portrait-statues and busts. Painting was more highly developed and, although practised chiefly as a decorative art and by Greek artists, as shown by the ruins of Pompeii (q.v.) and Herculaneum, produced in various parts of the empire works of portraiture and of ideal representation of a high order. (See PAINTING.)

Early Christian and Byzantine Art.— The age of Constantine (330 A.D.) witnessed a great transformation, not only in the political organization, but also in the religion and art of the civilized world. Christianity, triumphing over three centuries of proscription and persecution, was recognized as the religion of the empire, and Roman art, which had shared in the decline of the imperial power, found a new field in the service of this religion. In all the symbolism of Early Christian Art we trace the survival of pagan Roman symbols invested now with new meanings, and the architectural types of the Roman basilicas and tombs were modified for the building of Christian churches and baptisteries. Sculpture suffered for centuries from the proscription which resulted from its association, in the mind of the early Church, with pagan deities and idol-worship; but painting took on new life in the service of the Church, especially in the derivative form of mosaic (see MOSAIC) and in the illumination of ecclesiastical manuscripts. The field of the arts was a narrow one, and none of them rose to very high or independent development except in the Byzantine empire. Here, especially in Constantinople (which, after the fall of Rome before the Goths in 476 became, and for a considerable time remained, the most enlightened, prosperous and conspicuous city in Christendom) (see CONSTANTINOPLE), the arts flourished; architecture developed new forms and applications of the vault and especially of the dome (see DOME), and produced in the great church of the Divine Wisdom (ἡ Ἁγία Σοφία, commonly called Santa Sophia) at Constantinople (532–38) a stupendous masterpiece, never surpassed in its way. Byzantine architects, mosaic-workers, decorators and manuscript-illuminators were in demand throughout the Christian world of the 6th to the 11th centuries; the superb church of St. Mark at Venice (about 1070 A.D.) is one monument of their employment in foreign lands, and Ravenna is full of Byzantine art. The highly decorative though conventional ecclesiastical style of painting of the Byzantines, dominated by the types of face, figure and symbolism employed in the mosaics, frescoes and altar-pieces of their churches, was carried not only into Greece, Russia and the Balkan provinces, where it has survived to this day, but also into Italy, Germany and southern France, as we shall see later. In Syria there grew up, concurrently with the earlier Byzantine style a strong local school of architecture which has left impressive ruins, quite distinct in style alike from the Byzantine and Roman.

Moslem Styles.— During the Dark Ages which succeeded the fall of Rome, the lamp of culture burned brightest in Constantinople and in the Moslem states. The Arabs had extended their conquests during the 7th and 8th centuries over Syria and Persia, northern Africa, Spain and Sicily. Destitute themselves, at the outset, of artistic culture, they rapidly absorbed that of the nations they conquered, and the experience of Rome in the conquest of the Greek states was repeated. The new art that grew up was wholly different in spirit and detail from that of any of the conquered peoples, although largely executed by artists from their ranks. It was applied to different uses and expressed a different order of ideas and sentiments. The Moslem hatred of idolatry led to an almost absolute proscription of painting and sculpture and this restriction upon two of the highest forms of artistic expression may in part account for the extraordinary development in their stead, of the decorative arts in Moslem lands. These, without the all-pervading symbolism of ancient Egyptian art, reached a very high power of expression or suggestion of moods and feelings which — if we may believe some students of these arts — raises them almost to the plane of music and places them clearly among the fine arts. Unlike western art, in which *form* has always been paramount, Moslem art, like all Asiatic art, excels in the treatment of *color*. The Persians were the only Moslems to develop the art of painting, and with them it was practised chiefly in the form of miniature pictures and manuscript illustration, in which — as in the semi-naturalistic floral decorations of their tiles and fabrics, they showed considerable observation of nature. In architecture the Moslems have always excelled on the decorative side, and the buildings of the Arabs and Moors seldom display boldness of construction or largeness of scale. In Turkey, however, where Byzantine models were followed, and in Persia and India, where the Aryan element is dominant, the Mohammedan mosques, tombs and gates are often of imposing grandeur of scale and admirable in structural design.

Mediæval Art.— Meanwhile as Europe emerged slowly from the chaos and barbarism of the Dark Ages, with the development of new nationalities, chiefly Celtic and Germanic, a new Christian civilization and new art were taking shape, dominated by the Church of Rome, whose institutions, both monastic and hierarchic, were established throughout all Europe except the Byzantine empire, where the Greek rite prevailed. The Church absorbed all activities not occupied in the warfare of feudalism, and the arts were practised almost wholly in her service. The centuries from the 5th to the 11th were the Dark Ages when throughout northern, central and western Europe chaos and ignorance were universal; but with the dawn of the 11th century order began to emerge from the chaos, and the wealth and power of the monastic orders began to show themselves in the building of great abbey-churches and monasteries, as well as in the copying of manuscripts and the study and teaching of the narrow scholasticism of the Church. In some places — notably in France — the episcopal authority was hostile to that of the monasteries; but elsewhere the two were in harmony, and between them they developed a very active and prolific architecture of abbeys, cathedrals, churches, monasteries and hospitals, at first crude, powerful, massive (see ROMANESQUE ART); later developing its structural system experimentally along logical lines, towards greater loftiness, lightness, elegance, refinement of detail and splendor of decoration, the ribbed vault, pointed arch and flying buttress being the characteristic features of this system; stone window-tracery, stained-glass windows, lofty spires and pinnacles, and a marvelous wealth of symbolic and grotesque and floral carving, the leading elements in the decorative dress of this architecture. The earlier massive style is called the *Romanesque;* the later, completely developed style the *Gothic* (about 1160–1500). As sculpture had been the mistress art of Greece, so was architecture that of the Middle Ages; painting and sculpture wrought chiefly in her service. Yet the sculpture of the Middle Ages, although chiefly executed for the decoration of churches is — especially in France — so important for its own sake, so intrinsically noble and beautiful, as to claim with justice an independent rank. Painting, however, remained a subordinate art, formally decorative and adhering in great measure to Byzantine traditions (see above). For decorative work, for mural painting, which only in the 14th century, in Italy, began to cast off the fetters of this tradition (see CIMABUE; GIOTTO; PAINTING). And for stained glass in large windows, this formal and conventional style served well; but it stood in the way of any independent progress in painting. Architecture first, and sculpture in the second place, were the great arts of the Middle Ages; but poetry and the drama were also practised. War and chivalry were the chief inspiration of poetry, although a few truly noble hymns were born of the religious consciousness of the Middle Ages: the drama existed chiefly in the form of "miracle-plays," "mysteries," and "moralities," of minor importance as literature, although interesting as the germ of the great dramatic art of the Renaissance.

Renaissance Art.— The conspicuous characteristics of the mediæval Christian world may be summed up in a few words as follows: War and religion were the controlling forces, the feudal system and the Church the institutions through which these worked; obedience to authority the universal rule of life. Under these conditions the individual was submerged in the mass, and only under the pressure of external authority. But this condition could not last forever. The love of personal liberty, the longing for self-expression, though long repressed, were not extinct nd began to assert themselves with increasing earnestness and effectiveness, in proportion as civilization advanced, and external authority ceased to be the only synonym of protection and safety for the individual. Independence first began to develop by the introduction of the idea of voluntary obedience to an authority constituted by those subject to it, in the place of involuntary and compulsory subjection to powers claiming authority directly from God or from some other mysterious and external source. This new conception appeared in the industrial and artistic guilds of many mediæval cities; in many "free towns" which claimed certain immunities and privileges as direct inheritances from Roman times and exercised and regulated these through elective governing bodies chosen by the burghers; and in the free republics of Italy, like Florence and Venice. Through the 14th century this idea was germinating, especially in Italy, where it received a powerful stimulus from the revival of the study of the classics, which kindled admiration for the freedom of classic culture and for the beauty of classic art and literature, and aroused a new spirit of secular study, research, and inquiry. This led to the Humanist movement, which was on the one hand a movement for individual culture and on the other a movement of protest against the narrowness and asceticism of ecclesiastical authority. Not only the dictates but the very foundations of authority began to be questioned. Men began to reach out into new fields of thought, to explore nature and antiquity alike, and the beginnings of modern science are to be traced back to this new spirit of independent investigation. This revival of classic learning, this intellectual awakening, is known as the Renaissance — the new birth of free thought and individual culture. The fine arts soon felt its influence. In painting, the study of nature, the pursuit of ideal instead of conventional types, broke the long dominion of the Byzantine ecclesiastical traditions. The Florentine and Siennese schools inaugurated the triumphant course of Italian painting, which led from Cimabue and the great innovator Giotto finally to the superb masterpieces of Raphael, DaVinci, Michelangelo, Titian, Veronese, and Tintoretto. In this triumphal progress of the art of painting it rose from a subordinate ecclesiastical decorative art to the leading position among the arts, the invention or discovery of the process of painting in oils (see PAINTING; VAN EYCK) being a potent contributory factor in this progress. Sculpture had already in the works of Niccolò Pisano (q.v.) felt the inspiration of the study of classic models, but its development was less important than that of either painting or architecture. It remained long subordinate to the latter, although within this relatively limited field many of its products, especially in Italy and France, were of a very high order and some of them unsurpassed. It did not, however, attain complete independence until Michelangelo (q.v.) in the 16th century, made it the medium of expression of his mighty conceptions, rivaling in power and grandeur, if not also in beauty, the noblest masterpieces of Greek art.

Architecture underwent a complete revolution. The Gothic style had never been in Italy anything but a foreign importation, an imitation of French and German details with no assimilation of the structural ideas on which the Gothic style was based. With the new passion for classic study, architecture was on its decorative side made a medium for the expression of this taste by the adoption and imitation of the decorative details of classic Roman ruins. The secularizing tendency of the age and the rapidly growing love of personal luxury, led to the building of palaces, villas and stately gardens, and to the erection of tombs of pompous and imposing magnificence, while churches were built with barrel-vaults and domes in place of the ribbed vaults of Gothic design, and were adorned with the columns, pilasters, and entablatures of the Roman orders, with Roman scrolls, arabesques and arcades. The lofty dome, crowned with a lantern and borne on a high drum encircled with columns and pilasters, became a feature of the later churches, and St. Peter's (q.v.) at Rome, the largest of all churches, embodies in the most magnificent fashion this new type (1503–1629). In all the arts of the Renaissance it is the artist as an individual that claims our attention; although we class the works of the Renaissance by schools and periods — because even individuals feel the constraint of their environment — the personal element is always conspicuous in a manner unknown in mediæval art, in which relatively few names of artists have come down to us.

Poetry and literature felt with the other arts the transforming influence of the classic revival, not only as to form but also as to subject-matter. The drama outgrew the naïve puerilities of the miracle-plays and took on the dignity of an independent fine art, reaching its highest development in the Elizabethan and particularly the Shakespearian drama at the close of the 16th century.

The movement of the Renaissance spread from Italy to the north and west, but found — so far as art was concerned — in France, Germany, Great Britain, and the Low Countries the Gothic style so highly developed and so firmly intrenched that the transformation of taste and of style was very gradual in these countries. In France the Renaissance in art was inaugurated by Italian artists imported by Charles VIII., Louis XII., and Francis I. after their several campaigns in Italy between 1483 and 1525, and manifested itself first in the châteaux and in the tombs of royal and princely or noble families, but the style was very far from resembling the Italian. It was not till the reign of Louis XIV. (1645–1715) that architecture, sculpture, and painting took on the Italian Palladian (see PALLADIO) or classic character in any marked degree. There was constant strife between the distinctively French and classic elements. In Germany and England the Italian manner was even later in asserting itself; throughout the 16th and much of the 17th century the persistence of local, national, and mediæval conceptions and forms resulted in great variety and picturesqueness in architecture, the final disappearance of which in the 18th century was hardly compensated for by the more stately but less original formally classic style that replaced it. Sculpture hardly flourished outside of France, but painting developed in Germany and the Netherlands three important schools in the 16th and 17th centuries — the German, the Flemish, and the Dutch, whose most celebrated representatives were respectively — among many others almost equally famed — Hans Holbein the Younger, Rubens, and Rembrandt. A strong Spanish school also grew up, and in England in the 18th century portraiture and landscape-painting reached a high level. But meanwhile architecture was declining in power and originality; sham and pretense, pomp and affectation were taking possession of society, and taste was corrupted at the fountain-head. The first third of the 19th century — indeed the first half — was a period of artistic poverty and destitution, in all the arts and throughout the civilized world. From this deplorable condition the arts have risen under the impulsion of new forces, social, intellectual and economic, due to the extraordinary changes and the marvelous progress of the last 50 years.

Bibliography.—The bibliography of the fine arts is enormous; only a few of the most familiar and available works can be here specified. The reader is advised to consult Ile's 'Bibliography of the Fine Arts.' Among general hand-books: Lübke, 'History of Art' (in German or in English); 'College Text-books on the History of Art,' edited by Prof. J. C. Van Dyke ('Architecture' by Hamlin; 'Painting' by Van Dyke; 'Sculpture' by Marquand and Frothingham); Kugler, 'Hand-book on Architecture' (German or English); Statham, 'Architecture for General Readers'; 'Modern Architecture'; Fergusson, 'History of Architecture in all Countries'; 'Indian and Eastern Architecture'; 'Modern Architecture'; Fletcher, 'A History of Architecture'; Mitchell, 'Ancient Sculpture'; other books on ancient sculpture by Murray and by Perry; Gardner, 'Greek Sculpture'; Perkins, 'Italian Sculptors'; 'Tuscan Sculptors'; Marshall, Eidlitz, Raymond, Ruskin, Viollet-le-Duc, on æsthetics and art criticism, works by Hegel. On painting works almost innumerable: there exists no one general history of painting of important dimensions (note Van Dyke as above), but numerous books on special schools and epochs: *cf.* Champlin, 'Cyclopædia of Painters and Painting.'

A. D. F. HAMLIN,
Adjunct Professor of Architecture, Columbia University, New York.

Finfoot, one of the extraordinary tropical birds of the family *Heliornithidæ,* now considered near allies of the rails, so called on account of the broad scalloped webs along each toe. The best known one is *Heliornis fulica* of northeastern South America, which is about 13 inches long, and mainly brown, with a white throat, red bill, and feet banded with yellow and black. Other larger species belong to Africa and the Malayan Peninsula. These birds, which frequent the swamps or rocky streams of inland woods, fly heavily, and push themselves out of the water with their feet. They swim and dive well, and run swiftly on land.

Fingal, fing-gal, a once popular epic by James Macpherson, which appeared in 1762. The poet being a favorite, 'Fingal' had an immense sale. The subject of the epic is the invasion of Ireland by Swaran, king of Lochlin, Denmark, during the reign of Cormac II., and its deliverance by the aid of the father of Ossian, King Fingal of Morven, on the northwest coast of Scotland. The poem opens with the overthrow of Cathullin, general of the Irish forces, and concludes with the return of Swaran to his own land. See OSSIAN; MACPHERSON, JAMES.

Fingal's Cave, a curious cavern formed of basaltic columns, in the Isle of Staffa, one of the Hebrides, on the west coast of Scotland, 25 miles from Oban. See STAFFA.

Finger. See HAND.

Finger-grass, a crab grass (*Panicum sanguinale,* Linn.), a well-known annual, common in nearly all parts of the United States, growing in cultivated fields and about dwellings. It is a weed in gardens and among hoed crops. In grain fields after harvest it frequently springs up in such quantity, particularly in the Southern States, as to yield one or even two good cuttings of hay. This spontaneous growth affords excellent pasturage, as well as hay of first quality if properly cured. The stems are much branched, and in good soil attain a length of 3 to 4 feet. This grass contains little fibre, and dries quickly when cut, but if after cutting it is wet by rains or heavy dews its value for hay is almost wholly destroyed.

Finger Notation, a method of representing numbers by the position of the fingers or hands, analogous to the digital language of deaf mutes. The system is an ancient one and has had three distinct ramifications: (1) The obsolete one of mere numerical representation, to retain the numbers erased during operations on the sand abacus, and probably on the other forms as well (see ABACUS); (2) the one leading to a kind of international language, helpful in bargaining at the great fairs of antiquity and the Middle Ages, and still used in the East; (3) that of actual computation, the so-called finger reckoning, still somewhat used in certain parts of the world. Of these three the first was the most important, and with the second it resulted in a number language quite as international as the Hindu-Arabic numerals (see NUMERALS) which led to its decay. The antiquity of the system in Egypt, Greece, and Rome is attested by several classical writers, Juvenal, for example, speaking of the aged Nestor as numbering his years upon his right hand, that being the one used for numerals exceeding 99. Herodotus, Pliny, Macrobius, Plautus, Seneca, Suetonius, and probably Aristophanes and Solomon (Proverbs iii. 16) are among the other witnesses to its use among the common people in ancient times. In the early centuries of the Christian era it was well known, for it is mentioned by Tertullian (c. 200 A.D.), St. Ambrose (c. 375 A.D.), and St. Augustine (c. 400 A.D.). To the Venerable Bede, however, we are indebted for our most definite knowledge of the mediæval system in the West, and to his treatise, 'De loquela per gestum digitorum,' in his 'Opera omnia,' (Paris 1862, tomus I., p. 689), the student should refer for the best description extant. The same notation, not so fully explained, appears in a work written about 800 A.D., although assigned to Cyril of Alexandria ('Liber de computo S. Cyrilli Alexandrini,' published by L. A. Muratori in his 'Anecdota,' Napoli 1776), and in one by Radulph of Laon, c. 1100 A.D. (consult 'Abhandlungen zur Geschichte der Mathematik,' Bd. V., p. 91). The international character of the system is further evident from two poems, one in Arabic (Marre, 'Manière de compter des anciens avec les doigts des mains, d' après un petit poëme inédit arabe de Chems-Eddin el Mossouli,' in the Boncompagni 'Bulletino,' t. I., p. 309), and the other in Hebrew, by Samuel ibn Abbas (Steinschneider, 'Die Mathematik bei den Juden,' in the 'Bibliotheca Mathematica,' Ser. II., Vol. X., p. 81), and from a description by Nicholas Rhabdas of Smyrna. In his 'Epistles on Arithmetic,' written about 1341, Rhabdas gives the digital notation as it had probably been used in Asia Minor for many centuries, and, aside from Bede's description, this is our best source of information. For a brief digest, consult Gow, 'History of Greek Mathematics' (Cambridge 1884, p. 24). For the Greek text, with French translation by Tannery, consult 'Notices et extraits des manuscrits de la Bibliothèque nationale,' t. 32, p. 147 (Paris 1886). The system had not yet died out in Europe when printing was invented, and Paciuolo (q.v.) sets it forth in a page of illustrations in the first great modern treatise on mathematics ('Sūma de Arithmetica Geometria Proportioni & Proportionalita' . . . vinegia . . . . M.cccc.lxliiij, fol. 36, v.). Several arithmeticians of the 16th century gave descriptions of the method, including Recorde (q.v.), the author of the first arithmetic printed in English. The accompanying illustration is from the most elaborate treatise on the subject, that of Aventinus ('Abacvs at qve vetvssissima, vetervm latinorum per digitos manusq numerandi (quin etaim loquendi) cosuetudo, Ex beda cu picturis et imaginabus . . . Ratispone . . . 1532), a work enough esteemed to warrant an edition as late as 1710.

The most common form of finger reckoning was that involving multiplication, the factors being between 5 and 10, thus rendering the table beyond 5×10 superfluous. This form is very old, and is not yet obsolete. For example, to multiply 9 by 8, think: 5 and 4 are 9 (raising 4 fingers on one hand); 5 and 3 are 8 (raising 3 on the other hand); $4 + 3$ (raised fingers) = 7 tens; 1×2 (bent fingers) = 2 units; $70 + 2 = 72$.

In addition to the sources above cited, consult: Stoy, 'Zur Geschichte des Rechenunterrichtes,' dissertation (Jena 1876); Treutlein, in the 'Abhandlungen zur Geschichte der Mathematik,' Bd. I., p. 21; Bombelli, 'L' antica numerazione Italica' (Roma 1876, p. 102); Günther, 'Geschichte des mathematischen Unterrichts im deutschen Mittelalter' (Berlin 1887, p. 12), and 'Untersuchungen zur Geschichte der mathematischen Wissenschaften' (Leipzig 1876).

DAVID EUGENE SMITH,
Professor of Mathematics, Teachers College, Columbia University, New York.

Finisterre, Cape. See CAPE FINISTERRE.

Fink, Louis Maria, American Roman Catholic prelate: b. Triftersberg, Bavaria, 1834. He came to the United States in 1852, was ordained priest 1857, and was successively stationed at Bellefonte, Pa.; Newark, N. J.; Covington, Ky.; and Chicago. Later he became prior of the Benedictine monastery, Leavenworth, Kansas, and vicar-general of that State. He was appointed Bishop of Leavenworth 1871.

Finland, Grand Duchy of (called by the natives, Suomen-maa, "land of marshes"), a country of northern Europe, including, with the exception of part of Lapland, the extreme northwestern portion of the Russian empire; bounded on the north by Russian Lapland; east by the provinces of Archangel and Olonetz; south by Lake Ladoga, the province of St. Petersburg, and the Gulf of Finland; and west by Sweden and the Gulf of Bothnia; length, 600 miles; average breadth, about 240 miles; area, 144,255 square miles.

Topography.— Finland, which is divided into 8 provinces, consists principally of a tableland from 400 to 600 feet above the level of the sea, and interspersed with hills of no great elevation. In the north, however, the Manselka Mountains have an average height of between 3,000 and 4,000 feet. The coasts, particularly on the south, are surrounded by a vast number of rocky islets, separated from the mainland and from each other by intricate and narrow channels, rendering the shores of the country easy of defense in case of hostile attack by sea. The chief natural feature of Finland is its many lakes, which extend like a network over a large proportion of its surface; some of them being of very considerable size. The greater number of these are in the south and east; several of them have intercommunication and generally abound with islands. There are numerous rivers, but none of much importance.

Climate.— The climate is rigorous. Even in the south the winter lasts from six to seven months, and in the north from eight to nine months. Dense fogs are very frequent; heavy rains take place in autumn, and in May and June the thaws put a stop to nearly all traveling. In the north the sun is absent during December and January; but during the short summer, while the sun is almost constantly above the horizon, the heat is often very great; and near Uleaborg, in about latitude 65°, the corn is sown and reaped within six or seven weeks. Crops in all parts of the duchy are exposed to the double danger of being destroyed by sudden frosts, and by the ravages of a variety of caterpillar called turila by the natives.

Various.— The principal geological formations are granite, which very easily disintegrates, hard limestone, and slate. The soil for the most part is stony and poor. Iron, copper, marble, and sulphur are the chief minerals. Rye, oats, and barley are grown. The most important products are timber, potash, pitch, tar, and resin, which are extensively exported. Next to agriculture, stock breeding and fishing form the leading occupations of the inhabitants. The chief imports are salt, grain, and articles of clothing. In 1902 Finland's imports amounted to $45,000,000 and its exports to $39,000,000, giving a total foreign commerce of $84,000,000.

History.— The Finns were pagans and most aggressive. They frequently attacked the neighboring countries, but especially Sweden. They continued to live under their own independent kings till the 12th century, about the middle of which the country was conquered by Saint Eric, the king of Sweden. When he subdued Finland, sent to them Saint Henry, the bishop of Upsal, to preach Christianity to the people. The province of Wiborg was conquered and annexed to Russia by Peter the Great in 1721; the remainder of the country became part of the Russian dominions (also by conquest) in 1809. Ever since that period the Russian government has endeavored, by conciliating the Finnish party, and promoting objects of national importance, to attach the bulk of the population to its interests; but in this it is said not to have been eminently successful. Abo (the ancient capital), Wasa, and Wiborg are the places where law courts are held. In 1640 a university was established at Abo, but it was removed later to the present capital, Helsingfors. The majority of the people are Lutherans, but many belong to the Greek Church. The emperor of Russia nominates the 18 members who constitute the highest administrative body possessing authority over Finland. The states, composed of the representatives of four social orders, that is, nobles, clergy, burgesses, and peasants, are convoked by the emperor; and no new laws can be enacted, nor new taxes imposed, without their sanction. These four orders form the Diet, which meets every few years for the transaction of business. The governor-general of Finland, who represents the emperor, is president of the senate, usually a Russian, and is appointed by the emperor. The ordinary procedure of the courts of law is in accordance with the forms in existence under Swedish rule.

Language and Literature.— The language of the Finns (Finnish or Chudic) belongs to the northern division of the Ural-Altaic family of languages, and is most nearly allied to the languages of the Esths, Lapps, Mordvins, Voguls, and Hungarians. It possesses all the German vowels, *a, e, i, o, u, ä, ö, ü,* which again give 8 double vowels and 12 diphthongs. Like the other Altaic languages it adheres to the "law of harmonic sequence of vowels," according to which the vowels are divided into two classes, heavy (*a, o, u*) and light (*e, i,* etc.), and only vowels of the same class can occur in the same word. The language is remarkably rich in declensional forms, there being as many as 15 different cases expressing such relations as are expressed in English by *near, to, by, on, in, with, without, along,* etc. By this means these cases are made to express the relations of space, time, cause, etc. There is no distinction of gender in Finnish nouns. The possessive pronoun is indicated by suffixes. The verb resembles the noun in its capability of taking on different shades of meaning by corresponding modifications, and is in this respect a remarkable philological phenomenon. The Finnish proper is divided into three principal dialects, the Karelian or eastern; the Savo in central Finland; and the Tavastian in the west. This latter was used in the original translation of the Bible, and thus became the parent of the literary Finnish.

Finnish literature is valuable chiefly for its rich stores of national poetry, which has been collected only in modern times. Longfellow's 'Hiawatha' is, in style, an imitation of the Finnish epic. The old and popular poetry of the Finns, as it appears in the various *runor* or ballads, is governed by rules of "quantity" as in that of the Greeks and Romans, not by accent; rhyme occurs only rarely; alliteration is employed as a rule. These poems, which had been preserved by oral tradition, were collected by Lönnrot, and in 1835 he published them, under the title of 'Kalevala,' with a second enlarged edition in 1849. He also published in 1840 'Kanteletar,' a collection of 592 ancient lyric poems and 50 old ballads; the 'Suomen kansan sanalaskuja' (1842), a treasury of 7,077 popular proverbs; and 'Suomen kansan arwoituksia' (1844), a collection of 2,188 riddles. Another work that deserves notice is Eero Salmelainen's collection of legends and stories in prose, 'Suomen kansan satuja ja tarinoita' (4 vols. 1854-62). The first book in the Finnish language was printed at Abo in 1544, its author being Michael Agricola, afterward bishop of Abo, who also translated the New Testament and part of the Old into Finnish. A complete Finnish Bible appeared in 1642. Lönnrot's Finnish-Swedish dictionary has been published by the Finnish Literary Society, and Dr. Donner has a dictionary of the Finno-Ugric languages in German. Finnish is becoming more and more the vehicle for imparting instruction. There are many establishments for the higher education of both sexes in which the Finnish tongue is used, and about half of the 800 students at Helsingfors University speak Finnish. Works on science and history, as well as poetry, have been written in Finnish in recent times, and there are now a considerable number of Finnish newspapers. Pop. 2,483,249. Pop. of Helsingfors, the capital, 77,500.

Consult: Topelius, 'Finland Fræmstalldt i Teckning'; Gerschau, 'Versuch einer Gesch. Finland'; Brown, 'Finland in Archaic Times' (1893); Finnish authors, 'Finland in the Nineteenth Century'; Clive-Bayley, 'Vignettes from Finland' (1895); Tweedle, 'Through Finland in Carts' (1903).

Finland, Gulf of, an arm of the Baltic Sea, on the east side, having Finland on the north, and the Russian governments of Esthonia and Saint Petersburg on the south. The length of the gulf from east to west is about 250 or 260 miles; breadth at the entrance or narrowest part, 40 miles; toward the head, where it is widest, about 80 miles. It receives but few rivers, and none of them, with the exception of the Neva, which enters it at its upper extremity, of any great size. It contains numerous islands, of which Kronstadt (q.v.) is the largest. There are various cities and towns of considerable importance along its shores, Saint Petersburg on its eastern extremity.

Fin'lay, Charles John, American physician: b. Puerto Principe, Cuba, 3 Dec. 1833. He studied at the Rouen Lycée, France, and was graduated from the Jefferson Medical College, Philadelphia, in 1855. In 1881 he was delegate from Cuba to the international sanitary conference at Washington, and in 1903 to the sanitary congress also held there. In 1902 he was made chief sanitary officer of Cuba. Finlay was the first to set forth the theory of the transmission of diseases by the agency of mosquitoes, which he advocated in connection with the yellow fever as early as 1881.

Finlay, George, English historian: b. Faversham, Kent, 21 Dec. 1799; d. Athens, Greece, 26 Jan. 1875. Fired with enthusiasm on behalf of Greece he went to that country to help it in shaking off the Turkish yoke, and spent some time at Missolonghi in close intimacy with Lord Byron. He purchased land in Attica, and henceforth lived chiefly in Greece. His great work on Greek history came out at intervals between 1844 and 1861, and shortly after his death it was published as thoroughly revised and greatly improved by himself, entitled 'A History of Greece from its Conquest by the Romans to the Present Time, 146 B.C. to 1864 A.D.' It has been described as the greatest historical work in English since Gibbon's 'Decline and Fall.'

Finley, John Huston, American educator: b. Grand Ridge, Ill., 19 Oct. 1863. He was graduated at Knox College, taking a post graduate course at Johns Hopkins University. He served as secretary of the State Charities Aid Association of New York 1889-92, founding and editing the 'State Charities Record' and 'The Charities Review.' He was president of Knox College 1892-9, editor of 'Harper's Weekly' for 1899, and editor of 'McClure's Magazine' 1900. He was appointed professor of politics at Princeton 1900, and became president of the College of the City of New York in 1903. He collaborated with R. T. Ely (q.v.) in writing 'Taxation in American States and Cities.'

Finley, John Park, American meteorologist: b. Ann Arbor, Mich., 11 April 1854. He was educated at the State Normal School and State Agricultural School. In his position as chief of the Signal Service Bureau of the Pacific Coast he has given much attention to the phenomena of meteorology, and has written extensively upon the subject. His works include: 'Tornadoes' (1887); 'Manual of Instruction in Optical Telegraphy' (1889).

Finley, Martha (pseudonym of MARTHA FARQUHARSON), American writer for girls: b. Chillicothe, Ohio, 26 April 1828. She has published: 'Elsie Dinsmore' (1868); 'Wanted — A Pedigree' (1872); 'The Thorn in the Nest' (1886); 'Twiddledetwit' (1898); etc. She is best known by her 'Elsie Books,' over 25 in number, and 'The Mildred Books.'

Finley, Samuel, American Presbyterian clergyman: b. Armagh, Ireland, 1715; d. Philadelphia 17 July 1766. Arriving in America in 1734, he was licensed to preach in 1740. The first part of his ministry was much occupied with itinerant labors in promoting the revival of religion, at that time so remarkable throughout the country. His zeal at one time brought him into unpleasant circumstances; for preaching in New Haven, Conn., contrary to a law of the colony forbidding itinerants to enter parishes of settled ministers without their consent, he was seized by the civil authority and carried as a vagrant beyond its limits. In 1744 he was settled at Nottingham, Md., where he remained for seven years, and where, in addition to his ministerial duties, he carried on an academy which acquired a high reputation. In 1761 he became president of the College of New Jersey, now Princeton University.

Fin'ney, Charles Grandison, American Congregational minister: b. Warren, Conn., 29 Aug. 1792; d. Oberlin, Ohio, 16 Aug. 1875. He went to Oneida County, N. Y., in early life and was ordained minister 1824, becoming professor of theology at Oberlin College in 1835 and its president in 1852. He was one of the most famous of American revivalist preachers. Among his works are: 'Lectures on Revivals' (1835; new edition 1868); 'Lectures to Professing Christians' (1836); 'Sermons on Important Subjects' (1839); 'Lectures on Systematic Theology' (1847); 'Autobiography,' and 'Sermons on Gospel Themes' (1876).

Finns, in their own language called *Suomalainen,* and by the Russians *Chudes,* are in the narrower sense a race of people inhabiting the northwest of European Russia (governments of Archangel and Olonetz), but especially the Grand-duchy of Finland. In a wider sense Finnic is the name applied to one of the five chief branches of the northern or Ural-Altaic family of peoples and languages. These peoples were formerly spread over the whole north of Asia and north of Europe, and they are divided into the five families, the Tungusic, Turkic, Mongolic, Samoiedic, and Uralo-Finnic or Finnic family proper. The last or most westerly family still forms the population of north Europe and northwest Asia, and formerly covered the greater part of Scandinavia. It is again divided into four groups or branches (1) the Ugric, to which the Ostiaks, Voguls, and Magyars belong; (2) the Bulgaric or Volgaic, consisting of the Tcheremisses and the Mordvins; (3) the Permic, composed of the Permians, Sirianes, and Votiaks; and (4) the Chudic or Baltic group. To the last belong, besides the Finns proper, the Esths of Esthonia and the Lives or Livonians, the Chudes (in the narrower sense), that is, Karelians, Vepses, and Votes, in the governments of Novgorod and Olonetz, and the Lapps in Archangel and the northern parts of Finland, Sweden, and Norway. The Finns proper are divided into two branches: the Tavastians in the southwest, and the Karelians in the east of Finland. The Finns may properly be identified with the Scythians, and their earliest seats appear to have been the Ural Mountains and the neighborhood of the Caspian Sea. They originally led a peaceful nomadic life, but subsequently practised agriculture and adopted settled habits. They seem to have been compelled to migrate more to the northwest about the beginning of the Christian era, by the pressure of the Gothic tribes, and the country west of the Ural Mountains, more particularly the region where the Great and Little Volga unite, became their second home. From this the bulk of them had again to remove to their present abodes, though considerable numbers were left on the Volga, Oka, Kama, about the sources of the Dwina, in the Ural, and others again spread eastward, some of them as far as the Altai Mountains. The Finns are a serious people, and their so-called amusements show this trait. They are educated, and have most decided opinions as to «Woman's rights»; coeducation is the rule. Although Finland has been united with Russia, or a part of Russia, since 1809, yet the better educated Finns speak the Swedish language. The emperor encourages the use of the Finnish language. The Finns are communicative on business matters and often do not hesitate to tell what other people might call «family secrets.» They ask freely about the affairs of others. They have choirs and musical societies in Finland, and where found in other countries they show a love for music, although their music lacks all suggestion of joyousness. See FINLAND.

Finot'ti, Joseph Maria, American Roman Catholic clergyman and author: b. Ferrara, Italy, 1817; d. Denver, Col., 1879. He studied theology in the Jesuit College, Rome, and in 1845 removed to the United States. In 1852 he left the Jesuit Society and became literary editor of the Boston 'Pilot.' His works include: 'A Month of Mary' (1853); 'Italy in the 15th Century,' 'The French Zouave' (1863); 'American Catholic Bibliography' (unfinished).

Finsen, Neils R., Danish physician, scientist and discoverer of the method of curing lupus or tuberculosis of the skin, and other skin diseases, with light rays: b. Iceland in 1860; d. Copenhagen, Denmark, 24 Sept. 1904. Prof. Finsen's great discovery, that sunlight and electric light rays contain properties that can be used to cure skin diseases and blemishes, was the outgrowth of his experiments begun as a student in the Copenhagen University. In a small attic room of the old surgical academy building the investigation started. A fellow student, Sophus Bang, shared Finsen's enthusiasm for a complete reform in therapeutics. When ill-health came to both young students, Bang sought refuge from his disease in Switzerland, and since has become one of the foremost anatomists of Europe. Finsen remained at home to carry on his investigation in the foggy and cold climate of Copenhagen.

In 1890 Prof. Finsen was graduated from the Copenhagen University, receiving his doctor's degree. Three years later he published in a medical journal an article on 'The Influence of Light on the Skin,' which aroused general attention because of his assertion that cases of smallpox could be cured by putting red curtains at the windows of the sick-room. This was the beginning of the final triumph. Smallpox became epidemic in 1894 in Copenhagen and the new method was put to the test. The red-room treatment became popular with both the medical profession and the public, for by it not only was the disease cured, but the red rays prevented suppuration and left the patient unmarked by the dreaded scars.

The red-light treatment was but one application of Prof. Finsen's theory that light rays contained healing, and at the best it was but a negative result; it cured only when the disease had run its course. To develop the positive element of the light-ray cure, Prof. Finsen began experimenting with artificial light rays. Soon he found it possible to concentrate rays of the ordinary electric light in such a way as to cure a lupus patient who for eight years had tried every known method. The cure attracted great attention, and both moral and financial support came to the young investigator and discoverer. In 1896 the municipal hospital of Copenhagen gave room on its ground for several small buildings, in which Prof. Finsen's experiments continued on an increasing scale. Then the Danish government came to the support of the institution and it was enlarged and removed to Rosenvaenget, a pleasant suburb of Copenhagen. Many cures of cases previously deemed hopeless were made through the new and enlarged apparatus, the high-power Finsen lamp, which was used under the direction of a staff of physicians of national renown, expert electricians, and specially trained nurses, headed by Prof. Finsen.

Prof. Finsen claimed his invention was prior to that of Prof. Roentgen by about a year. To Finsen is due also the discovery that certain rays of the sun's spectrum are bacteria-destroying, while others are of a healing and curative nature. In December 1903 Prof. Finsen received the Nobel medical prize from the Norwegian parliament. Institutions for the use of the rays are now established in every civilized country.

Few scientists have been recognized as has Prof. Finsen. In April 1904, when King Edward and Queen Alexandra were in Copenhagen, they personally called on Prof. Finsen, and at his bedside expressed their sorrow at his illness. They also congratulated him on his wonderful success.

At his funeral two kings were present, King Christian of Denmark and King George of Greece, and almost every European ruler was personally represented, while princes and high ministers of state and leading scientists paid a last tribute to the dead man.

Wreaths carried by special representatives came from Emperor William, King Edward, Queen Alexandra, and Count Von Bulow, the German imperial chancellor, and the Crown Prince of Denmark; Princes Waldemar, Karl, and Hans were present at the church. See Finsen Light; Phototherapy.

Finsen Light, Finsen ray, blue light, actinic ray, violet and ultra-violet ray, light cure. The Finsen Light takes its name from its discoverer, Prof. Niels R. Finsen. There is a distinction between the "Light Cure" and the Finsen Light Treatment. Sunlight possesses therapeutic properties, and its beneficial effects on animal and vegetable life have been known from time immemorial. But simple exposure to ordinary sunlight will not cure any of the diseases amenable to the Finsen Light Treatment. Prof. Finsen discovered that the actinic rays, those represented in the blue, indigo, violet and ultra-violet sections of the solar spectrum, possess strong bactericidal power, and when concentrated and applied, they will destroy bacteria in five or six minutes.

While the bactericidal features of the violet rays were known experimentally in 1877, lacking the scientific basis, believing the discovery to be a cure-all, "the blue light" was laughed at as quackery. It remained for Prof. Finsen to make a practical application of the facts in treating certain diseases previously supposed to be incurable.

The Finsen Light is a large, specially constructed arc lamp of 40,000 candle power, or forty times stronger than an ordinary arc street lamp, and uses from 60 to 80 amperes of current of 110 voltage. This lamp burns a specially made carbon. In the upper holder is a large carbon, while a smaller one is used in the bottom holder. When properly adjusted for arcing, a maximum number of violet and ultra-violet rays are produced.

The light from this lamp is so intense it is impossible to look at it with the naked eye, and it is necessary for all the attendants and patients to wear smoked glasses while the lamp is in operation. An aluminum hood about two feet wide surrounds the lamp, which hood is fringed on its lower border with a deep crimson-colored paper skirt to further aid in excluding the diffused light from the patient. The concentrated rays are carried from the arc to the patients through four telescopic tubes, known as converging tubes, suspended at an angle of 45°. Each tube contains a series of rock crystal lenses, which are very expensive, but are used because they absorb a greater amount of heat rays, but do not interfere with the passing of chemical rays. These rock crystal lenses are so arranged that reservoirs for running water exist between them. By means of these water screens and the rock crystal lenses, all rays but the violet are eliminated. These rays are converged, concentrated and filtered, thus vastly increasing the healing and bactericidal effects. The heat from the original arc is so intense, that to prevent cracking of the lenses, a stream of cold water is kept constantly circulating through the upper reservoirs or water screens.

To further concentrate and cool the rays a compressor is provided which consists of two rock crystal lenses so arranged in a brass band that a chamber for running water exists between them. This part of the apparatus is used to compress the affected area and make it bloodless during treatment, which facilitates deeper penetration, as the red blood corpuscles have a tendency to obstruct or absorb the actinic rays.

Its advantage over other lamps is due to the greater number of violet or chemical rays produced; its advantage over sunlight is because the atmosphere absorbs a large percentage of the sun's chemical rays. The treatments are given while patients recline on couches, which offer every facility for comfort and quick rearrangement of position. The affected area is placed about 10 inches from the distal end of the converging apparatus, and the treatments, or seances as they are called, take about one hour daily in lupus and rodent ulcer, and in other skin diseases from 10 to 20 minutes, depending upon each individual case. The treatment causes no pain; a red erythematous spot, or blister, appears some hours after the treatment has been given. In a few hours these blisters dry up and a scab forms; in five or six days the scab falls off and the ulcer is healed beneath, leaving the skin free from scar or cicatrix, but red. The redness, however, after a short period fades and leaves the skin white and uncontracted, except where there has been a loss of tissue from the disease before treatment.

The Finsen high power apparatus has maintained its supremacy unrivaled in the treatment of deep-seated affections. None of the cheaper apparatus, such as the London Hospital Lamp, the Dermo Lamp, and the apparatus of Lortet and Genou, Bang, Foveau and Trouvet, Broca-Chatin, or any of the imitation lamps now made in America, have succeeded in producing the therapeutic actinic rays of sufficient strength to cure deep-seated diseases of bactericidal origin, and only in the institutes equipped with Finsen's High Power Apparatus has any positive success been achieved in the treatment of these dread diseases.

The Finsen light treatment has an advantage over the X-ray, in that there is absolutely no danger of burning and consequent sloughing. In the thousands of cases treated by the Finsen light there is not one case recorded that has suffered any ill effects. Such cannot be said of the X-ray treatment, for hundreds have been severely and permanently injured by use of this treatment. The reason for this is, in using the Finsen light treatment we are dealing with a known quantity, while with the X-ray we have an unknown quantity of uncertain action.

On 10 Dec. 1903 the Norwegian Parliament awarded the annual Nobel prize of $40,000 to Professor Finsen, for making the most notable discovery in medical science during the year. To-day, no name in the scientific catalogue is better known than that of Professor Niels R. Finsen, of Copenhagen, Denmark. Since the discoveries of Pasteur, the Roentgen rays are, perhaps, the most wonderful addenda to the history of medicine. But while the latter may be termed the search-lights of the modern surgeon and his class, Professor Finsen stands absolutely alone in the particular field he has selected. Professor Finsen claims that his discovery has priority over the X-ray by about one year. While it has been demonstrated that the Finsen light treatment is a positive cure for lupus (skin consumption), it is now known by recent experiments that it has a much greater range of usefulness than was originally claimed for it. It is now used with decided success in cases of epithelioma (skin cancer), acne vulgaris, acne rosacea, psoriasis, eczema, alopecia-areata (baldness), chronic ulcers, naevus (birth-mark), and tubercular affections involving bone.

If physicians the world over would do nothing more than apply the Finsen light in the removal of birth-mark, such as port wine stains, the discovery would have justified itself by its results. It has been found that the actinic rays can penetrate the human thorax, and this being the case, there is no reason to doubt the conclusion that the Finsen light treatment will later be recognized as a valuable aid in the eradication of the great white plague.

After the cure of Niels Morgenson, of a disease pronounced incurable, Finsen had done what doctors and surgeons would have laughed at as a mad impossibility; he had cured a case of lupus with electric light, using an ordinary hand lens to concentrate the actinic rays. In the fall of 1895, success followed success until the Danish government recognized the value of Finsen's discovery and subsidized the Finsen Medical Institute at Copenhagen. During a period of nine years this institute has grown from a small shed, where they were only able to treat one patient at a time, to a magnificent institute where they are now treating 400 patients daily. Other European nations sent special representatives to Copenhagen to investigate this new "light cure," and the result was that institutes were established, one in London by the queen of England, another in Saint Petersburg, Russia, by the princess of Russia, and others in Manchester, England; Paris, France, and Chicago, Ill. These various institutes are carrying on a work similar to that of the parent institute at Copenhagen.

The great cost of installing and maintaining Finsen's high power apparatus has prevented many communities from receiving the benefits of this treatment. It is to be hoped that science may yet find a more simple and less expensive method of producing and applying the chemical rays in such quantity and of such therapeutic power that Professor Finsen's discovery may be denied to none. Statistics which have been compiled by the different institutions using the Finson high power apparatus are as follows: At Copenhagen, of 1,367 cases treated up to May 1904, 86 per cent were cured, over 1,000 of which were lupus vulgaris; at the London hospital, 78 per cent of all cases were cured, 10 per cent improved, and 12 per cent disappeared from observation. The Manchester hospital report 92 per cent of cured or improved, 8 per cent disappeared from observation. The Finsen Light Institute of America, located at Chicago, Ill., up to 1 Aug. 1904, reports on 493 cases treated: 82 per cent cured, 9 per cent decidedly improved, 9 per cent failures. In the United States consular reports on file in Washington, D. C., under date of 5 Feb. 1904, will be found the official report of the Hon. R. R. Frazier, United States consul at Copenhagen, regarding the work of the parent Finsen Light Institute.

Prof. Finsen goes so far as to say that in Lupus Vulgaris cures can be obtained in 97 per cent of all cases even where the entire face is involved. In conclusion the author would state, that as a result of the investigations and experiments now being made, we may hope for and reasonably expect that the near future will clear up many a doubtful point and show greater possibilities of the light treatment in the curing of disease. There is no doubt that the Finsen light treatment has taken an exalted position in the field of surgery and advanced therapeutics.

Vice-Pres. Finsen Light Institute of America.

Fionni, Matteo, māt-tā'ō fē-ōn'nē, Italian geographer: b. Felizano, Piedmont, August 1827; d. Bologna 1901. He was instructor in the University of Turin 1848–60, then becoming professor of geodesy at the University of Bologna. Among his works are: 'Le Allusione' (1878); 'Le Proiezioni della carte geografiche' with atlas (1878); 'Note ipsometrische sopra la regione bolognese' (1883); 'Mesure offerte delle carte geografiche' (1887); 'Le Projezione cuneiformi' (1889).

Fiord, or **Fjord,** the Norwegian name for a long and comparatively narrow bay or inlet. In North America on the coast of Maine and the coasts of British Columbia and of southern Alaska are bays of this type. Fjords are found on coasts where the land, having been deeply carved either by streams of water or glaciers, is now slowly sinking. In the Norwegian and Alaskan fjords much if not the greater part of the erosion was by ice.

Fir, a name sometimes used as co-extensive with the term pine, and including the whole genus *Pinus*. In a narrower and stricter sense it is the name of a genus of trees (*Abies*) belonging to the order *Coniferæ,* and the sub-order *Abietineæ,* having solitary leaves growing round the branches. The fir is thus distinguished from the pine, the leaves of which grow in twos, threes, fours, or fives; and from the cedar and the larch, both of which have the leaves fasciculated. The term fir, thus limited, is applied only to the different varieties of the silver fir and the spruce fir. The silver firs are distinguished by having the cones erect, scales deciduous, and leaves flat. The common silver fir is the *Abies picea* of botanists, the *Pinus picea* of Linnæus. It is a native of the middle and south of Europe. The finest trees of this species are found in southern Italy; but the largest forests are those on the slopes of the Pyrenees, especially on the French side. It always prefers mountainous regions, and is sometimes found at a height of nearly 6,000 feet. The height of the trunk is sometimes 150 feet, and the diameter above 6 feet. It is the *sapin* of the French, and the *abies* of the ancient Romans. It is from this tree that Strasburg turpentine is procured; and its wood is of great use in ship-building (for masts, yards, and spars), in house-carpentry, etc. To this genus also belong the *A. sibirica,* found on the Altaian Mountains; the Indian silver fir, a native of the slopes of the Himalaya Mountains; and the *A. canadensis* or hemlock spruce fir. Other species of *Abies,* found in western North America (as also in the Himalayas), are trees sometimes rivaling in size the Douglas fir (mentioned below), and likewise yielding excellent timber. Among them are *A. grandis,* a Californian tree of 170 to 200 feet in height; *A. amabilis,* a species much resembling it; *A. nobilis,* a majestic tree, which forms vast forests on the mountains of northern California; *A. bracteata,* a Californian species remarkable for its slender stem, which rises to a height of 120 feet, and yet is only about one foot in diameter at the base, and likewise for the manner in which the middle lobe of each bractea of its cones is produced so as to resemble a leaf. Very similar to the silver fir, but generally of much smaller size, and indeed seldom much above 30 feet high, is the balm of Gilead fir (*A. balsamea*), a native of North America from Virginia to Canada. The wood is of little value, but the tree yields Canada balsam (q.v.).

The spruce firs have the cones pendulous, scales persistent, and leaves tetragonous. Of this division the common or Norway spruce fir (*A. excelsa*) is the most important. It gets the name of the Norway spruce from the fact that in that country it constitutes the principal timber; but it is also extensively cultivated in the middle of Europe, and is found all over Siberia to lat. 70° N. The average height of the tree is from 80 to 150 feet; and it attains its maturity in about 70 or 80 years. The branches, regularly arranged round the main stem and gradually diminishing toward the top, give the tree a pyramidal form. Nearly every part of this tree is of use. The wood (white or Christiania deal) is adapted to various ordinary purposes; the longest and thinnest stems are very valuable in ship-building for making masts; and the stems of those trees that are found at a great height, and in which accordingly the yearly rings are very narrow, are eagerly sought by musical instrument makers for sounding-boards. The bark is used in tanning; the young buds or shoots are used in making the drink known as spruce beer; and the resin which exudes from the tree supplies the common frankincense, and the Burgundy pitch of commerce. The so-called Scotch fir is really a pine (q.v.).

The *Pseudotsuga douglasii,* closely related to the firs, and often regarded as a fir, is named after the Scotch botanist David Douglas, who visited the Pacific coast during the first half of the 19th century, and is known as the Douglas fir or spruce, red fir, yellow fir, Oregon pine (q.v.), etc. It is one of the most important trees of western America, especially of the Pacific States and British Columbia. It is a noble tree, often attaining a height of more than 250 feet, and forms immense forests, especially from lat. 43° to lat. 52°. The bark, when the tree is old, is rugged, and is from six to nine inches thick. The tree abounds in a clear, yellow resin. The timber is heavy, firm, and valuable, and the growth of the tree is very rapid.

Fir'bolgs, or **Fir-Bolgs** (fir-man; bolg'-bag; bag-men), a name given to the descendants of one of the colonies of Nemedians, who fled from Ireland to Greece in about 1900 B.C. Nemedia, or Neimheidh, and his wife Macha, his 4 sons, 34 ships with 30 persons in each ship went from Greece to Ireland because some of the lineage of Nemedia had some years before gone from Greece to Ireland. They found in possession of the country Africans called Fomorians or Fomharaighs, and sometimes pirates. After several conflicts between the Nemedians and Fomorians, the Nemedians were reduced to slavery or flight; they chose the latter. Simon Breac led a colony to Greece, where they were also persecuted and made to serve the people whom they found in the country. One of their tasks was to dig "in the low deep soil," and carry the earth in leathern bags to cover and improve the barren places. From this labor came the name Fir-Bolgs or bag-men. After some years of bondage they again took flight to Ireland, no less in number than 5,000 men and women, under five leaders. See IRELAND.

Firdausī, fēr-dow'-sē, Persian poet: **b.** Schadab, near Tūs, in Khorassan, about 935; d. there 1020. With the name of Firdausī in the 10th century of our era, modern Persian poetry may be said to begin. Firdausī, however, really forms only one link in the long chain of Iranian literature which extends over more than 25 centuries, and whose beginnings are to be sought in the Avesta, 500 years before the birth of Christ.

The Mohammedan conquest of Iran by the Arabs somewhat resembles, in its effect upon Persian literature, the Norman conquest of England. Hardly two centuries had elapsed before an Iranian renaissance is begun to be felt in Persia. Firdausī comes 300 years after the battle of Nihāvand, in which the eagle of the Persian military standard sank before the crescent of Allah's prophet and the Mohammedan sword; just as Chaucer followed the battle of Hastings by 300 years.

Such was the literary situation at the end of the 9th century. Firdausī was the poet in whom the wave of the national epos culminated in the 10th century. But as there were English poets who struck the note before Chaucer, so in Persia, Firdausī had his literary predecessors. Abbas of Merv (809) was one of these earlier bards. Of greater repute was Rūdagī (died 954) who is said to have composed no less than a million verses. But Firdausī's direct predecessor and inspirer in the epic strain was Daqīqī, cruelly murdered when he had sung but a thousand lines. Yet these thousand verses are immortal, as Firdausī has incorporated them into his poem and has thus happily preserved them. They are the lines that describe the founding of the religion of Zoroaster, priest of fire. There was possibly a certain amount of tact on Firdausī's part in using these, or in claiming to employ Daqīqī's rhymes: he thus escaped having personally to deal with the delicate religious question of the Persian faith in the midst of the fanatical Mohammedans, who are said to have assassinated Daqīqī on account of his too zealous devotion to the old-time creed. With Firdausī, then, the new Persian era is auspiciously inaugurated in the 10th century; its further development through the romantic, philosophic, mystic, didactic, and lyric movements must be sought under the names of Nizāmī, Omar Khayyām, Jalāl-ad-dīn Rūmī, Sa'dī, Hāfiz, and Jāmī.

Firdausī is pre-eminently the heroic poet of Persia. His full name seems to have been Abulqasīm Hasan (Ahmad or Mansur); the appellative "Firdausī" (Paradise), by which he is known to fame, was bestowed upon him, according to some accounts, by his royal patron the Sultan Mahmūd. Firdausī's native place was Tūs in Khorassan. By descent he was heir to that Persian pride and love of country which the Arab conquest could not crush. By birth, therefore, this singer possessed more than ordinary qualifications for chanting in rhythmical measures the annals of ancient Iran. He had undoubtedly likewise made long and careful preparation for his task, equipping himself by research into the Pahlavī or Middle Persian sources, from which he drew material for his chronicle-poem. From statements in the 'Shāh Nāmah' itself, we may infer that Firdausī was nearly 40 years of age when he made the real beginning of his monumental work. We likewise know, from personal references in the poem, that he had been married and had two children. The death of his beloved son is mourned in touching strains. One of the crowning events now in the poet's life was his entrance into the literary circle of the court of Sultan Mahmūd of Ghazna, who ruled 998–1030. To Mahmūd the great epic is finally dedicated, and the story of Firdausī's career may best be told in connection with the masterpiece.

The removal of the heroic bard Daqīqī by fate and by the assassin's dagger had left open the way for an ambitious epic poet. Firdausī was destined to be the fortunate aspirant. This poet laureate lived long in the sunshine of the court, and was promised a gold piece for each line he composed. The liberality of Sultan Mahmūd's favor called forth from Firdausī a splendid poetical panegyric, that is only eclipsed by the fierce savageness of the scathing satire which later the poet poured out against his royal patron, when disappointed in old age of the promised reward that was to crown his great work.

Tradition narrates that Firdausī was a septuagenarian when he finished the last line of the 60,000 rhyming couplets that make up the 'Shāh Nāmah.' He now looked for the reward of his life's work. But jealousy and intrigue against him had not been idle during his long residence at court. The grand vizier appears to have induced the sultan to send Firdausī 60,000 silver dirhems, instead of the promised gold. Firdausī is said to have been in the bath when the elephant laden with the money-bags arrived. On discovering the deception, the injured poet rejected the gift with scorn, and dividing the silver into three portions, he presented one of these to the bath steward, the second to the elephant-driver, and he gave the last to the man who brought him a glass of cordial. He then wrote the famous satire upon Mahmūd, and fled from the city for his life. For 10 years the aged singer was an exile, and he would have been a wanderer but for the friendly protection extended to him by a prince of Irāq, who apparently also tried, without effect, to reconcile the sultan and the aged poet. Enjoying the solace of this prince's shelter, Firdausī composed his last work, the 'Yusuf and Zulīkha,' a romantic poem nearly as long as the Iliad, on Joseph and the passionate love of Potiphar's wife for him.

But Firdausī was now advanced to his 80th year, and he seems to have longed to visit his native town of Tūs once more. A sad story is preserved of his death of a broken heart. It is also told that Mahmūd relented and sent to the city of Tūs a magnificent caravan conveying gifts and robes for the aged singer, and bearing likewise the 60,000 gold pieces that had once been promised. But all too late. The treasure-laden camel procession met at the city gate the funeral cortège that was conducting the dead poet's body to the grave. Firdausī's death occurred in 1020. His tomb at Tūs is still a place of pious pilgrimage.

The story of the 'Shāh Nāmah,' — Book of Kings,— may be described in briefest words as the chronicle-history of the empire of Iran, from the moment of its rise in legendary antiquity and during the golden reign of King Jamshīd, through its glorious ascendency under the majesty of the Kayanian rulers, and down to the days of Zoroaster; thence onward to the invasion of Persia by Alexander the Great. The poem from this point follows the various fortunes and changes of the Persian sovereignty, until its downfall and ruin before the Mohammedans and Islam. Firdausī naturally treats his subject as a poetic chronicler, not as a historian;

but there is history in the poem, and he has given a certain unity to his long epic by keeping sight of the aim that he had in view, which was to exalt the fallen glory of Iran. The epic is written in a style befitting the theme. A word must also be bestowed upon Firdausī's romantic poem 'Yusuf and Zulīkha,' in which the biblical story of Joseph, as narrated in the Koran, was his source. This poem was in great measure the work of his old age, as it was written after he was 70; but in the episode of Joseph and Potiphar's wife the luxuriousness of color, the richness of imagery, the lavish exuberance, and the passion, might in some degree allow of comparison with Shakespeare's 'Venus and Adonis,' or with Marlowe's 'Hero and Leander.'

Translations of Firdausī should be mentioned. There is an English abridgment of the 'Shāh Nāmah' with versions in prose and in rhyme by James Atkinson — 'Shāh Nāmah' (1832; cheaply reprinted in the 'Chandos Series,' New York 1886). Several versified selections are found in Robinson, 'Persian Poetry for English Readers' (privately printed; Glasgow 1883). There is a standard French prose translation of the entire 'Shāh Nāmah' by Jules Mohl, 'Le Livre des Rois' (7 vols. Paris 1876–8). An Italian prose rendering, also complete, has been made by Italo Pizzi, 'Firdusi, Il Libro dei Re' (8 vols. Turin 1886–9); and Pizzi has given extensive metrical renderings in his 'Storia della Poesia Persiana' (Turin 1894). In German there is a running paraphrase of the story by Görres, 'Heldenbuch von Iran' (2 vols. Berlin 1820). Spirited renderings of selections have also appeared in German; by A. F. von Schack, 'Heldensagen des Firdusi' (3 vols. Stuttgart 1877); and by Rückert (unfinished), 'Firdosi's Königsbuch Schahname' (ed. Bayer, 3 vols. Berlin 1890–5). Of the 'Yusuf and Zulīkha' (complete) there is a German translation into rhymed verse by O. Schlechta-Wssehrd, 'Jussuf und Suleicha' (Vienna 1889).

A. V. Williams Jackson.

Fire, the agent of purification; one of the so-called four elements which burns, inflames, warms, or heats; the igneous principle; heat and light emanating visibly, perceptibly, and simultaneously from any body; caloric; the effect of combustion. The terrific energy of fire, the most important agent of civilization, the similarity of its effects with that of the sun, its intimate connection with light, its terrible and yet genial power, and the beauty of its changeful flame, easily account for the reverence in which it was held in ancient times. At a period when cause and effect, form and essence, were not distinctly separated, fire became an object of religious veneration, a distinguished element in mythology, an expressive symbol in poetry, and an important agent in the systems of cosmogony. It gained a place among the elements, and for a long time was believed to be a constituent part in the composition of all bodies. At a later period, fire, under the name of phlogiston, was considered to be the source of all chemical action. See Combustion; Heat.

Fire-alarm, an apparatus, mechanical, electric, and telegraphic, used for detecting fires, and for giving instantaneous notice of an outbreak. See Electric Signaling.

Fire Annihilator, or **Extinguisher,** an apparatus for extinguishing fire. It is charged with water and a mixture of dried ferrocyanide of potassium, sugar, and chlorate of potassa. It is set in action by a blow on a glass bottle containing sulphuric acid, which flows over the charge and liberates gas, which, with the water, is emitted at a nozzle and expended upon a fire to quench it. The earliest of modern fire-extinguishers seems to have been that invented by W. A. Graham, of Virginia, about 1837. It consisted essentially of a contrivance by means of which carbonic acid gas dissolved in water under pressure could be liberated and directed upon burning objects. Many subsequent improvements have made Graham's fire-extinguisher more useful. The Babcock extinguisher consists of a vessel filled with a solution of bicarbonate of soda. In the upper part of the vessel there is a smaller one containing sulphuric acid, suspended by pivots below its centre. When not in use the inner vessel is kept upright by a rod passing through the stopper of the larger vessel, but in case of fire the rod is withdrawn, thus permitting the inner vessel to topple over and mingle its contents with the bicarbonate of soda. The result, of course, is that carbonic acid gas is at once liberated. Many automatic fire-extinguishers, intended to be brought into operation by the rise of temperature caused by fire, have been used with more or less satisfactory results.

Fire Armor, a device to protect firemen and others from the effects of smoke, gas, etc. The first patent for a device of this kind given in the United States was granted to W. H. James in 1828. In this, air was supplied from the receiver worn round the waist, to a mask which enclosed the wearer's face, care being taken to prevent too great pressure from the air. Another one called the "eye and lung protector" was first used in 1873, and was adapted to protect the eyes from the effect of dust, smoke, etc., with plates of transparent mica for vision. To protect the lungs, a certain kind of porous cloth covered the lower part of the face, which held a wet sponge against the mouth and nostrils. This was used with very satisfactory results. In 1888 a method of supplying a fireman with fresh air was devised by forcing air to the fireman's mask through a pipe carried along the hose. Improvements on this plan have since been made.

Firearms, a general term for all sorts of cannon, guns, rifles, fowling-pieces, pistols, etc., which effect their discharge by the combustion of gunpowder or other explosive. They originated in the East, from which they passed to Europe, cannon being the first firearms to be generally employed. The rifle, originally invented in Leipsic in 1498, was first brought into general military use in America during the Revolutionary War. The riflemen in Kentucky, Tennessee, and the other wildernesses of the United States had long been accustomed to the use of this firearm, and so far as they could be procured, rifles were the arms of the American soldiers in that struggle. In 1813 G. H. Hall suggested that the rifle be loaded at the breech, so that the ball and powder, united in one cartridge, might be inserted without delay, and the piece loaded and fired as rapidly as the muzzle-loading smooth-bore. Hall's idea did not attract much attention in the United States. The army, for the most part, was supplied with flint-locks, and it would have involved considerable expense to change them all over. He also proposed to manufacture the locks and other pieces of the guns by machinery, so as to make the parts of the different guns interchangeable. He was employed at the government armory at Harper's Ferry to introduce the latter idea and experiment with the former. In this he was successful, and the interchangeable system was soon introduced into all the armories of the United States. In 1827 100 of Hall's guns which had been sent to Springfield in 1824 were brought back to Harper's Ferry and placed with 100 guns of current make. The 200 were taken apart, the pieces thoroughly mingled, and the guns then remounted from pieces picked up at random. The whole 200 fitted perfectly. They attracted much attention abroad, and England afterward obtained machinery in the United States, so that she might introduce the system in her factory at Enfield. Prior to 1853 every gun made in England was manufactured by hand. The percussion-cap was proposed by Shaw, of Bordentown, in 1817, and was really an indispensable part of any improved system of firearms.

The principal weapon of a new type brought out a little before the Mexican war was a purely American invention, namely, the repeater. Samuel Colt, a seaman, while on a voyage to Calcutta, devised a six-barreled revolver to be used with percussion-cps. In 1835 he improved upon this and perfected a six-barrel rotating breech. Prior to this there were two common types of pistol: one the small pistol, suitable for use on a small object at 30 yards; and the other the large horse-pistol, which was almost equal to a gun. Patents were issued to Colt for his revolver, and the manufacture commenced in 1835. He turned out 60,000 weapons a year. The large sales brought many competitors into the field, including the manufacturers of the Allen, Derringer, Volcano, Pettinger, Whitney, Smith & Wesson, and Lowell. The pistol was very much employed during the war, and many are even yet sold. Hall's idea of a breech-loading rifle was never put into general use, but in 1852, Stark, of Philadelphia, invented a breech-loading rifle that met with great success. The first of a new class of rifles to come into notice was the Spencer, the chief idea of which was applied to other American guns. This was a repeating rifle, but was almost too heavy to be successful. It was too great a burden for the men to bear in addition to their other accoutrements. The Remington, which has acquired great success, is produced at a factory at Ilion, N. Y., founded in 1825 by Eliphalet Remington. One great cause of the growth of the industry was the War of the Rebellion. The capital invested in 1840 did not exceed $200,000; in 1870 it was over $3,000,000, while at the present time it is about $10,000,000. The annual output of rifles is 1,000,000, and the same number each of shotguns and revolvers. The United States takes precedence in the manufacture of sporting rifles, metallic ammunition, and revolvers. Firearms include:

Pistol.— A small firearm having a curved stock or butt to fit the hand. Of this type there are many varieties, such as single- and double-barreled and revolver. They came into use early in the 16th century. The revolver consists of a tube, or barrel, and a revolving chamber which carries the loaded cartridges, together with the firing mechanism and handle. After firing, the loaded chamber is automatically revolved, by the action of cocking the piece, thus bringing the loaded cartridges successively opposite the barrel and firing mechanism.

Rifle.— A weapon fired from the shoulder, the stock being so formed as to rest against the shoulder when brought into aiming and firing position. The musket used to be so fired; in modern times it has been superseded by the rifle. The modern magazine gun has a much smaller bore than the old musket, and is also shorter in the barrel, yet its carrying power is much greater. This is owing to the improvements made in explosives in recent years, as well as to the rifling, or grooving of the barrel. The rifling consists of a number of spiral grooves cut inside of the gun barrel, the twist or spiral increasing toward the muzzle of the piece. This imparts to the ball a rapid spinning or rotary motion, which prevents its turning over and over endwise, and not only increases the accuracy with which it will follow the aim, but at the same time presents less surface for atmospheric resistance. The term rifle is applied to any musket or gun barrel which is grooved so that the projectile may have a rotary motion on its own axis. The rifling may be polygroove, as in the Armstrong and other guns; with only two grooves, as in some of the early weapons; with the two grooves with the angles rounded away so as to produce an

oval and yet twisted bore, as in the Lancaster guns; or with three or more grooves, as in the most modern weapons. The grooves are of varying size, form, width, and of different degrees of twist in the length of the barrel itself, that of the Henry rifling being one turn in 22 calibres or widths of the bore. The bullet is made to fit the bore either by expansion of the base of the lead bullet, or, as in the early pattern, by having the ball "belted," so that the belt should take the groove and so emerge from the muzzle with a rotary motion.

Carbine.—A short firearm used by cavalry, similar in bore and mechanism to, and carrying the same ammunition as, the infantry rifle.

The preceding table gives data relative to the rifles used by the principal nations.

It will be noticed that the American gun, the Remington, has been adopted only by one foreign power, and that nation the rather small one of Sweden. See ARMS AND ARMOR; ARTILLERY; ORDNANCE; GUN; MUSKET; RIFLE; etc.

GEORGE H. POWELL.

Fire-back, or **MacCartney Cock,** any of the small Malayan pheasants of the genus *Acomus*, or of the Indo-Chinese genus *Lophiura*, in which the plumage of the back or rump displays glowing metallic reds. The rest of the plumage is very gorgeous, especially in the cocks, which, in *Lophiura*, are adorned with a magnificent crest. See PHEASANT.

Fire-balloon, a balloon whose ascensional power is derived from a body of heated air rising from a fire beneath the open mouth of the bag.

Fire-balls, (1) Balls filled with powder or other combustibles, intended to be thrown among enemies, and to injure them by explosion, or to set fire to their works. (2) A popular name applied to a certain class of meteors which exhibit themselves as globular masses of light moving with great velocity, and not unfrequently passing unbroken across the sky until lost in the horizon. They differ from ordinary meteors, probably, more in volume and brilliancy than in any other distinctive characteristic. They are not to be confounded with another class of meteors, that explode in their passage and appear to let fall a dull-red body (meteorolite) to the earth. See METEORS.

Fire-bar, a grate bar in a furnace resting on a frame, called the fire bar frame; inside the fire box in a locomotive engine, wedge-shaped iron bars fitted to the fire box with the thick side uppermost, to support the fire; the ends rest on a frame; they are inclined inward, with an air space between each, to promote combustion, and are jointed at one end, and supported by a rod at the other, so that the rod being withdrawn, the bars fall, and the fire box is emptied.

Fire-bellied Frog. See FIRE-TOAD.

Fire Boat, a small steamboat equipped with apparatus for extinguishing fires that may occur on the wharves or among the shipping. Used in many large cities, they have proved of great service. See FIRE PROTECTION.

Fire-brick, a brick capable of sustaining, without fusion, the extreme action of fire. They are used for lining furnaces, and for all kinds of brick-work exposed to intense heat which would melt common bricks. They are made from a natural compound of silica and alumina, which, when free from lime and other fluxes, is infusible under the greatest heat to which it can be subjected. Oxide of iron, however, which is present in most clays, renders the clay fusible when the silica and alumina are nearly in equal proportions, and those fire-clays are the best in which the silica is greatly in excess over the alumina. When the alumina is in excess, broken crucibles, glass-house pots, and old fire brick, ground to powder, are substituted for the common siliceous sand used in the ordinary processes of brick making, but which, in this case, would be injurious, as having a tendency to render the clay fusible. Fire-clay being an expensive article, it is usual, when making fire brick at a distance from mines, to mix with it burnt clay, for the sake of economizing the clay and diminishing its contraction. See BRICK.

Fire Brigades. See FIRE PROTECTION.

Fire Chief or **Marshal,** an officer in some of the larger American cities who has the supreme command of the fire department of the municipality, and who directs the work of extinguishing fires. He is generally clothed with large powers of discretion, and has also police authority.

Fire-clay is distinguished from ordinary clay by its refractoriness and infusibility, which render it an excellent material for bricks, crucibles, glass pots, retorts, and similar vessels which are to be exposed to a constant and very high temperature, at which ordinary bricks and clay vessels would fuse and become vitrified. This difference is due to the purity of fire-clay, or at least to the absence from it of iron, lime, magnesia, and alkalies, in appreciable quantities. It consists of hydrated silicate of aluminum almost entirely, but may contain traces of organic matter, and of some of the bases mentioned above. Fire-clay belongs to the coal formation, and always forms a stratum immediately below the coal. It seems, indeed, to be part of the soil on which the coal vegetation flourished and died. See also CLAY.

Fire-damp, the name given by coal miners to carburetted hydrogen or marsh-gas, CH_4. It is an inflammable gas, lighter than air, and is often found in coal mines, it being one of the products of the retarded decay of plant remains. A mixture of fire-damp and air in certain proportions is highly explosive; hence many frightful disasters with great loss of life mark the history of coal mining. See COAL MINING; METHANE; SAFETY-LAMP.

Fire-drill, a term introduced by Tylor to describe the instrument used by peoples of low culture, especially the Australians and Tasmanians, for producing fire. They take two pieces of soft dry wood; one is a stick of about eight or nine inches long, the other piece is flat; the stick they shape into an obtuse point at one end, and, pressing it upon the other, cause it to revolve quickly between both hands. By this method fire is produced in less than two minutes. See FIRE-MAKING.

Fire-eaters, in United States history, the violent, swaggering, and defiant Southern extremists before the War, threatening vengeance on Northern interferers with slavery or government interferers with the slave States. The name is used in a general sense for a blustering hot-head, especially a professional duelist.

Fire Engines. See FIRE PROTECTION.

Fire-escape, the name applied to any means of escape from a burning building. Many suggestions have been made for contriving the means of effecting this, some of them being for apparatus to be used in the interior of a building, and some to be used from without. Of the contrivances to be used within a building the simplest are a rope firmly attached to something near a window, or a rope sliding over a pulley fixed to the window-sill, and the like. And of the different machines that have been made for use from without, that which is found to be the most useful is the one invented by Wivell, and consists of a wheel-carriage supporting a long ladder with a net underneath. The ladder consists of extensions, the main ladder and the upper ladders, the upper folding over the main ladder. When used the ladder is set to the window of a building which is burning; the attendant mounts it, and assists those who are in danger to descend it.

Fire Extinguishers. See FIRE ANNIHILATOR; FIRE PROTECTION.

Fire-flies, any of various forms of nocturnal insects belonging to different orders having the power of voluntary self-luminosity, usually more or less intermittent and exhibited in flashes. After the death of the insects the luminous segments, at least in many forms, can be distinguished by their paler usually yellow color which contrasts with the darker color of the remainder of the insect. The true fire-flies, commonly termed also «lightning bugs,» are found in the family *Lampyridæ*, and particularly in the genus *Photinus*. Throughout a considerable portion of our country, including the District of Columbia and vicinity, *P. pyralis* is the most prominent form of fire-fly. Farther north *Pyractomena borealis* and related species are the more common fire-flies, while a large species, *Photuris pennsylvanica,* extends from north to south. One of the most remarkable forms of fire-flies is found in the genus *Phengodes,* in which the females are wingless and larviform; the males are not luminous. The historic and poetic «glow-worm» is the wingless female of the European *Lampyris noctiluca.* In America the glow-worms are scarce, and are usually the larvæ of the genera which have been mentioned, most of which are luminous in both sexes. In other countries various other insects are reported to have the power of luminosity, among which are the lantern-flies of South America (*Fulgora lanterneria* and *candelaria*). The luminous power of the lantern-fly, however, is doubted. In Central America and the West Indies and in South America the most abundant fire-flies belong to the genus *Pyrophorus*, large snapping-beetles (*Elateridæ*), in which the luminous portions of the body are on the sides of the thorax in the form of two large pale eye-like spots. Numerous other forms of insects, including another genus of *Elateridæ*, an Asiatic buprestid beetle, some forms of poduras, the maggots of certain flies, especially of the fungus gnats (*Mycetophilidæ*), are luminous; but next after the *Lampyridæ* perhaps the myriapods are most remarkable for the possession of this power of self-illumination. The luminous or photogenic organ is regarded by Wielowiejsky and also by Emery «as morphologically a specialized portion of the fat-body, being a plate consisting of polygonal cells, situated directly under the integument, and supplied with nerves and fine tracheal branches»; while Lang, in writing of the physiology of insect-phosphorescence, briefly states that «the cells of this luminous organ secrete, under the control of the nervous system, a substance which is burnt during the appearance of the light; this combustion takes place by means of the oxygen conveyed to the cells of the luminous body by the tracheæ, which branch profusely in it and break up into capillaries.» Emery, writing of the luminosity of females of *Luciola,* states that its use appears to be a means of defense, a warning or danger signal against insectivorous animals, but there is little doubt that it also serves to attract the sexes, especially in the case of the wingless females whose powers of locomotion are so limited, while the males fly freely. Prof. S. P. Langley, secretary of the Smithsonian Institution, has made considerable study of the «cucujo» or *Pyrophorus,* as has also Heinemann, the latter reaching the conclusion that the light depends on a process of oxidation. The cucujos are the most interesting of all the fire-flies, and they are much used by the South and Central Americans in furnishing amusement for the children, while the ladies employ them as ornaments for their evening toilet, fastening great numbers of them to their ball dresses.

The literature of this subject is very extensive, but a list of important articles compiled by A. S. Packard may be found in the 'Journal of the New York Entomological Society,' Vol. IV., 1896.

Fire Insurance in America. Although during the last half century the business of fire insurance has undergone a larger development in the United States than in any other country, it seems, when considered historically, to have been a means of self-protection, which did not readily commend itself to the judgment or confidence of our early predecessors. The expediency, not to say need, of endeavoring by means of co-operative action to minimize the individual loss and suffering incident to the destruction of property by fire made itself felt in England after the great fire in London in 1666, and there is reason for thinking that in a somewhat crude manner the practice of insuring property against possible destruction by fire had obtained years before that time in some of the countries of continental Europe. But although the early dwellers on this continent had given to them, during the 16th and 17th centuries, many serious and painful illustrations of the misfortune which came to those whose property was wholly or in part suddenly destroyed by fire, it was found impossible, before the advent of the 19th century, to arouse any general interest in enterprises of this character.

Joseph Marion, a notary public of Boston, advertised in the 'News-Letter' of that town, on 18 Nov. 1728, his plan of «erecting an insurance office for insuring houses and household goods from loss and damage by fire by the name of the New England Sun Fire Office of Boston,» and 20 years later, in June 1748, published a similar announcement; but the public co-operation needed to make the attempt a successful one does not appear to have been given to him on either occasion. This was the earliest recorded effort made to introduce this method of co-operative protection against losses by fire to the American people. Prior to that time, and for many years after — indeed, until well into the 19th century— it was the common practice in American communities, for the friends and neighbors of a citizen whose house or shop had been destroyed by fire, to give him such sums of money as they could afford to contribute to make good the loss that he had sustained. It was realized that the calamity was one to which all were liable, and that as each in his turn might suffer from a similar visitation, the contribution given was one which would justify the giver in asking for corresponding assistance if, later on, his material possessions were destroyed in the same manner.

Judged of in the light of modern business methods this system of paying voluntary premiums after a fire for the purpose of assisting others appears to be a thoroughly unsatisfactory proceeding; but in estimating its practical value it is necessary to remember, that at that time such wealth as the community possessed was distributed with considerable evenness among its members; that there were no large aggregations of property which were liable to be destroyed by a single fire, that in these relatively small American towns the financial resources of each citizen were reasonably well known to all of his fellow citizens so that there could be no deception as to possible suffering, and that the people were much more nearly than at the present time bound together by homogeneity of race and interests. These conditions may partly explain why it was that the American people, in spite of the English experiences in fire insurance, and of their own practices of insuring vessels and cargoes against loss at sea, could not for many years bring themselves to realize the advantage to them of the system of fire insurance.

In the year 1752, under the instrumentality of a Deed of Settlement, an organization to carry on the fire insurance business was formed in Philadelphia. Benjamin Franklin was one of its active promoters. This, with a local and rival association which was soon after formed, were for many years the only regularly organized fire insurance offices in America. The business carried on by these appears to have been exceedingly limited in its dimensions, although at the time these two offices were established, there were in England quite a number of fire insurance companies carrying on an extensive business and having large financial resources.

Toward the close of the 18th century the need of some form of protection against losses by fire seems to have made itself generally evident in this country. In 1787 the Mutual Assurance Company of New York was organized for the purpose of insuring local property against fire losses. This association was formed under a deed of settlement which was drawn up, as was also the form of policy that the company adopted, by Alexander Hamilton, who was one of the directors. In 1794 the Baltimore Equitable Society, formed on the same plan, was organized in Baltimore, and in the same year the Mutual Assurance Society of Virginia was organized in Richmond. These were all mutual companies, confining their operations to the towns in which they were organized, and even in these restricting their writings to two or three of the least hazardous classes of risk. But from 1794 to 1810 the legislatures of the leading States of the Union gave permission for the incorporation of fire insurance companies on the stock plan, and in that term of years quite a number of these companies were formed in Boston, New York, and Philadelphia.

In the year 1795, after a delay of years, through failure to obtain legislative authorization, the Massachusetts Fire Insurance Company, with a capital of $300,000, was formed in Boston. This company soon after opening its office announced its intention of writing fire risks all over the United States, being in this respect the first American fire insurance company to adopt the method now in general use, of scattering its liabilities to loss by covering the widest possible area of business, a corporate policy which was adopted the next year (1796) by the Insurance Company of North America, which had been incorporated in Philadelphia in 1794. The Boston effort does not appear to have been a strikingly successful one, for after three years of active exertion the company had written only a little over 1,000 policies, or allowing for annual writing, had insured the property of not more than 400 persons. This discouraging progress led the directors of the company to petition and receive permission from the legislature to enter into the field of marine insurance as offering larger opportunities of profit, a class of business from which its Philadelphia contemporary doubtless derived much the larger part of its income. In the case of Boston in the year 1800, when the town had about 25,000 inhabitants, the estimated amount that the various fire underwriters had at risk was but a little over $2,000,000, this probably representing the conditions as they then existed in the other principal centres of population on this continent.

With the opening of the 19th century insurance companies organized to write fire risks were formed in quite a number of the business centres of this country; but for many years the efforts of their officers had to be directed to the work of explaining to the American people the advantages which might be expected to result from taking out fire insurance policies. As late as 1823, the directors of a prominent insurance company issued an address to the public in the form of a printed circular, in which they say that "presuming the subject of fire insurance has fallen under the consideration of comparatively few persons, they trust no apology will be thought necessary" for their publication. They then go on to add: "He who loses his all at sea by not insuring, instead of sympathy meets with reproach for his temerity. He who suffers by fire, although equally chargeable with rashness and imprudence, not only claims exemption from reproach, but appeals with confidence, and often with success, to public sympathy. The distress and misery resulting from this misfortune have been so often witnessed and felt, as to render it unnecessary to enlarge on the subject. It is sufficient to refer to the frequent appeals to public charity. Probably in no country in Europe is there so great a proportion of the property uninsured as in this country. There, more particularly in Great Britain, it is a very general custom to insure furniture and houses as well as merchandise and stores." It will be seen from the above quoted appeal that the need of the protection of fire insurance on business grounds was the basis upon which this now universal custom was first built. As the manufacturing, commercial and trading interests of the States increased in magnitude and value, the manufacturers and merchants were compelled more and more to have recourse for credit accommodations to the banks, which in the last years of the 18th and the early years of the 19th century were established in ever increasing numbers in all of the business centres of this country. The practice then sprung up on the part of the lenders of money of insisting that the borrower should, for the protection of the loan, keep his property insured against loss by fire. This soon came to be a common condition on the granting of credit by the banks. The merchant might be indifferent to loss by fire so far as his dwelling and its contents were concerned; but he was forced by the compulsory action of those from whom he borrowed money to protect his business property from this class of sudden loss. This banking practice was strengthened by the experiences of the great fire in New York in 1835, which destroyed fully $15,000,000 worth of property and strained to the point of insolvency the greater number of the fire insurance companies that were then doing business in that city.

During the early years of the last century the fire underwriters carried on their business, so far as official supervision is concerned, in no way different from the dealers in merchandise; but in 1837 the legislature of the State of Massachusetts passed a law, which has since been adopted by all of the other States of the Union, compelling the insurance companies wishing to do business within their respective boundaries, to first obtain authorization so to do, and second, to file with the State officials, annually or more frequently if requested, a detailed report of their financial condition, the extent of their liability, the amount of premiums received and the sums paid out in losses. It is not improbable that the experience in New York, referred to above, led to the adoption of the plan of State supervision, for that great fire made it evident that a number of the fire insurance companies had been writing risks with a freedom which indicated little or no regard for possible consequences, either to stockholders or policy holders. This form of paternalism then adopted, while in some respects safeguarding public interests, has led in other respects, as will be pointed out later on, to results which are somewhat questionable so far as public advantage is concerned. During the last 25 or 30 years the growth of the fire insurance business of the United States has been in close correspondence with the increase in this country of insurable property, and hence at present instead of not realizing the advantages of this form of protection against loss, it is probable that the American people of all classes have the destructible property that they may own better insured against loss by fire than have the people of any other country.

The business of fire insurance in the United States may be roughly divided into three classes — that carried on, first by the stock companies, second by the mutuals, and third by the factory mutuals. By far the greater part of the risks insured are written by the companies in the first of these classes. As there is no one State in the Union in which all of the fire insurance companies, both foreign and American, carry on a regular business and hence make official reports, it is not possible to determine the exact volume of business transacted. Of the State reports those issued by the insurance superintendent of the State of New York are probably the most comprehensive, and from these compilations it appears that in the year 1902 the companies that were then authorized to do business in that State, almost entirely stock companies, had written risks in the United States to the total amount of $21,320,333,036. This report of the year 1902 did not include the writings of quite a number of stock companies having their offices outside of New York, and carrying on a local rather than a general business, nor did it include, to any great extent, the writings either in New York State or elsewhere, of the ordinary mutuals or the factory mutual fire insurance companies. If these several additions were made it is not improbable that the aggregate writing in this country of all of the insurance companies during the year 1902, would be found to be between $23,000,000,000 and $24,000,000,000, a sum which must represent a very considerable percentage of the value of all the property in the United States that is liable to destruction by fire.

There were in 1902 approximately 150 stock insurance companies that reported to the insurance superintendent of the State of New York. Of these 36 were European companies that had agencies in this country and the remainder were domestic corporations. The tendency in the development of the fire insurance business in the United States appears to be toward concentration under the control of a relatively few large corporations, these located in special financial centres. During the decade of 1871–80, many more fire insurance companies reported to the New York insurance superintendent than reported to that official in 1902, although in the interval the volume of annual writings increased more than threefold. Those American companies that have the largest share in this business are corporations having their chief offices in New York, Philadelphia, and Hartford, the capitalists of the last-named municipality showing an aptitude for this class of business, as clearly specialized as is that of the manufactures of Fall River or Pittsburg.

Under present conditions a stock fire insurance company organized to carry on a profitable as well as safe business has to cover in its writings a widely extended field of operations. One of the large companies of New York which in 1902 reported the value of risks written at more than $1,000,000,000, had only a little over $200,000,000 at risk in the State of New York, the rest being scattered in thousands of cities and towns between the Atlantic and Pacific oceans. To successfully carry on a business of this magnitude and detail requires a carefully arranged organization. By the method commonly adopted the country is divided by State or sectional lines into the desired number of districts, each of which the company places under the control of a salaried official who has his headquarters at some convenient and central point in the designated territory. The duties of this manager or special agent are chiefly those of supervision. The company has its local agents, whose remuneration usually consists of a commission based on the premiums received for risks written by them.

But the desire to secure premiums, upon which commissions can be earned, may lead the local agent to take risks on behalf of his company, that the shareholders of the latter might afterward discover were far from profitable, hence the duty of the special agent is to check this possible recklessness, as his standing with his company superior is determined less by the volume of premiums that the company receives, than by its relatively small loss ratio in the district over which he exercises supervision. The risks written by the local agents have commonly to undergo the supervision of the special or general agent, and the criticism of the supervising officials at the home office before they are permanently accepted; for the ability to judiciously cancel policies that local agents have written is a factor in the line of corporate success quite equal in its results to the ability to secure desirable business.

Under existing conditions the business of fire insurance as carried on by the stock companies is largely speculative in its character. To say nothing of such tremendous conflagrations as that at Chicago in 1871 and that at Boston in 1872 — catastrophes which involved such immense losses as to completely defeat any scientific attempt to establish an average of outgo — the fire losses of the United States from year to year show wide variations. The New York State reports indicate in the experience of the companies covered by it, that the average for a long series of years has been a loss of .48-cents for each $100 of insurance written by the reporting companies, a record which cannot materially differ from the experience of the entire country. When the average loss of the different years is considered it is found that this has varied from .39-cents in 1897 to .57-cents in 1893, for each $100 of insurance that the companies have had at risk. This fluctuation is altogether too great to admit of a satisfactory scientific classification of rates. But even if the gross amount of fire loss maintained a more constant relation than it now does to the amount of insurance written, the adequacy or inadequacy of the rate charged for insuring any particular risk, or class of risks, would still rest in uncertainty because of the great variation in loss on special classes of property.

Almost all of the fire insurance companies doing business in this country keep what they term their tables of experience, upon which corporate policy is largely based. In the case of companies doing a large and diversified business, such loss records must be of great value, and yet it is well known that there is a material want of uniformity in these experiences. The records of one company may show that it has made an extraordinary profit by insuring woodworking risks, while the experience of another company, doing a business of equal magnitude and diversity, may be wholly the reverse of this, and indicate a loss ratio in this class far in excess of the entire premiums received for insuring these risks. While efforts have been made to combine the experiences of a number of the leading fire insurance companies, it cannot be said that the data thus obtained can be depended upon to do more than serve as guides for general action. A property which might for a variety of reasons be considered extremely hazardous in one place,— as, for example, a distillery in a locality where public sentiment strongly opposed the use of intoxicating liquor — might in another district be thought a highly desirable risk for a company to have upon its books. Fires occur with great frequency in consequence of human carelessness and shiftlessness, which are not only individual, but sectional in their manifestation; for as a rule, those in this country who live in the northeastern States are found to be more careful in keeping the premises that they occupy in good order than are those who live in the southern or western States. Then what may be fairly termed the element of luck enters largely into the complications, as it often happens in local experience, where two insurance companies are represented by the same agent, that the loss ratio of one will be exasperatingly high, while that of the other will be phenomenally low, although the agent may have exercised his best judgment in writing the risks for each of the two corporations that he represents. It will thus be seen that in determining the question of cost, that is, what constitutes an adequate rate to be charged for insuring a risk, the fire insurance companies cannot depend as the life insurance companies can, upon fairly well-settled bases of liability. They have nothing that corresponds in scientific accuracy to the actuaries' tables of mortality. The most hazardous risk may never burn, the one which appears least hazardous may be destroyed by fire within a few hours after the policy upon it has been issued, and there has not yet been formulated any generally accepted table of loss averages.

Life insurance companies establish a certain standard of physical health to which those to whom they issue their policy must conform. To those who successfully pass the medical examination which the life companies require, policies are issued at a uniform rate of premium. The companies thus have upon their books insurance upon selected lives, while their rates are commonly based upon the expectance of life of the entire community, including the weak as well as the strong. The fire insurance companies have in all cases their lists of prohibited risks, though there is no uniformity in these prohibitions, for in practice nearly all risks can be insured in one company or another; but they do endeavor to make the rates that they charge correspond to what they believe to be the probability of loss. This, under the most favorable conditions, is largely a rule of thumb, for though schedules for rating mercantile risks and special hazards have been prepared, drawn up as the outcome of combined personal experiences, it cannot be said that these are based upon entirely reliable data. The rates arrived at by these schedules are no doubt far superior to the personal guesses of the earlier underwriters; but they lack in a large degree the scientific certitude of life insurance rates determined by actuaries' tables of mortality. One advantage which has come from the use of the schedule system of rating, in addition to the effacement of personal prejudice in rate making, is the penalization of recognized defects in the risks thus classified.

For example, in the construction of buildings certain bad methods, such as the maintenance of vertical openings through the floors, or in the processes of manufacture the use of explosive or largely inflammable materials, can be prevented if heavy, specific charges are imposed in the insurance rates for such needless hazards. The schedule charges ordinarily made for such defects are presumably greatly in excess of the real hazard, and are intended to bring about correction, rather than an adjustment of rates to actual conditions.

These movements toward uniformity and system are only made possible by the union of the larger part of the fire insurance companies in local and national organizations. The practice of corporate combination, in agreeing on a scale of prices, seems inevitable in a business where the cost of the service rendered can never be predicted in any individual instance, and only roughly so in a great aggregation of instances. A company may receive $100 for agreeing to indemnify a property owner to the extent of $10,000 for any loss by fire that he may sustain during a year, and may not during the term of the policy be called upon for a penny of contribution, the premium in this case representing unqualified profit. But another policy, written under the same conditions, might lead to a demand upon the company for a payment a hundred times greater than the amount of the premium. Thus the speculative character of these transactions, when considered individually, is alarmingly great, and it is only by collective action that it is possible to bring them within the range of a reasonable business system. The necessity of co-operation through combination has been recognized wherever the business of fire insurance has been carried on, in the countries of the Old World no less than in the United States. In this country boards of underwriters have been organized whenever the property to be insured has been sufficient to justify the formation of more than one locally incorporated fire insurance company, or to warrant the establishment of local agencies by a dozen or more insurance companies having their corporate headquarters in other places.

The obvious reason for the establishment of these associations is the need that exists that their members should write such policies as they may issue upon a uniform and determined basis of rate. In some of the States of the Union the creation of insurance combinations for the purpose of regulating rates of premium to be charged for insuring property is prohibited by special statutes; but even in these States the paramount need of common action has led the representatives of the fire insurance companies to accept and use so-called advisory rates prepared by expert underwriters, these nominally selling their advice or opinions to those who care to buy the information. The fact that the general business of fire insurance all over the United States is limited to less than 150 insurance companies, that the largest and strongest of these corporations are members of what is in effect a national organization, make it all but impossible to effectually enforce State statutes prohibiting combinations for the purpose of regulating local transactions; while, as has already been pointed out, unrestricted competition would lead, from the highly speculative character of the business, to very general corporate insolvency.

The large and well established companies that have premium incomes of millions of dollars a year upon which by investment interest can be earned, are in a much better position to carry on the fire insurance business than are the newly organized companies that have not and cannot for years expect to obtain these large incidental sources of revenue. This tendency toward monopoly is strengthened by the now usual system of State supervision, which places a serious handicap on efforts to form new and competing companies, by imposing conditions on these which ordinarily lead to a more or less speedy impairment of capital, a result which is held to justify the public authorities in compelling the companies thus afflicted to discontinue issuing policies. Thus, while the insurable property of the country is constantly increasing in amount and value, while most of the well established companies have greatly enlarged their net assets during the past decade, the number of stock fire insurance companies has not increased and such attempts as have been made to establish new companies have commonly ended in failure.

From the New York State reports referred to above, it is found that for a series of 43 years, from 1860 to 1902 inclusive, the loss rates of all of the reporting companies was 58.87 per cent of their premium receipts, though this included the two great conflagrations of 1871 and 1872. The expenses of the business during the same term of years were 35.12 per cent of the premiums, and the rates of dividend paid to the stockholders of the American companies were on the average 11.14 per cent on the capital of these corporations; this representing a liberal return, when it is taken into account that many of the successful companies have, in addition, set aside large sums of money to increase their surpluses. It is quite possible that the cost of the business, amounting in the case of the 145 companies that reported to the New York superintendent in 1902, to $66,286,000, is excessive, and that in time this will be cut down, as it represents a great many million dollars paid out in commissions to brokers, who in modern business economy may be looked upon as needless factors, and who would doubtless be dispensed with, if it were not for the competition to get business that now exists between the companies. The amount of fire premiums received by these companies in the year 1902 was $245,563,426, making the charge $1.16 for each $100 of insurance written. The fire losses paid by these companies for the same year amounted to $94,176,595.

It is the business practice of all of the companies that insure fire risks in this country to insist that the assured shall either insure his property to eight tenths of its value or shall pay an increased rate for the protection that his policy gives to him. This rule does not, however, apply to dwellings and their contents which are ordinarily considered an exceptionally desirable class of property to insure.

The usual term of a policy is one year. If written for a shorter time the rate charged is considerably higher than what would be the pro rata of the annual rate. In the case of buildings, and dwellings and their contents, it is often the case that policies are written for a term of five years, the rates in these cases varying, according to local custom, from three to four times the annual rate. In Philadelphia, and possibly elsewhere, the custom has been in use for many years past of insuring dwellings by what are called perpetual policies, the company insuring these agreeing, in consideration of a capitalized payment of premiums, to insure the property forever without calling for a further contribution on the part of the assured.

When compared with other countries the aggregate of annual fire loss in the United States is exceedingly large. Although there are not accurate statistics either here or elsewhere, it is safe to say that the yearly fire loss of this country is greater than the combined fire losses of the United Kingdom, France, Germany, Austria and Italy. This exceptional experience is due to our defective building laws, to the poor enforcement of those that we have, to the greater recklessness of our people, and to the tendency to accumulate large values in merchandise in buildings of great and undivided areas, thus permitting one fire to damage or destroy property worth enormous sums of money. That this record of loss is to quite a degree needless, or at least preventable, is shown by the experience, given later on, of the factory mutual fire insurance companies. So far as the influence of the underwriters connected with the stock fire insurance companies of America has been brought to bear in the direction of reducing fire losses, it has been of public value; but it is possible that collectively they have not yet exerted themselves along these lines to the extent that they might or as they may find it expedient to in the years that are to come.

Considered in its broader aspect, all fire insurance is carried on upon the mutual basis, for the stock companies do not intend to pay fire losses from their capitals, which are held as reserves to meet some great catastrophe. The stock underwriter collects premiums from a large number of property owners and uses these for the purpose of paying the fire losses which come to a few of those whom he insures. Under the purely mutual system the companies have no capitals belonging to stockholders, for all of the corporate assets are the property of the policy holders for the time being, who when they take out their policies obligate themselves to pay upon demand, in addition to whatever premium they then pay, such further sums as may be necessary to make good their share of any exceptional loss that the company may sustain, this contingent liability being usually limited so as not to exceed two, three, or four times the sum of the original premium. If the business transactions of the company are carried on upon a low loss ratio, the profits, after deducting the expenses and salaries of the company officers, are paid back to the policy holders in proportion to their original premium contributions.

This is an entirely equitable method, and when the business carried on is confined to isolated risks of a non-hazardous character, the result has frequently been eminently satisfactory. By this means the expense of fire insurance has been reduced to what it has actually cost, and when limited to a few classes of risks, such as dwellings and their contents, or unexposed buildings occupied for stores and dwellings, it has been possible to establish rates of premium which have been reasonably fair to all participating policy holders. When, however, the mutual method has been more widely extended, so as to take in a great variety of risks, the possibility of very large losses, and the uncertainty of whether each policy holder has contributed his fair and proper share to the general fund, has militated against the efficacy of the plan, and in many instances has brought about the bankruptcy of the too adventuresome corporation. There are successful companies of this mutual type to be found in all parts of the United States, but for obvious reasons their range of business is greatly circumscribed.

The system of fire insurance applied by the so-called factory mutual companies is a distinctly American outgrowth of the ordinary mutual method of providing indemnity for fire losses. The first company of this type established was the Providence Manufacturers' Mutual Fire Insurance Company, which was incorporated in 1835; but there are now 19 companies of this class in the eastern section of the United States, and others which somewhat correspond to them in the South and in the Mississippi valley area. These companies were the outgrowth of the belief on the part of certain manufacturers that the stock companies were charging for insurance protection unwarrantably high rates, and that it would be better for these manufacturers to try the plan of insuring each other. If they had restricted their services within the then understood range of insurance work, their operations would not have been attended with material consequences. But from the outset, and with increasing earnestness as time has gone on, the officers of these companies have insisted, that the duty of paying fire losses was only one, and the less important function which these companies had to perform, and that the work of preventing fire losses was the service to which attention should chiefly be given.

The results which a consistent enforcement of this theory have secured, have been unparalleled in the experiences of fire insurance, either in this country or elsewhere. The risks protected by the policies of the factory mutual companies would be ordinarily classed as specially hazardous. Cotton, woolen, and paper mills, rolling mills, iron foundries, and the like, are not hazards that the stock underwriter ordinarily views with favor, and yet as the result of thorough, periodical inspections, of bringing to the attention of the manufacturers the advantages of certain improvements and of securing the cooperation of the latter in introducing and applying these, the probability of fire loss in these risks has been brought down nearly to the level of the fire hazard in ordinary dwelling houses. In the year 1902 these 19 companies issued their policies to the gross sum of $1,080,468,237, and on these paid a total fire loss of only $654,170. The experience of some of the companies was relatively better than would appear by this showing. Thus the Boston Manufacturers' Mutual Fire Insurance Company, of which Edward Atkinson is president, gave their average cost of insurance per $100 per year for the three years 1900–02, at 7.36 cents. The significance of this showing is brought out by recalling that while practically all classes of property in this country, as determined by insurance rates, are much more liable to fire loss than similar property in Europe, the mills in the United States under the factory mutual system show a smaller average fire loss than any similar risks in any other part of the world.

The obvious deduction to be drawn from this showing is that by combining fire insurance with supervision of risks it is possible to reduce the enormous fire waste of the United States to reasonable proportions. The lesson taught by the factory mutuals has not been overlooked by the stock companies, which have, when it has been possible, applied a similar system of inspection to the risks which they have written. The disadvantages which they labor under are that risks which they take are not usually under a single control or ownership, are not isolated or unexposed by other hazards, and in most instances have such a restricted value that the entire fire premium would not be sufficient to pay the expense of careful periodical inspections. But with the larger risks the system of frequent inspections is quite generally applied, while the increasing use of automatic fire sprinklers — the most effective fire preventive device ever invented — and the scientific regulation upon safe principles of all new mechanical devices by the Underwriters' Laboratory which the stock companies have established, give promise that in the future the needless losses by fire will be greatly reduced in number and volume to the great ultimate benefit of all classes of insurers.

Osborne Howes,
Boston Board of Fire Underwriters.

Fire Island, the most westerly end of a strip of the Great South Beach, Suffolk County, New York, 40 miles long, averaging one half mile wide, off Long Island, between Great South Bay and the Atlantic Ocean. It is reached by ferry from Babylon. The beach took its name from the fires built there as signals to vessels during the war with England in 1812. Between the beach and the mainland, in Great South Bay, are five small islands. About 45 miles east of the inlet to the bay Great South Beach joins the mainland. The entire strip is dotted with popular watering-places; the air here is said to be a specific for hay fever. There is a large hotel on Fire Island Beach, and within a few rods to the east a lighthouse 185 feet high with a revolving light. Margaret Fuller Ossoli, her husband, and child, were drowned on this beach 19 July 1850.

Firelock, a musket or other gun, with a lock furnished with a flint and steel, by means of which fire is produced in order to discharge it; distinguished from the old matchlock, which was fired with a match. See Musket.

Fire-making, the art of producing fire. It was believed by the ancients that man was without fire till Prometheus stole some from the chariot of the sun, but the whole story has a mythical look. Plutarch says that in his time there were fireless races of mankind, and the geographer Pomponius Mela indicates Ethiopia as the locality of one of these. A certain Eudoxus, however, taught them how to produce it. This story cannot be tested now, but Edward Tylor, after passing in review the alleged modern instances of fireless races, rejects them one and all. He believes that there was a time when man was without fire, but it now everywhere appears to have passed away. The oldest method known of making fire is the South Sea Island one by means of a stick and a groove. There followed next, it is believed, the method of striking fire by means of a flint, a piece of iron pyrites and tinder. This process was known to the ancients, which is the reason why they called one of the two minerals used pyrites — that is, fire-stone. The Greeks, in the time of Aristophanes, knew how to concentrate the sun's rays by a burning-glass, and the Romans in the age of Pliny (23–79 A.D.), effected the same result by concave mirrors. In the case of the need-fire, a superstitious rite connected with sun worship, and of which an instance occurred near Perth as late as 1826, fire was obtained by the revolution of a windlass in the hole of an oaken post smeared with tar. The preceding generation remembered the time when fire was obtained by flint, steel, and a tinder box, till superseded by the lucifer match.

Fire Philosophers, certain religionists, who in the 16th and 17th centuries attempted by the aid of fire to penetrate to the primary elements of things. They attributed little to human reason and reflection, but nearly everything to experience and divine illumination. One of the most notable among them was Jacob Boehme, a shoemaker, of Gorlitz, whom his patrons called the German theosophist. He lived in the 17th century. The others were also called theosophists.

Fire Protection, the means employed toward extinguishing fires once they are under way, which is quite distinct from avoiding the outbreak of fire, the latter being termed "Fire Prevention." The scourge of fire has been feared, and combated by different methods, and with varying degrees of failure and occasional success, since the early ages. Water has been the almost universal extinguishing medium employed. In fire protection the theory of combustion is an important matter for consideration. A substance "burns" when its temperature has been raised to or above its ignition point and provided it is in the presence of sufficient oxygen to support the combustion. The burning of all so-called inflammable substances, or those having a comparatively low ignition point, acts to quickly raise the temperature of similar adjoining substances to a point where they in turn burn, thus continuing or spreading the fire. In fires which concern the protectionist, the required oxygen is supplied from the air, and combines with the inflammable substances at their varying ignition points. The resultant chemical action produces heat and fire results. This action also produces gases which, when burning, constitute flame, the smoke consisting of particles of the material which have not been consumed, which are borne away by the hot air currents. In subduing a fire, one of two courses may be pursued, namely, to reduce the temperature of the material below its ignition point, or to exclude the air. The importance of checking the spread of fire in its early stages cannot be overestimated, and to-day all intelligent effort is directed to this end; otherwise, such an amount of combustibles may become afire at one time as to quickly overtax all fire fighting facilities which the most prodigal would provide. To illustrate: one pound of wood fuel will evaporate about one gallon of water. There are in this country innumerable buildings, each containing tons of combustible material, and, should a considerable part of any such building and its contents become afire, it can be readily seen that the thousands of gallons of water per minute necessary to reduce the temperature of the mass below its ignition point would seldom be available, particularly if combated through hose streams, as it is generally conceded that but a small portion of the water thus thrown ever reaches the seat of a fire. This waste is variously estimated at from six tenths to nine tenths of the water discharged. The loss of efficiency is due to the impossibility of approaching closely to the seat of a fire once it has gained good headway. Smoke, heat and flame prevent by holding the fire fighters at a distance and by concealing the precise location of the fire; yet the water must penetrate the smoke and flame and reach the heart of the fire before the temperature can be reduced sufficiently and the fire extinguished. It is, therefore, important to bend every energy toward assailing the fire during the early moments of its existence, and to realize that many buildings once thoroughly aflame cannot be saved by the most powerful facilities known. In such events, the fire department's chief occupation must be the saving of adjoining properties, thus preventing spread of the fire. Conflagrations and large fires represent conditions where blame should attach for allowing a state of affairs which makes them possible, rather than that they are not successfully combated when once under way. In the United States, the inflammable construction and large areas of buildings have compelled advanced fire protection, which is particularly noticeable in the highly organized, quick acting public fire department, and the even more rapid automatic sprinkler equipment — the latter is the most efficient known method of fire fighting. Both systems have received their chief development in this country.

Up to the 18th century, special and efficient types of fire apparatus were not in general use. It is true that Hero, about 150 B.C., describes the construction of a small two-cylinder, single-acting, hand-brake, force-fire-pump, and Pliny speaks of force pumps used in fire extinguishment. Apparently, such pumps were little used, but their early origin is most interesting. Syringes, or "squirts" discharging water — some of them large enough to require several men for operation — seem to have been used by the ancients and up to the 19th century. Chemical extinguishers of slight efficiency were used in the 18th century, as for instance, hollow clay balls containing powdered alum and a charge of gunpowder connected with a fuse, all of which was to be thrown into the fire. The hand-pump, draughting from a trough of water, mounted on wheels, was in use in England, Germany, the United States, and elsewhere during the middle and latter part of the 18th century, and represented the first machine of importance, having an extinguishing power radically in excess of the public bucket brigade. This type of apparatus was developed into the well-known hand-brake, which was the immediate forerunner of the modern day steam fire engine. The first of the latter was built in London 1829, and the first in the United States in 1853.

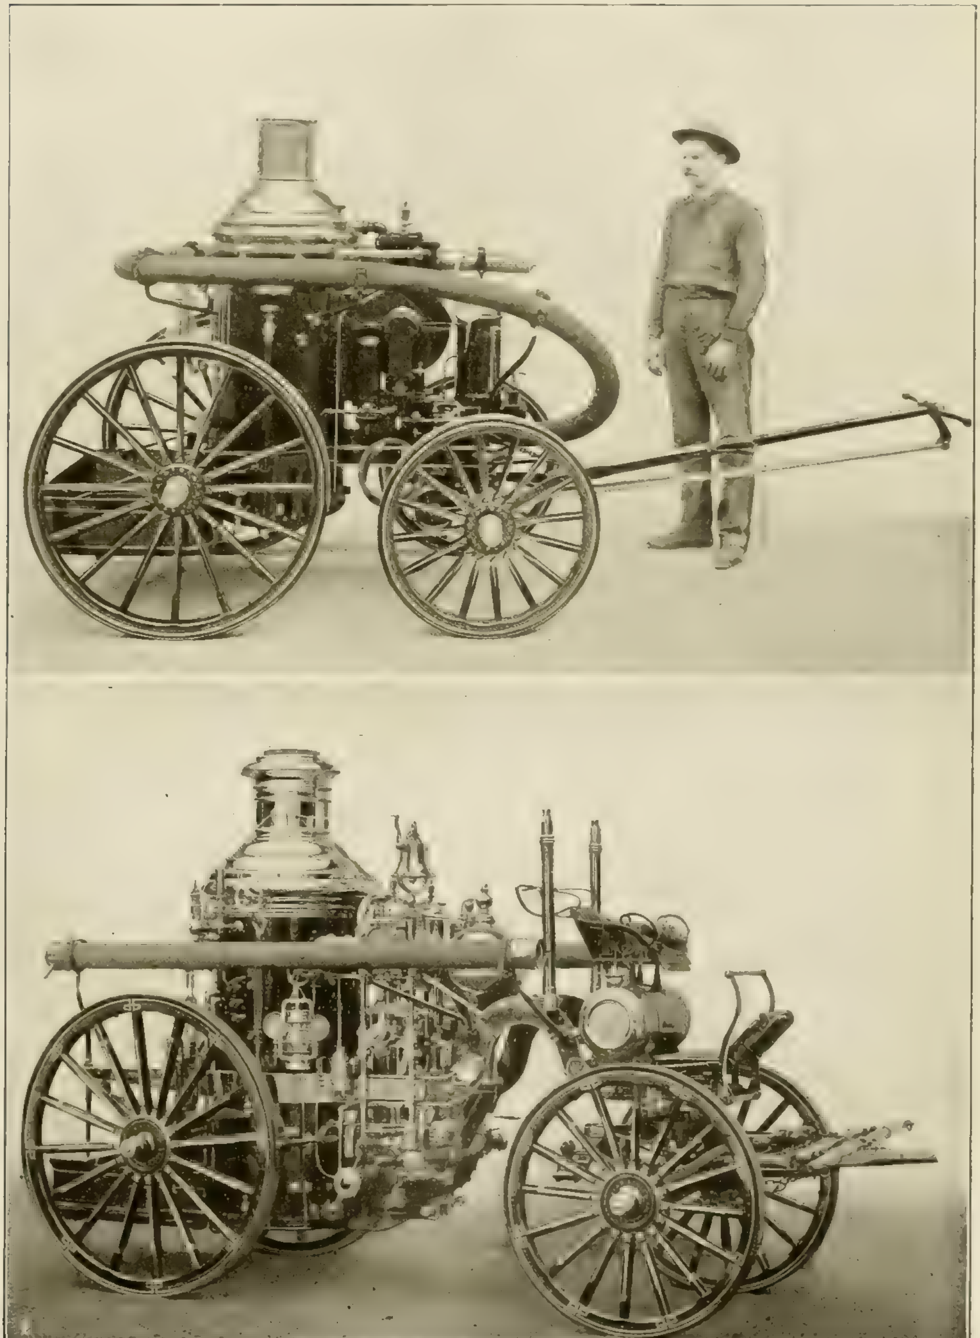
In all this time water has constituted the only extinguishing means of any importance and has been put into use chiefly by the hand-pail or bucket, the hand-pump and the stationary or mobile steam-pump.

It should be pointed out that all devices and materials used for fire extinguishment, many of them consisting of more or less complicated mechanism, possess the great disadvantage of not being in constant or daily use, as is, for instance, the machinery of a mill used in the daily production; and when called upon are liable to be used immediately, without time for preparation and up to the maximum efficiency,— perhaps also by those unskilled in their manipulation and laboring under excitement. It is, therefore, necessary that all such be designed and built, not only in a manner which would be adequate under normal working conditions, but with a much wider margin of safety and excess of strength and excellence to provide for such abnormal demands. It is important that proper rules be framed for the construction, installation and care of all fire protection devices, and, in the United States this work, so far as private fire protection is concerned, is carefully specified by the National Board of Fire Underwriters, who maintain extensive laboratories for such purpose.

Public fire departments have been developed in this country to a remarkable degree. The scope of the organization and the types of apparatus to be employed are to be determined by the area, height and character of the buildings to be protected and the nature of the water supplies available. The apparatus of a public department usually consists of steamers, fire hose and play pipes carried on carts and laid in folds for quick removal, ladders for gaining access to the various floors and roof of a building from the exterior (these include extension ladders operated by hand, hydraulic, steam and electric power), chemical engines drawn by horses and discharged through lengths of hose carried into a building in same manner as the larger hose streams from the steamers, hand chemical extinguishers of the carbonic acid gas type, water towers for projecting powerful hose streams within a building from points opposite upper story windows, and also numerous and varied minor and subsidiary devices. All effort is made to bring the department into action on the scene of the fire at the earliest possible moment, to which end are used the electric fire alarm systems, both automatic and manual. Quick hitching apparatus is employed for almost instantaneously adjusting harness to the horses in the houses in which the apparatus is maintained. The horses are trained to take their places at the pole on alarm of fire, at which time an electric device releases their stall fastenings. The main doors are opened by the operation of a release mechanism, and the firemen sleeping on the floors above the apparatus have their garments so designed and arranged that, in event of a night fire, they can clothe themselves almost instantly, and, descending to the main floor by sliding poles, take their positions on the apparatus and emerge from the house in a few seconds. In thus promptly reaching the fire, and giving it little chance to extend beyond the point of control, our public fire service deserves greatest credit.

One portion of the apparatus above mentioned must be specially pointed out as regards its efficiency. From 50 to 75 per cent of the fires of record controlled by public departments are to-day extinguished by the small chemical engine, whose great efficiency in the hands of a

FIRE ENGINES.



1. Small Fire Engine for a Country Place.
2. Engine for a City Fire Department.

fire department is due to the fact that the apparatus is light, and in responding to a fire is prompt in arrival. The hose is small and easily handled under the extra high pressure which prevails and hence is the first to be taken into the building, reaching the scene of the fire early enough in most cases to bring about the remarkable percentage of successes above noted.

Discipline and thorough training and organization of a department are of utmost importance, and it is a great regret that these do not prevail in all places. The rank and file of American firemen are well above the average as regards bravery and intelligence, but can never be brought into a satisfactory state of efficiency until politics have absolutely no influence in the organizations.

Pails.— Galvanized iron, of 12-quart capacity, are generally used, either round or flat bottom, the round being designed to prevent the pail being set down on the floor or commonly used, that it may thereby be reserved for fire purposes only. Metal covers may be used to keep out lint or dirt. They are to be hung on posts or set on shelves at frequent intervals throughout a room and kept full of clean water. In places where quantities of paints, oils, grease, etc., are used, or in electric stations, at least a portion of the pails are to be filled with dry sand. Complicated sealed-top pails filled with unknown solutions are not advised. Fibre pails or wooden pails are not apt to last as long or be as desirable as those above recommended.

Casks.— Stout wooden or metal casks to hold a reserve supply of water are useful in conjunction with pails or buckets. A quantity of lime may be slacked in such barrels, and common salt dissolved therein to retard fouling in hot weather, or freezing during the cold months.

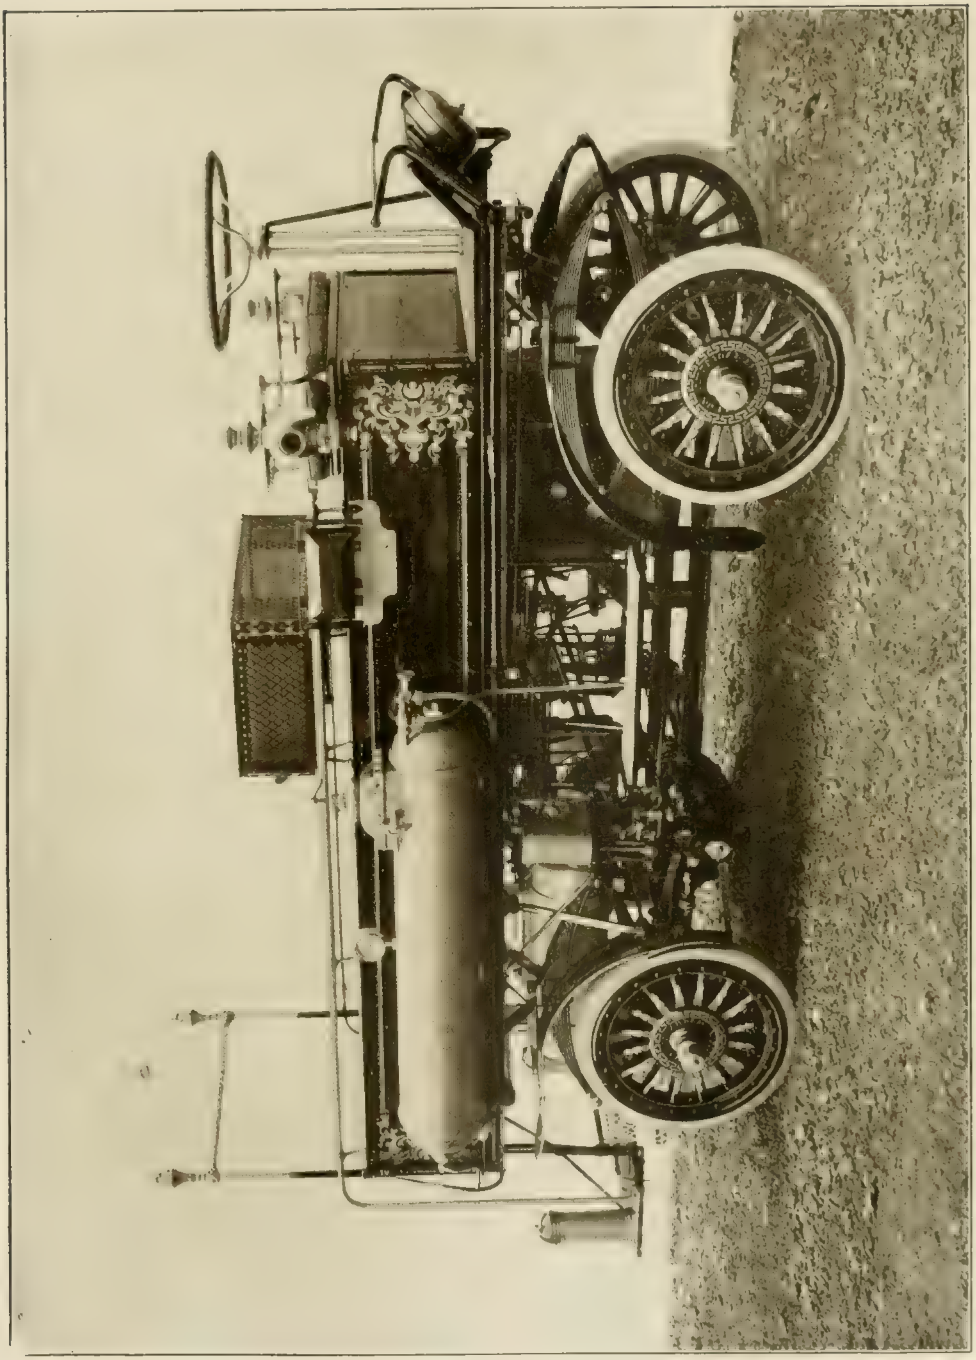
Flexible hose as used for fire protection was invented by Jan Van der Heide, of Amsterdam, in 1672. It was made of leather with sewn edges. About 1808, a Philadelphia manufacturer improved this method by using copper rivets in lieu of sewing the seams. Fire hose of hemp was made in Germany in 1720. Leather was, however, generally used until rubber hose was introduced in England in 1827, and for many years after until replaced by the modern woven, or knit-cotton, rubber-lined hose. For private hydrants, 2⅝-inch cotton rubber-lined hose of best quality should be used. The underwriters' requirements enter into most minute particulars as regards the construction of this hose, and only that tested and "approved" should be purchased. For public fire department use, hose of 2½-inch to 3-inch, either cotton rubber-lined, extra jacketed, or the all rubber type is used, as this hose is subject to rough and frequent usage. Hose used within a building on standpipes should be of best quality woven linen, from ¾-inch to 1½-inch in diameter, frequently connected that lengths may be short. Smooth bore brass nozzles of ¾-inch diameter should be used for this hose, and it is preferred not to connect large diameter hose within a building, the small, so-called "hand-hose" being light and easily manipulated by the inexperienced even under high pressure, and if abandoned, as inside hose often is, does not leave a large quantity of water running to waste. Play pipes for 2½-inch hose and larger should have perfectly smooth tapering tubes, and there are precise specifications for the underwriters' type, which, briefly described, is 30 inches long, wound and painted, has swivel handles at its base, and is provided with a 1⅛-inch smooth bore tip or nozzle. In places where the temperature falls below freezing even for a short time and at rare intervals, only the best quality frost-proof hydrants should be used, these to be of "post" pattern, that is, extending above the ground where they are instantly available for operation and hose connection. The refinements of hydrant construction are specified by the underwriters, and a material improvement in their construction is being effected at the present time. Water discharge outlets, called "monitor nozzles," connected directly with the supply piping without the intervention of hose are often advised, as at roof locations. They are arranged to be revolved by hand and the nozzle raised or lowered. For most practice, tar-coated, cast-iron pipes should be the only type used for underground work. Wrought-iron pipe when laid underground, deteriorates much more rapidly, aside from being more difficult to keep tight at the joints. Much cast-iron pipe on the market is imperfect, and very likely has been discarded by large purchasers who make careful tests. It is, therefore, important that such pipe should be most carefully specified and built in strict conformity with the requirements of the underwriters. Furthermore, much good pipe is injured in shipping or unloading, and, perhaps the most important feature of all is in laying and calking, which should always be entrusted to men experienced in this line of work. All such pipe systems should be submitted to a searching hydraulic test after completion, the precise procedure for which is minutely laid down by the underwriters.

Public Water Supplies.— The most reliable and satisfactory method of obtaining water for extinguishing fires, either through the medium of hose streams or automatic sprinklers, is the reservoir, inexhaustible under both domestic and fire consumption, of unfailing supply in season and out, and of sufficient elevation to give the required hydraulic head. Many buildings in a majority of towns, villages and cities require for satisfactory service a pressure of not less than 75 pounds at grade, this pressure to be taken with the water flowing. A standard hose stream for general use is one flowing 250 gallons per minute through a 1⅛-inch smooth nozzle. It is important that the number of full-capacity hose streams necessary at any one time be predetermined and their existence or non-existence established by actual test, namely: Flowing water simultaneously through the required number of streams to determine whether under such conditions the pressure requisite can be maintained. Such a supply not being available in a majority of instances, recourse is had to one of the following systems: Gravity supply from elevated reservoir or standpipe of limited capacity, fed by pumping engines, direct pressure service from pumping engines, or a combination of gravity feed and direct pressure. It often occurs that a gravity supply is adequate for domestic purposes, but the pressure therefrom needs to be radically increased in time of fire by pumping directly into the mains, or, it may be that the pressure from gravity supply is adequate for a portion of the town, but that, due to area and height of buildings or elevation of land, high pressure is required for another portion. It is manifest that a gravity supply is more reliable than supply from pumping engines, other conditions as to pressure and quantity being equal. This is due to the occasional necessary interruption of pump service and holds true except where a number of separate pumping units are maintained, each adequate to the service required. An important precaution rarely taken is the location of such pumps in strictly fireproof buildings and where not subject to damage by exposure to fires. The modern city building of excessive height and area has created a demand for fire protection and water supplies not previously contemplated and which existing systems are quite unable to meet. This is being provided for by special high-pressure pipe lines, often of special design to provide against leakage and breakage, fed by pumps capable of discharging their rated capacities at high pressures, generally at about 300 pounds. Such systems are now to be found in Boston, Buffalo, Chicago, Cleveland, Detroit, Milwaukee, Philadelphia and Providence. In most cases the fire boats serve these mains, but in Philadelphia there is a fireproof pumping station in which numerous force pumps, each operated independently by its individual gas engine, are located. This station is used only for supplying the high-pressure fire service, at about 300 pounds pressure. The pipes for this system were submitted to a foundry test of 800 pounds per square inch. The use of gas engines for this purpose is a novelty, and have been resorted to for economy of maintenance as compared with the steam plant. The gas engines can be started to full capacity in a few minutes, and, as this high pressure service will be called upon but a few times per month, it will be seen a material saving is effected in cost of maintenance. Salt water from the sea is desirable for fire extinguishing purposes, and has theoretically a slightly greater fire extinguishing value. Being a never failing and inexpensive source, it should wherever available be made use of for high-pressure fire service systems.

Steam stationary fire pumps for factories and private protection generally, should be duplex, and of the type which is most carefully specified by the underwriters. While these pumps may not be economical for constant service — they are not built with such intention — they will be found staunch and fully efficient for an emergency run at time of fire. They are generally made in four sizes and are rated according to the number of gallons to be discharged per minute under average conditions, namely: 500 gallons, 750, 1,000, and 1,500. Where larger capacities are desired, they should be secured by the use of two or more such pumps. Special care is taken in their design to have the areas and passages of ample size and to make the pump proof against such rust as could cripple its operation and of substantial design. Automatic governors can be inserted in the steam supply of such pumps, causing the pump to maintain automatically a predetermined water pressure in its discharge pipe. A more modern arrangement for this purpose is a small pump auxiliary to a larger fire pump, each fitted with an automatic regulator, but the smaller one set at a higher point so that it takes up all of the slip and wear and tear of operation except in event of fire, when, unable to maintain the pressure in view of the increased demands, the larger pump comes into play for such purpose. Portable steam fire engines are commonly used to provide pressure and quantity of water desired for fire streams when both these factors are not found existing in the public water service. They are called "steamers," being designed to very rapidly "get up steam" sufficient to operate the engines driving the water pumps. Their capacity per minute is commonly rated as follows: 1st class, 900 gallons; 2d class, 700 gallons; 3d class, 600 gallons; 4th class, 500 gallons; 5th class, 400 gallons. They are generally drawn by horses, although a number of steam driven machines have been in satisfactory use for many years. In such machines, by a change of gearing, the engines used for propulsion are, upon reaching a fire, disconnected from the running gear and used to operate the water pumps. They are built to discharge as high as 1,400 gallons per minute.

To bring the water to the seat of fire from the source of supply with as little friction loss as possible, much care is required, not only in having the pipes of sufficient size, but also that they shall be fed at proper points and connected in a general net-work or "gridiron" to prevent dead-ends. It should be clearly borne in mind that the very frequent location of hydrants is, in the long run, very much less expensive than the reverse policy, as the latter would involve the purchase and maintenance of much larger supply of hose, the latter being perishable and costly. The greatest amount of expert supervision is necessary in the laying of such pipe systems that they shall be correctly installed so as to give a minimum percentage of leakage, to prevent foreign matter entering the pipes while being laid, and constant care is required thereafter that buried gate valves may be kept wide open and all portions of the system free from obstructions.

Fire Alarms.— During 1852, in Boston, the first fire alarm was transmitted electrically from a central office to the nineteen tower bells of the city. Two years previous the Morse telegraph had been used in New York for sending notice of fire from police stations and engine houses to watchmen stationed in bell towers. The modern system consists of numerous street boxes which can be instantly operated by any citizen who desires to announce a fire in the vicinity. This alarm is electrically transmitted to a central station, and from that point to such of the fire department houses as should respond to a fire in the district indicated. Thermostat or automatic fire alarm systems are now extensively introduced and extend this principle of electric fire alarm transmission into and throughout a building. The thermostats, which are small devices for opening or closing an electric circuit as the case may be, are distributed about on the ceiling and wired up to a certain point where they are connected with gongs for the local announcement of fire or direct connection is made with the central station through which the public department is summoned. These thermostats are commonly set to operate at some 150° F. It will, therefore, be seen that they can be affected by the heat rising from a very small fire, and thereby summon the department, perhaps a mile distant, who often arrive upon the scene while the fire is still small enough to be extinguished by a few pails of water.



AUTOMOBILE CHEMICAL ENGINE AND HOSE CARRIAGE.

Open Sprinklers.— Where it is desired to wet down the exterior surface of a roof or side wall of a building to guard against heat from exposing fires, an arrangement of open sprinklers may be provided, consisting of piping to which open valve sprinklers are attached, the piping being fed by the water supply normally kept out of service by a closed gate-valve, which, in event of need, is opened by hand, and the water allowed to issue from all of the open heads. This is found to be an efficacious arrangement where ample water supply is available and exposure is not excessively severe.

Chemical Extinguishers.— The use of chemicals for extinguishing fires has received a considerable amount of attention from ancient times to the present day, yet it is only recently that a successful and reliable type of chemical extinguisher has been upon the market. Numerous so-called fire extinguishing solutions or compounds, claimed to be of mysterious and wonderful power, have been placed before the public, and frequently it is claimed that such a revolutionary extinguisher has but just been "invented." The chemical salts and gases which tend to extinguish fire are well known, and are not likely to be invented at the present day. They consist of the following: Alum, soda, borax, hyposulphite of soda, silicate of soda (water glass), chloride of lime, tungstate of soda, chloride of tin, sulphate of ammonia, chloride of ammonia, sulphate of soda, nitrate of soda, chloride of sodium (common salt), potash, bicarbonate of soda, and ammonia.

To-day the only generally recognized chemical fire extinguisher is the so-called carbonic acid gas machine. It consists of a cylinder, usually of copper, containing bicarbonate of soda dissolved in water, also a bottle containing sulphuric acid. Arrangement is made whereby the contents of the bottle may be emptied into the soda solution thereby instantly generating carbonic acid gas which serves as a propelling agent to eject the soda solution at the cylinder outlet at which point hose is attached. The proportions of acid and soda are arranged so as to allow an excess of the latter. The effectiveness of the stream is, therefore, due to the water discharged on the fire under high pressure, averaging at the start 100 pounds or more; to the carbonic acid gas which, to a considerable extent is carried along with the jet of water, and also to the sulphate of soda deposited by the water jet and which tends to form a crust over a burning surface, this in part excluding the air. The 3- and 5-gallon machines of this type are designed for individual use, 40-gallon machines on wheels are employed for the protection of private property, while the larger 80-gallon machines are the most efficient weapon of the public fire brigade.

Automatic Sprinklers.—Automatic sprinklers afford the most efficient known means of fire protection. They are operated almost immediately by heat from the fire which they are destined to extinguish. This prompt action checks the fire at its incipiency and confines the water to that portion only where it is required. Such effectiveness is in theory and practice all that can be desired. An automatic sprinkler is a small device for distributing water having a valve arranged to be released by action of heat, as from a fire which it is intended to extinguish. The sprinklers are screwed into the outlets of piping, the latter suspended on the ceilings of rooms and filled with water under pressure. It is essential that the sprinklers shall be so located that distribution of water therefrom will cover all portions of the premises; that the piping shall be of sufficient size; that the water supply be of sufficient quantity and pressure and automatic at all times; and finally, that such systems be kept under regular and intelligent inspection. The first device of this nature was patented in England in 1723. Sir William Congreve, in 1812, invented a sprinkler which he described as follows: "An apparatus for extinguishing fires which shall be called into action by the fire itself at its first breaking out, and which shall be brought to bear on the precise spot where the flames exist." Major Harrison, an Englishman, in 1864, invented an improved sprinkler and drew up details for sprinkler installation. In 1874 Henry Parmelee, of New Haven, Conn., patented and installed an automatic sprinkler which was the first practical device of the kind. It was, however, not sensitive, inasmuch as the release joint was in contact with the water which filled the sprinkler and the pipe system. Another step in the art, and one of great importance, was the invention of Frederick Grinnell, of Providence, R. I., in the making of a thoroughly sensitive sprinkler which he did by isolating the location of the release device so that it quickly felt the heat of a fire and operated most promptly. Mr. Grinnell's patents also included a diaphragm valve seat which was self-tightening under increasing water pressure, and also the Grinnell differential dry pipe valve, which devices have since been generally used throughout the civilized world. Realizing the importance, underwriters have made specially exhaustive rules governing the installations of automatic sprinklers, and most carefully test and examine all devices used in such equipments. The installation of a sprinkler equipment in full conformity with the detailed underwriters' rules is a trade in itself. As a basis for the rules, it is required that each automatic sprinkler have an unobstructed outlet of such size and form that, with five pounds pressure maintained at the sprinkler, it will discharge approximately 12 gallons per minute. This is very nearly the discharge through a ½-inch circular orifice in a thin plate. The size of the piping to which the sprinklers are attached is graduated with this discharge per sprinkler as a basis, and also on the assumption that a limited number of sprinklers will come into operation at any one time. This assumption is warranted in view of statistics which show that out of 3,645 fires of record in sprinklered risks, but 5 sprinklers or less were operated in 66.8 per cent of the whole number of fires; 8 sprinklers or less in 76.1 per cent; 20 sprinklers or less in 88 per cent; 50 sprinklers or less in 93.3 per cent. These statistics also show that automatic sprinklers have been introduced in nearly all classes of manufacturing and mercantile buildings, and also in numerous other places, such as hotels, theatres, schools, cold storage depots, etc. Also, that sprinklers have failed to control but 6 per cent of the fires of record, and that these failures summarize according to cause of failure as follows:

	Per cent.
Defective or partial equipment	27
Failure due to water being shut off	24

	Per cent.
Faulty building construction and obstruction	13
Hazard too severe for control	12
Exposures or conflagration	9
Inadequate water supply	7
Water supplies crippled by explosion	2
No watchman	2
Town water out of service	1
Unaccounted for	3

The release principle responsible for the operation of all of the existing approved sprinklers and also a majority of the successful thermostats is that of the fusible alloy, discovered by Sir Isaac Newton in 1799. The sprinkler solder of to-day for ordinary temperatures is marked 160° F., this being the temperature at which the solder granulates or loses its strength. It is composed of: Bismuth, 50 per cent; cadmium, 13 per cent; tin, 12 per cent; lead, 25 per cent. It requires care in making and particularly so in its application to the adjoining metal parts of the sprinkler head. Solders of higher fusing points are made for locations which so require. Sprinklers in use over 20 years under ordinary conditions as to freedom from corrosive influences show on test no change in the fusing point. The stability of the sprinkler solder in this respect is of the utmost value. Once the solder has fused by the heat from a fire, that which holds the sprinkler valve to its seat is removed and the valve opens, either from the spring of the metal parts themselves, or under pressure of water in the pipes. Water then discharges through the sprinkler orifice and is deflected by a splash-plate and distributed in drops over the ceiling and on the floor within the prescribed limitations allotted to one sprinkler. The heads are placed near together on the pipe, generally from 8 to 10 feet apart, and as a rule, covering a floor area of about 80 square feet, the distance varying according to the construction and occupancy of the building and the water supplies, all as precisely stipulated in the requirements. Usually supplies for sprinklers are obtained from the public water service, provided quantity and pressure are ample. Other supplies are elevated gravity tanks, steam and rotary fire pumps, and pressure tanks, the latter consisting of a riveted iron shell resembling that of a boiler, which is filled two thirds with water, and in the remainder an air pressure is created of 75 pounds or more; the discharge pipe to the sprinklers takes out at bottom of tank and the expansion of the air under pressure is sufficient to force all the water out of the tank, the last being discharged under pressure of 15 pounds or more. For best results, it is important that the primary supply to sprinklers be of heavy pressure, 25 pounds or more on highest line of sprinklers, and of sufficient volume to be capable of maintaining approximately this pressure for an ample period with a considerable number of the sprinklers in operation. At least one of the supplies must be automatic on the sprinklers at all times. In addition to the above noted double water supply, a hose inlet pipe is attached to sprinkler systems for connection from hose or steamer of the public fire department, thus allowing the department to make use of the sprinkler piping and heads, the most effective medium through which water can be discharged. Gate valves of prescribed pattern are so located as to control the water supply that it may be shut off for repairs if found necessary. An important adjunct to such a system is a valve which when inserted in the main piping gives an alarm, either electrical or mechanical, in event of a flow of water in the piping. This acts not only to give an alarm of fire, but to notify those interested of any leakage. In places where water within the sprinkler piping would freeze during cold weather, a special "dry valve" is provided which holds the water out of the exposed interior sprinkler piping. By the means of a small pump, air pressure is created within the sprinkler piping which holds the dry valve closed, but is released in event of a sprinkler opening, thus allowing the water to flow in through the dry valve and out through the opened sprinkler. See FIRE UNDERWRITERS. EVERETT U. CROSBY,

Secretary National Fire Protection Association.

Fire-ships are generally old vessels filled with combustibles, fitted with grappling-irons, to hook enemies' ships, and set them on fire. If they are used on a river they are allowed to be carried down by the current, if they are used at sea advantage is taken of a favorable wind to bear them into the midst of the enemy and set their ships on fire. In ancient times the Tyrians employed them against Alexander, and the Carthaginians against the Romans; and during the Christian era the Crusaders made use of them at Ptolemais (Acre). In the time of Philip II. the Spaniards suffered severely by them on two well-known occasions. The first was at the siege of Antwerp in 1585, when by means of fire-ships Gianibelli utterly destroyed a bridge that the Duke of Parma was attempting to throw over the Scheldt, with the aid of some other vessels which he had prepared so as to explode when they reached the bridge. The second case was when Lord Howard of Effingham used them with such effect against the Armada in 1588. In this case also their use is said to have been suggested by Gianibelli. The Greeks in their struggle with Turkey also employed them with great success. In 1857, during the war with the Chinese, whole fleets of such vessels were sent against the British warships, without inflicting the slightest damage.

Fire-toad, or **Fire-bellied Frog**, one of the commoner and more aquatic of the European toads or frogs (*Bombinator igneus*), so called because of the flame-colored patetus upon the bluish-black abdomen. They have many peculiar and interesting habits, and make good use of the colors. "When these toads," says Gadow, "are surprised on land, or roughly touched, they curl themselves into an extraordinary attitude displaying the red of their bellies and throats, and remain so until the danger is past, expecting that the enemy will let them alone after having been shown with what a terrible creature it had to deal." In fact the secretions of the skin are very poisonous, and not even turtles will eat them knowingly. This toad inhabits north-central Europe, and two other species of the genus are known, one in China. It is called "unke" in Germany. Detailed accounts of the animal may be found in Gadow's 'Amphibia and Reptiles' (1901).

Fire Worshippers, the Zoroastrians, called also Guebres. Herodotus, about 450 B.C., said "The Persians think fire to be a god." Strabo, about 50 A.D., said, "They peculiarly sacrifice to fire and water, placing dry wood on the fire stripped of its bark, with fat thrown on it." Rev. Dr. Wilson, of Bombay, alleges that "they actually address it in supplication, as if it were sentient, intelligent, divine, and omnipresent, and ready to hear, bless, assist, and deliver; as is clearly proved by many passages of the Vandidad and by several of the Yasts and Has of the Yacna and Niashes, to be found in the works esteemed sacred and used by the Parsis (Parsees) in their daily prayers." No prominent race now in India has become more rapidly modified by intercourse with Europeans. See GUEBERS.

Fireproofing and Fireproof Construction. The supply of incombustible materials for construction purposes, rather than the rendering of combustible materials fireproof and incombustible by treatment with various chemical substances, has been an important factor in the development of modern building methods.

The subject of fireproofing embraces the manifold plans that have been adopted to erect buildings and repositories for valuable articles capable of resisting the action of fire, and to render wood and textile fabrics incombustible. Among the principal incombustible or fire-retardent materials are asbestos (q. v.), silicate and tungstate of soda, phosphate of ammonia, and borax. A solution of silicate of soda has been found one of the best of the various chemical substances which have been used with the view of rendering wood fireproof. Wood carefully painted and impregnated with this solution requires long exposure to a fierce flame before it becomes charred.

Injections of phosphate of ammonia have been used for fireproof wood in ships with the same fire-retardent effect, but it has been found impossible to render wood absolutely incombustible. After being chemically treated, much greater heat is necessary to kindle it, and its nature is so altered that it burns more slowly, but dampness destroys the effect of the solution, and a beautiful piece of woodwork is in most cases ruined by being saturated with a chemical injurious to its fiber, to the nails and screws holding it together, and to the varnishes upon which depend the beauty of the finished job, and, wherever possible, its use is discontinued.

Among flexible fibrous substances capable of being spun and woven into tissues, asbestos pre-eminently possesses the property of slowly conducting heat, and is largely used for theatre curtains, the padding of fireproof safes, etc. Wool, cotton, and other fibrous matters in common use for the purposes of clothing may be rendered very imperfect conductors by immersion in certain saline solutions, of which sulphate of ammonia and tungstate of soda are most commonly used. The former is cheap, but has the disadvantage of becoming decomposed when the article so treated is ironed. Borax also is very well adapted for rendering articles of dress fireproof, but it weakens the tissue of the material and renders it more liable to tear.

In modern times, a great deal of ingenuity has been applied to the construction of fireproof safes. These are now generally constructed with double walls of stout iron, having a space of three to four inches thick between the walls, filled with some substance which is a bad conductor of heat. See SAFE INDUSTRY IN AMERICA.

In building, the attention of the allied professions of architect and builder has long been devoted to providing materials that will not burn at all. Among early literature on the subject is a small work written in French by Monsieur le Compte d'Espie, Knight of the Military Order of St. Lewis, translated into English by L. Dutens, and published in London 1775, entitled "The Manner of Securing all sorts of Buildings from Fire, or A Treatise upon the Construction of Arches made with Bricks and Plaister, called Flat-Arches, and of a Roof without Timber, called a Bricked-Roof." The author writes: "The Invention is this; to erect a roof of such Construction (which three years ago I myself built on my House at Thoulouse) as to be absolutely composed of no other materials than Bricks, Mortar, and Plaister, there being no Wood or Iron in the whole Formation of it; and therefore I give it the Name of a *Bricked Roof*. . . . . It is much to be wished that they were universally introduced throughout the Kingdom, what a number of Lives as well as Houses would be preserved from Fire? Accidents that are now so frequent and so numerous would in a great measure be avoided, and besides this great Security, there are other advantages peculiar to these solid flat arches and ought to be well-weighed: for instance they make Apartments in Winter warm and in Summer cool, Rats and Mice can find no shelter there, neither is Noise anyways communicated from an upper to a lower Floor, which as the former now is, is very troublesome, notwithstanding the Care taken to fill up Vacancies and make our floors double, a Method very expensive and what is more takes up a great deal of Room; neither does it absolutely prevent the inconvenience, for an hollow disagreeable Sound is always perceptible, and besides the inclosed Timber of the Floor (as it lies out of Sight) in time grows rotten, no Repair therefore can be done, at last it falls and the whole must be rebuilt."

Another work also published in London in 1775 had for its title page "Various Methods to prevent Fires in Houses and Shipping, and for preserving the Lives of People at Fires with an Account of Remarkable Accidents by Fire, in different Parts of the World, selected historically, for the space of One Hundred and Eight Years, to this present Period: wherein The Negligence of Architects and Builders, in constructing Buildings in Town and Country is pointed out; and showing That the Encouragement of Arts and Sciences is a public Benefit to these Commercial Islands. With Abstracts from the last Act of Parliament, to regulate Buildings, and prevent Fires in London. Necessary to be known in all Families from the lowest Peasant to the highest Peer in the Realm. Approved by the Society of Arts, Manufactures and Commerce."

Compte d'Espie had taken his idea from the barrel vaults of the Romans, but his suggested elimination of iron in building has a comparative value in the light of subsequent experiments in fireproof construction in the United States from 1854 to 1870. During this period the substitution of iron for wood for all constructive purposes was thought an advance in the right direction, until it was discovered that iron of all kinds was unreliable if exposed to temperatures of 900° Fahr. and over. The danger to so-called fireproof buildings, in which only this incumbustible material had been extensively introduced, was much greater than to those which had been previously erected without any regard to protection from the effects of fire, in many instances, with structures in which cast-iron fronts had been exclusively used, the effect being a complete collapse. These failures helped to call attention to the danger of using *unprotected iron* for all purposes, and after 1870 the plan diminished in favor, there being an almost universal demand for the abandonment of constructive iron and a return to wood. Thoughtful investigators, however, had directed their attention to the necessity for protecting rather than discarding the use of iron for constructive purposes, and the advantages of *protected iron construction* began to be recognized. As soon as fire protection in connection with constructive steel became an accomplished fact, the improvement of both of these arts advanced rapidly, and the development of the capacity of steel for building purposes became no less remarkable than that of the fireproofing systems used in connection with the metal. The steel skeleton construction now in general use is the principal result, and newly introduced materials and processes are everywhere employed throughout the United States for all improved building purposes, their use also being extended to foreign countries.

The first valuable improvements in fireproofing cast-iron columns were made from 1875 to 1879 by Peter B. Wight, architect, who used porous terracotta in hand-made blocks. Soon after this, rolled iron I-beam girders were fireproofed with porous terracotta in many buildings. The first iron roof trusses of which the individual parts were covered with porous terracotta about 1878 are in the Board of Trade Building at Milwaukee. These were the beginnings of the protection of structural iron. Improvements in floor construction with a view to relieving the floors of weight were made before this time. The first use of hollow burned tiles for this purpose in the United States was made by the late George H. Johnson of Chicago. They were built in one of the corridors of the New York post office in 1873. About the same time Mr. Johnson — whose son, E. V. Johnson, was one of the founders of the Pioneer Fireproof Construction Company — used a similar floor construction in the Kendall building at Chicago, the Singer building at St. Louis, and several others. The contract for the fireproof work of the Chicago City Hall, awarded in 1879, was one of the first in which the fireproof protection of the columns and girders was combined with a floor construction of I-beams and flat hollow-tile arches. Almost all the improvements in the manufacture and use for fireproofing purposes of burned fireclay, between 1879 and 1885, were made by the experts of the Pioneer Fireproof Construction Company and the Wight Fireproofing Company. The Montauk, built in 1881–82, was the first high building erected exclusively for office purposes in Chicago, and is just within the limit of 130 feet now fixed by law, beyond which a building shall not go in Chicago. In it were combined all the plans and materials for fireproof construction then in greatest favor, and since the erection of that building all the improvements in the construction and fireproofing of high buildings have been made step by step. In 1884 the Mutual Life Building on Nassau street, New York City, was fireproofed throughout with porous terracotta and hollow fire-clays. This was the first building in which the under sides of the beams were ever covered by fireclay tiles for the protection of the same from fire, and leaving a flush ceiling.

The different materials now used in fireproof construction are few in number, and the peculiar application or use in certain places sometimes makes one more desirable than another. The following constitute the principal incombustible materials now in use, singly or in combination; dense and porous clay or terracotta; solid concrete as a lintel in floor construction; cinder concrete supported by light iron work; plaster block of plaster-of-paris and fire-clays as foundation material; expanded metal or wire lath supported on light iron work, leaving an air space. The different uses to which fireproofing material is put in a building are: for floors,— the filling in of the spans between iron beams; for partitions,— the 2-inch to 6-inch walls dividing the interior of a building into rooms; for furring — or covering the inside of exterior exposed walls, leaving an air space; for column covering — all interior columns, and those left exposed by brick work; for girder covering — all girders projecting below the floor arches; for ceilings — the placing of false or hanging ceilings; and for roofs — the flat or sloping base for slate, etc.

The standard regulations for fireproof buildings suggested by the National Board of Fire Underwriters, and incorporated in the building laws, provide that every building hereafter erected or altered to be used as a theatre, lodging house, school, jail, public station, hospital, asylum, institution for the use, care or treatment of persons, the height of which exceeds three stories, and not more than 40 feet in height, and every building hereafter erected or altered to be used as a hotel, which exceeds four stories, and not more than 50 feet in height, excepting all buildings for which specifications and plans have been heretofore approved by the proper authorities, and every other building, the height of which exceeds 55 feet or more than four stories in height, shall be built fireproof, that is to say — they shall be constructed with walls of brick, stone, Portland cement, concrete, iron or steel, in which wood beams or lintels shall not be placed, and in which the floors and roofs shall be constructed with rolled wrought iron or steel floor beams, so arranged as to spacing and length of beams that the load to be supported by them, together with the weights of the materials used in the construction of the said floors, shall not cause a greater deflection of the said beams than one-thirtieth of an inch per foot of span under the total load, and they shall be tied together at intervals of not more than eight times the depth of the beam with suitable tie-rods.

Between the floor beams shall be placed brick arches springing from the lower flanges of the steel beams, or the spaces between the beams may be filled with hollow tile arches of hard-burnt clay or porous terracotta, or arches of Portland cement reinforced with metal, or such other fireproof composition may be used, provided that in each and all cases the strength and method of construction shall be acceptable to the Inspector of Buildings. The stairs and staircase landings shall be entirely of brick, stone, Portland cement, concrete, iron or steel.

No woodwork or other inflammable material shall be used in any of the partitions, furrings or ceilings in any such fireproof buildings, excepting, however, that when the height of the building does not exceed eight stories, nor more than 100 feet, the doors and windows, and their frames and trims, the casings, the interior finish when filled solidly at the back with fireproofing material, and the floor boards and sleepers directly thereunder, may be of wood, but the space between the sleepers shall be solidly filled with fireproofing materials and extend up to the floor boards. When the height of a fireproof building exceeds eight stories or more than 100 feet, the floor surfaces shall be of stone, cement, rock asphalt, tiling or similar incombustible material, or the sleepers and floor boards may be of wood treated by some process approved by the Inspector of Buildings to render the same fire-retarding. All hall partitions or permanent partitions between rooms in fireproof buildings shall be built of fireproof material, and shall not be started on wood sills, nor on wood boards, but be built upon the fireproof construction of the floor and extend to the fireproof beam filling above. The tops of all doors and window openings in such partitions shall be 12 inches below. The provisions for inclosing structural iron and steel work, for elevator inclosures, stairs, openings in floors and roofs for light, ducts for pipes and ventilation, fireproof shutters and doors, the installation of electrical work and fire appliances are also outlined on a careful and elaborate scale, with which, however, great simplicity and perfection of construction are combined.

It has been pointed out that modern so-called fireproof appliances tend toward a protection of property rather than a protection for life, and the delusion of the "absolutely fireproof" building has provided a fertile theme for discussion, but it undoubtedly stands to reason that with the advances made in the fireproof construction of buildings, the danger to life has been, if not proportionately, at least considerably diminished.

The unsatisfactory nature of so-called "fireproof wood" has already been pointed out, and a movement for relief from compulsion in its use has long been agitated by architects and builders. Described as "an obnoxious imposition," a repeal of the fireproof wood clause in the Building Code is sought, and is now supported by the National Board of Underwriters. The influence of this clause has been much more detrimental than would appear to the casual observer. The permanence of any process or measure adopted for use in the great building industry, which architects, owners, and builders are all constantly studying to improve depends on merit alone. As such merit is established, no laws are required to secure prompt adoption.

Fireproofed wood is not a material of standard and recognized merit like hollow brick or wire glass. It is a material which has been for the most part manufactured in order to enable builders to meet the provisions of the law, and builders themselves have no confidence in the value of such fireproofing. Experts are agreed that the amount of wood used in the finish of buildings, the walls, floors, and windows of which are thoroughly fireproofed, is not a source of danger, and in building a skyscraper there is no ordinary business inducement to have the roof fireproofed. Fire Chief Croker of New York says "the only way to make a building fireproof is to build it of non-inflammable materials from the foundation up to the skylight, and permit only fireproof furniture to go in. And the less oil and paint used in a building which is desired to be fireproof, the better."

Among the leading systems of fireproof construction are the Roebling system, described as "a system of fireproof construction that is fireproof;" the Rapp system of fireproof construction; the Hennebique iron-concrete system of construction; the De Mann system of fireproof construction, the systems employed by the G. A. Fuller Construction Company and other building companies.

Of the many high buildings of steel skeleton construction erected in the large cities of the United States by the G. A. Fuller Company, in which the various problems of fireproofing were elaborately carried out, several passed through such disastrous ordeals as the Baltimore fire in 1904, and the earthquakes and fires of San Francisco in 1906. In no case was there any but trifling damage done to their structural portion. They were all repaired by renewing the woodwork and decorative portions of the buildings and the damaged part of the exteriors. The percentage of salvage in these buildings ranged from 60 to 85 per cent.

PAUL STARRETT,
President, Fuller Construction Company.

Fires, Notable. Among the more important and disastrous conflagrations of history were the following:

64. Rome burned for eight days; most of city destroyed.
1086. London; great part of the city destroyed.
1212. London; great part of the city destroyed.
1666. London; Great Fire, 2–6 September; 436 acres; loss, $50,000,000.
1794. London; 650 houses burnt; loss, $5,000,000.
1812. Moscow fired, 14–20 September; loss, $150,000,000.
1835. New York, 16 December; loss, $15,000,000.
1842. Hamburg, 5–7 May; loss, $35,000,000.
1845. New York, 20 July; loss, $7,500,000.
1861. London, Tooley Street, 22 June–22 July; loss $10,000,000.
1871. Paris, Communist outrages in May; loss $150,000,000.
1871. Chicago, 8–10 October; 2,124 acres; loss, $200,000,000.
1872. Boston, 9–10 November; loss, $75,000,000.
1903. Chicago, 30 December, Iroquois Theatre; 531 lives lost.
1904. Baltimore, Md., 7 February; loss, $70,000,000.
1904. New York, steamer General Slocum, June, nearly 1,000 lives lost.
1906. San Francisco, Cal., 18–21 April; earthquake and fire; loss about $300,000,000.

Firing Machines, blasting batteries, electric blasting machines or exploders are electric generators which are used in firing charges of explosives, in blasting, and in military and naval operations. Broadly speaking, there are three types: (1) in which the current is induced in coils of wire surrounding the poles of a permanent magnet, by suddenly detaching a soft-iron armature therefrom; (2) in which a coil-wound armature is rotated between the poles of a permanent magnet; (3) in which a coil-wound armature is rotated between the poles of an electro-magnet as in an ordinary dynamo. It has been found advantageous in practice to construct the dynamo-electric machines on the series method of winding, that is, the field-magnet coils, armature, and external circuit (which in this case is the firing-line) are joined together in series. These machines are operated by cranks or by means of racks and pinions, many mechanical arrangements having been devised by which to secure the continuously accelerated motion and automatic switch-off which is desired. The general principle upon which the dynamo-electric machines work is that an armature, rotated between the poles of an electromagnet, has set up in its coils a feeble electric current, due to the magnetization produced by the residual magnetism in the iron. By continuing rotation (with the firing-line short-circuited) the weak current thus started passes round the field-magnet coils, increases the intensity of the field, and, consequently, the volume of current in the armature. This gradual increase or building up of the current goes on, until the maximum capacity of the machine is reached. At the limit of magnetic saturation, the short circuit previously existing is automatically broken and the whole available energy is switched on to the firing-line, through the binding posts or terminals on the side or top of the machine, to which the leading wires are attached. Machines are rated in the market at the full number of detonators which a machine of that pattern will fire, but, to ensure freedom from "miss-fires," a machine should never be worked up to its rated maximum capacity. The diameters of the leading wires should vary with their lengths, thus for distance up to 600 feet No. 16 B. W. G. (0.065 inch) wire should be used, for 800 feet No. 14 (0.083 inch) and for 1,000 feet No. 13 (0.095 inch). To prevent accidental explosions, it should be the invariable rule, that the leading wires are not attached to the binding posts of a firing machine, until all other preparations for firing are completed and everyone has got to a safe distance from the blast or mine; and it should be also the invariable rule that the leading wires are detached from the machine as soon as the blast has been fired.

Firishtah, fē-rēsh'tä, more properly **Mohammed Kasim,** Persian historian: b. Astrabad about 1550; d. about 1612. He went to India, and was for some time the tutor of a native prince. He wrote a 'History of the Mohammedan Power in India till the Year 1612,' which is the best yet written on the period which it embraces.

Firmament, in ancient astronomy, the eighth heaven or sphere, with respect to the seven spheres of the planets which it surrounds. It is supposed to have two motions, a diurnal motion, given to it by the *primum mobile* from east to west, about the poles of the equator; and another opposite motion, from west to east, which last it finishes, according to Tycho, in 25,412 years; according to Ptolemy, in 36,000; and according to Copernicus, in 25,800; in which time the fixed stars return to the same points in which they were at the beginning.

Firman, fėr'man or fėr-män', in Turkey, any decree issued by the Porte and authenticated by the sultan's own cipher or signet. Each of the ministers and members of the divan has right of signing firmans relative to the business of his own department, but only the grand vizier is authorized to place at their head the cipher containing the interlaced letters of the sultan's name, which alone gives them force. A decree signed by the sultan's own hand is called hatti-sherif. The name firman is also applied to a passport issued either by the Porte or a pasha, enjoining the subordinate authorities to grant protection and assistance to the traveler in whose favor it is granted. (See TURKEY.) In India, a written permission to trade is called a firman.

Firozpur, fē-rōz-poor', India, town, Punjab, on the Sutlej River, three and a half miles from Sutlej, capital of a district of the same name. It has the largest arsenal in the Punjab. It has a trade in grain and manufactures of cotton. Pop., including the military cantonments two miles south of the city, 50,437. Firozpur is also the name of a town in Gurgaon district, Punjab. Pop. 6,848.

First Aid, the term applied to a plan for popularizing certain measures for the relief of the injured and distressed. Instant application is necessary in many cases, if remedial measures are to succeed. Thus a slight knowledge of the course of arteries and of means for compressing them will enable one to stay a fatal flow of blood. Antidotes for poison rapidly lose value as time elapses. The resuscitation of the drowning is largely a matter of persistence in artificial respiration. General knowledge of the cleansing of wounds is all-important. This knowledge is now widely used in armies and among people most liable to witness accidents, as trainmen, etc., circulars of instruction and packets containing the most necessary articles for dressing wounds being often furnished by those in authority.

First-born (Heb. *bekor,* Gr. *prōtotokos,* Lat. *primogenitus*), in scriptural use, signifies the first male offspring, whether of man or of other animals, due to the Creator by the Mosaic law as a recognition of his supreme dominion. The first-born male, whether of men or of animals, was devoted from the time of birth to God, and the first-born male child had to be redeemed one month after birth by an offering not exceeding in value five shekels of silver (Exod. xiii. 13), provided the child lived longer than that period. The first-born male of animals also, whether clean or unclean, was equally regarded as devoted to God. By the Mosaic law primogeniture had certain privileges attached to it, the chief of which were the headship of the family and a double portion of the inheritance. Among other nations considerable variety existed as to the succession of children to the inheritance of their parent. See INHERITANCE; PRIMOGENITURE.

First-footing, a Scottish practice still existing in Edinburgh, and elsewhere. Late in the evening of 31 December in each year, 2,000 or 3,000 of the common people assemble in the vicinity of the Edinburgh Tron Church, to ascertain on good evidence when the new year commences. When the clock is about to strike 12 they cheer so loudly that the strokes are not heard. Instantly that it has finished, they depart for the purpose of first-footing; that is, each one tries to be the first person that year to cross the threshold of his friend's house and wish him the compliments of the season. On such occasions also not a few are accustomed to drink their friends' health at the manifest risk of their own.

First-fruits and **Firstlings** are terms of the Mosaic and Jewish law, denoting respectively those portions of the fruits of the earth and of the increase of live stock which were to be offered to the Lord (for First-fruits, see Exod. xxii. 29; Num. xviii. 12, etc.; for Firstlings, see Exod. xiii. 12; Num. xviii. 15, etc.). A custom which had its rise in the Roman Catholic Church as early as the 6th century was that men ordained to ecclesiastical offices made to the bishop who ordained them an offering of some portion of the first year's revenue of the office. In course of time the claim of the See of Rome to the whole of the first year's income of a bishopric or an abbey or other office or benefice was recognized and enforced. When in 1531 King Henry VIII. forbade the payment of this tax to the papal see by his subjects, the amount of the first-fruits annually forwarded from England to Rome was about £3,000. When Henry was made supreme head on earth of the Anglican Church, the tax of the first-fruits was still exacted, but the proceeds were turned into the royal treasury. Such was the disposition made of the first-fruits in England till in 1704 Queen Anne, for herself and successors, relinquished the income from first-fruits and other imposts on the profits of spiritual preferments and, under an act of the Parliament, formed this income into a fund for the relief of clergymen holding poor livings: this is "Queen Anne's Bounty." The official name of first-fruits is *Annates*, or *Annalia*, from *annus*, year: they are also called *primitiæ*, the Latin equivalent of first-fruits.

Firth, Charles Harding, English historian: b. Sheffield, England, 16 March 1857. He was educated at Clifton and Oxford and since 1883 has devoted his attention to literary work and teaching at Oxford, having been lecturer at Pembroke College there 1887–93. He has published: 'The Clarke Papers' (1891–1901); 'Scotland and the Commonwealth' (1895); 'Scotland and the Protectorate' (1899); 'Oliver Cromwell' (1900); 'Cromwell's Army' (1901); etc.

Firth, Mark, English steel manufacturer: b. Sheffield 1819; d. 28 Nov. 1880. In 1849 with his father and brother he established in Sheffield the great Norfolk steel works, whose specialty soon became the manufacture of steel ordnance. He was a munificent benefactor to his native town, his gifts including almshouses (1869), a public park (1875), and the Firth College (1879) in connection with university extension.

Fis'cal, from *fiscus*, the state treasury. (1) In most German states an officer who has charge of the state treasury. (2) In the German states, and in Scotland, the fiscal is also the public prosecutor in the criminal courts. This use of the name seems to arise from the ancient practice of punishing most violations of the criminal law by a fine.

Fiscal Lands, lands, among the Franks, set apart for the use of the sovereign, to support his dignity, and to give him the means of rewarding merit or valor.

Fischart, Johann, yō'hän fish'ärt, German satirist: b. Mainz between 1545 and 1550; d. Forbach about 1590. As a satirist he is the most unrestrained of his age, inexhaustible in droll, humorous, and witty thoughts, not seldom guilty of equivoque and obscenity, intimately acquainted with the follies of his age, and never at a loss whether to ridicule or lash them. He treats the German language with the greatest freedom, coining new words and turns of expression without any regard to analogy, and displaying in his most arbitrary formations, erudition and wit. In the broad comic and burlesque he is not to be surpassed, and even in his most satirical effusions there is an honesty and good nature always observable. His most celebrated works are a rifaccimento of the Gargantua of Rabelais, first printed in 1575; 'Das gluckhaft Schiff von Zürich' (The Lucky Ship of Zurich) (1576); 'Aller Praklik Grossmutter' (1572); 'Eulenspiegel Reimensweiss' (1572), and several others. We find in Fischart the first attempt at German hexameters.

Fischer, Emil, ā'mēl fish'er, German chemist: b. Euskirchen 1852. He was appointed professor extraordinary at the University of Munich 1852 and became professor of chemistry at Erlangen 1882, filling a similar chair at Würzburg 1885. He was appointed professor of organic chemistry at the University of Berlin 1892, receiving in that year the Nobel prize for chemical research. He has paid much attention to the chemical constitution of sugars, his principal work being 'Anleitung zur Darstellung organischer Präparate.'

Fischer, Johann Georg, yō'hän gā-ōrg' fish'er, German poet: b. Gross Süssen, Würtemberg, 25 Oct. 1816; d. 1897. His lyric poems are in eight volumes (1854–91). He excelled in popular songs and ballads; and in his love songs nobly idealized nature and passion. He wrote four dramas: 'Saul' (1862); 'Frederick II. of Hohenstaufen' (1863); 'Florian Geyer' (1866); 'Emperor Maximilian of Mexico' (1868). In 'From Bird Life' (1863) he notes the characteristic phenomena of the psychic life of animals with the acuteness of a naturalist and the sympathy of a poet.

Fischer, Kuno, koo'nō, German historian of philosophy: b. Sandewalde, Silesia, 23 July 1824; d. Heidelberg, 4 July 1907. He was interdicted from teaching philosophy at Heidelberg in 1853; but after filling professorships in Berlin and Jena, had the satisfaction of being called to the chair of philosophy at Heidelberg in 1872. His principal writings are: 'Diotima; The Idea of the Beautiful' (1849); 'Logic and Metaphysic, or the Doctrine of Science' (1852); 'History of Modern Philosophy' (1852–93, new ed. in 9 vols. 1897 et seq.), his greatest work, written in the form of brilliant monographs on Descartes, Kant, Fichte, Schelling, and other great philosophers down to Schopenhauer; 'Francis Bacon and His Successors' (1856); 'Lessing's Nathan the Wise' (1864); 'Spinoza's Life and Character' (1865); 'Origin and Evolution-Forms of Wit' (1871); 'Goethe Schriften' (1895–1900).

Fischer, Ludwig Hans, lood'vig hänts, Austrian painter: b. Salzburg 2 March 1848. After a course of art study he traveled extensively, settling finally in Vienna. Among his works are nine landscapes for the Museum of Natural History, Vienna, and etchings and engravings forming historical landscapes from Austria-Hungary. He is the author of ‹Die Technik der Aquarellmalerei.›

Fiscus. See FISCAL.

Fish, Hamilton, American diplomatist: b. New York 3 Aug. 1808; d. Garrison, N. Y., 7 Sept. 1893. He was graduated at Columbia College, and admitted to the bar in 1830. A Whig in politics, he was elected a congressman in 1842, and governor in 1848. In 1851 he was returned to the United States Senate, where he opposed the repeal of the Missouri Compromise and joined the Republican party on its formation. He was secretary of state under Grant 1869–77, signing, as one of the commissioners, the Washington Treaty of 1871, and carrying through the settlement of the «Alabama» question.

Fish, Nicholas, American military officer: b. New York 28 Aug. 1758; d. there 20 June 1833. He joined the Continental army, participated in the battles at Saratoga in 1777; led a corps of light infantry in the battle of Monmouth; and otherwise distinguished himself during the Revolutionary War. He was made adjutant-general of New York in 1786; supervisor of United States revenue in 1794, and president of the New York State Cincinnati Society in 1797.

Fish, Nicholas, American diplomatist: b. New York 19 Feb. 1848; d. there 16 Sept. 1902. He was educated at Columbia and the Harvard Law School, practised law in New York, became second secretary of legation in Berlin 1871, secretary in 1874, and in 1877–81 was *charge d'affaires* in Switzerland. From 1882 to 1886 he was United States minister to Belgium, and in 1887 entered the firm of Harriman & Company, bankers of New York. He was a son of Hamilton Fish (q.v.), the well-known secretary of state, and president of the New York chapter of the Society of the Cincinnati.

Fish. In the popular sense a fish is a cold-blooded, chordate or vertebrate animal, adapted for life in the water, breathing by means of gill-slits all its life, having its limbs, if present, developed as fins, never as fingers or toes. This definition excludes invertebrates as having no notochord and no backbone. It excludes the tunicates and enteropneustans as not fish-like in form when adult, and as being at all times without fins. It excludes the amphibians, because these develop, in the adult state, jointed limbs with toes, and most of them cease to breathe with gills or gill-slits. The fishes, as thus defined include all members of the groups known as the lancelets (*Leptocardii*), the lampreys (*Cyclostomi*), the sharks (*Elasmobranchii*), and the true fishes (*Teleostomi*), as also all of the varied series of extinct fish-like form. In technical writings the lancelets and the lampreys are usually excluded from the class *Pisces* or fishes, and many writers would still further limit the name of *Pisces* by the exclusion of sharks and skates, and also the chimæras (*Holocephali*). Still others exclude the *Dipneusta*, and the extinct *Placodermi* or *Ostracophori*, and *Arthrodira*. It is perhaps not necessary to regard *Pisces* or fishes as a technical term at all. In this case there is no violence in using the word fish as coextensive with the popular definition as given above. Taking this significance, we may recognize two classes of chordates (*Tunicata* and *Enteropneusta*) as lying below and to one side of the series of fishes, while this series is itself composed of nine classes or sub-classes unequal in size and in taxonomic value, *Leptocardii*, *Cyclostomi*, *Cyclia*, *Elasmobranchii*, *Ostracophori*, *Arthrodira*, *Crossopterygii*, *Dipneusta*, and *Actinopteri*. The first two groups differ widely from the others, and must in any scheme of classification be regarded as forming distinct classes. The last-named class or sub-class includes the great majority of recent fishes. The *Cycliæ*, *Ostracophori*, and *Arthrodira* are wholly extinct; the *Crossopterygii* and *Dipneusta* nearly so.

Taking the true fishes, or *Actinopteri*, as typical of the group, we see at once that these have the general structure of the higher vertebrates, but with less complexity of structure, with various adaptations that fit these animals for life in the water.

Form of the Body.— The body is in general boat-shaped, the head in the same axis, without neck in most cases, the shoulder-girdle being attached to the skull at the nape, and in the more specialized forms the pelvic girdle joined to the shoulder-girdle below. In this case the vertebral column might be held to consist of skull and tail only. The form is fitted for swift progress through the water. The body is longer than deep, and the greatest width is in front of the middle, leaving in most cases the compressed paddle-like tail to serve as the organ of locomotion. To all of these statements there are numerous exceptions. Most fishes depend on speed to secure their food or to escape from their enemies, but there are some which preserve themselves by lying prone on the bottom, by hiding in crevices of one sort or another, or which are defended from all attacks by pungent spines or by a bony coat of mail.

Exoskeleton of the Fish.— The surface of the fish is typically covered by an exoskeleton of overlapping scales. To this there are many exceptions. Some are naked, some covered with prickles, spines, or bony plates. The scales may be ganoid (enameled, like teeth), placoid (reduced to shagreen-like roughness), ctenoid (with a comb-edge), or cycloid (smooth, with concentric striæ), or they may be variously coalescent, forming bony plates. Historically the placoid scale precedes the ganoid scale. This is followed by the cycloid, and finally by the ctenoid type. Bony plates may be formed by the coalescence of scales of any type.

Fins of the Fish.— In most cases the motion of a fish is mainly produced by the lateral movement of the caudal or tail fin, the other fins exerting chiefly the function of direction. In the more primitive of existing fishes the different fins are composed of soft rays connected by membrane. The soft rays are finely jointed and usually branched, as distinguished from the spines, which are without branches or joints, and which are usually stiff and pungent. In the more specialized fishes spines are usually present, these occupying the front of the dorsal and

SPINY-FINNED FISHES (Chætodontidæ).

5. The Prince Fish (Chætodon diacanthus dux).
6. The Emperor Fish Chætodon imperator).

anal fins, the first ray of the ventral fin being also spinous.

The fins usually present are of two kinds — the paired fins and the vertical fins. The paired fins are represented on either side of the body, the anterior or uppermost pair, the pectoral fins, representing in the fish the arms or forelegs of the higher vertebrates, the lower or posterior pair (ventral or pelvic fins) representing the hinder legs. The vertical fins are on the median line of the body, the dorsal on the back, the caudal on the tail, and the anal on the lower side behind the body cavity. Each of these fins is subject to great variation.

The vertical fins, with their appendages, arise from the modification and specialization of a dorsal median fold of skin. This is found in embryos and in the lancelet and other forms of low organization. It is generally believed that the paired fins, with the bones which support them, have been derived from a lateral fold of skin, similarly modified, and still more specialized. As to this, the evidence is much less complete than in the case of the vertical fins.

At the base of each ray or group of rays in the vertical fins, supporting bones are developed. These bones, called interspinal bones, stand in some definite relation to the bones of the vertebral column, to which, however, they are not directly joined.

The pectoral fin is attached, by means of certain intermediate bones, to the shoulder-girdle. The ventral fin is similarly joined to a pelvis. The pelvis in all the lower fishes is detached from the rest of the skeleton and placed beneath the body cavity. In the more specialized modern forms the pelvis is moved forward, usually connected with the shoulder-girdle, but sometimes attached at the throat well in front of the latter. In accordance with the insertion of the pelvis, the ventral fins are said to be *abdominal* (free from the shoulder-girdle), *thoracic* (connected with the shoulder-girdle), or *jugular* (in front of the shoulder-girdle).

Muscular System of the Fish.— The movement of the fins is accomplished through the agency of muscles. These organs lie band-like along the sides of the body, forming the flesh of the fish. They are little specialized, and not as clearly differentiated as in the higher vertebrates. In the typical fishes there are several distinct systems of muscles, controlling the jaws, the gills, the eyes, and the different fins. The largest of these is the great lateral muscle, composed of flake-like segments, these corresponding in general in number to the numbers of vertebræ. In general, the muscles are white in color and tender in substance. In a few fishes muscular tissues are modified into electric organs.

19. Distance from snout to nape or occiput.

The skeleton of the fish is cartilaginous in the more primitive forms, bony in the more specialized types. In all cases the bones contain less of mineral matter than do the bones of the higher vertebrates.

Skeleton of the Fish.— In the process of development the vertebral column is built up on a soft, cartilaginous cord extending lengthwise of the body, called the notochord. This exists in all young fishes, and is more or less completely persistent through life in the more primitive types, as the lamprey or the sturgeon. This notochord is not the backbone, but it indicates where the backbone is to be. In the higher forms the vertebræ are developed around it, strung spool-fashion, as it were, until finally in most recent fishes the original chord is entirely obliterated.

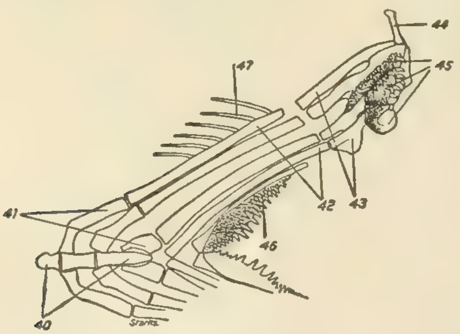
The skull of the fish consists of a great variety of bones, the names of which are given on the accompanying plate. In the naming of the bones of the head and shoulder-girdle of fishes great confusion has arisen. This is due mainly to ineffective attempts to trace the homologies of these bones with bones occupying similar positions in the skeleton of man; while, no doubt, the skeleton of the higher vertebrates is derived by descent from that of primitive fishes, homologies can be traced only in a general way. The skull of the one corresponds to the skull of the other, but the specialized fishes have developed many more bones than were found in ancestral types, and many more than exist in man. In like fashion the shoulder-girdle in the one represents that of the other, but the fish has more bones than can be covered by the names scapula, coracoid, and clavicle.



STRIPED BASS (*Roccus lineatus*). Branchial arches (after Starks).

41. Hypobranchials.
42. Ceratobranchials.
43. Epibranchials.
44. Suspensory pharyngeal.
45. Upper pharyngeal.

In the accompanying plate of the bones of the striped bass (after Edwin Chapin Starks) we use the terminology now adopted by Gill, Starks, and most American osteologists. The bones of the head may be roughly divided into those of the cranium, the jaws, the suspensory (of the lower jaw), the gill-structures, and the membrane-bones. The latter, on the outside of the head, are formed by ossification of the skin, and have no homologies among the higher vertebrates. They are also wanting in the sharks and lampreys.

The shoulder-girdle in the lower forms consists of an arch of cartilage. In the progress of specialization this is divided into several pieces as indicated in the plate. It is separate from the skulls in sharks and skates, as in the higher vertebrates. In the typical fishes its uppermost bone (post-temporal) is joined to the temporal bone of the cranium. In some groups it is immovably consolidated with the latter. In the eels, by a process of degeneration, it loses its connection with the skull. The pelvis in fishes usually consists of a single bone on either side, more or less fully coalesced with its fellow.

The vertebral column may be divided into abdominal and caudal vertebræ. The former have their lower processes divergent, to include the body cavity. In the caudal vertebræ, the hæmal processes unite, leaving opening only for the hæmal canal or place of the large artery. The neural processes of each vertebræ unite above the centrum or body of the vertebra, leaving space for the spinal cord. The pointed upper continuation of each is called the neural spine, as the downward projection is called the hæmal spine. In the primitive fishes generally the tail is extended to a point, the last vertebra being progressively reduced, and the caudal fin lying below the axis. This forms the heterocercal tail, characteristic of the shark, sturgeon, and of various extinct types of fish. In the modern types, the vertebræ cease more or less abruptly at the base of the caudal fin, the tail being homocercal.

The number of vertebræ is least in the more specialized, spiny-rayed fishes. In several families of these there are 24 vertebræ, 10 abdominal and 14 caudal. This number is much greater in all the soft-rayed and all the primitive forms. It is also materially increased by a process of degeneration in most arctic or subarctic derivatives from these families, and in general in fresh-water, pelagic, and deep-sea forms derived from forms having 24 vertebræ. In cold waters, fresh waters, and the oceanic abysses, the processes of competition called natural selection are apparently less active, and we have the phenomenon of reduction of parts with the increase in number of similar structures.

The cause for the vegetative increase in the numbers of vertebræ as we leave the tropical shores may perhaps be found in the reduction of the stress of natural selection. For such "cessation of selection" the name *panmixia* has been suggested by Dr. August Weismann. It should be noticed that the increase in the number of vertebræ is accompanied, necessarily, by the loss of importance and the reduction of specialization in each individual one. In this change the fin-rays usually share, there being a greater number, as a rule, in forms outside the tropics as compared with similar forms on warm shores.

Organs of Nutrition.— The organs of nutrition in the fish are generally homologous with those of higher vertebrates. Some fish feed exclusively on vegetable food. These have generally incisor-like teeth loosely planted in the gums, and a greatly elongate alimentary canal.

Most fishes feed on animal food, other fishes, crustaceans, mollusks, worms, insects, and whatever else may be found in the sea. The mouth and teeth are adapted to the kind of food, and the varieties in form and armature are even more varied than the forms of the body among fishes.

The mouth is usually capacious. It may have no teeth; it may have teeth on the jaws only, or any bone in its circumference may be armed with them. In most fishes additional teeth of one sort or another may be found on the pharyngeals, in the gullet behind the gills.

The stomach may be U-shaped — an opening at either end — or it may have the form of a blind sac, the two openings close together. Often glands, called pyloric cæca, secreting a digestive fluid, occur at the end of the stomach. The intestine may be a single tube, or it may be variously complicated, wound in spiral, or as in the sharks, having its surface increased by means of a spiral valve within. The liver, gall-bladder, and spleen are usually developed in fishes much as in the higher forms.

Fishes lack salivary glands. The tongue is cartilaginous or bony, with few nerves of taste, although taste buds may exist in the barbels, as in the cat-fish. Kidneys lie along the inner edge of the backbone, less specialized than in the higher vertebrates, their ducts leading into a common cloaca. In the lower fish-like forms (lancelets) the structures which serve the purpose of kidneys bear a close resemblance to similar glands (nephridia) in worms.

Organs of Respiration and Circulation.— In the lowest fish-like forms (lancelets), the heart is reduced to a simple pulsating tube. In the typical fishes it consists mainly of three parts, the auricle, the ventricle, and a thickened part of the large artery, known as the *bulbus arteriosus.* These parts correspond in a general way to right auricle and right ventricle in the higher vertebrates. The blood reaches the heart from the vein-system of the body. It is passed from auricle to ventricle, then sent through a large artery to the gills to be purified. From the gills it is distributed through the main artery or aorta to the different parts of the body, to be again gathered up from the capillaries into the veins.

It is not returned to the heart after purification, as in the higher vertebrates. Its flow is therefore relatively sluggish, and, as in reptiles and amphibians, its temperature is little above that of the environment. In some of the more primitive fishes the heart is more complex than in the typical forms, the arterial bulb being provided with a large number of valves.

All the chordate animals, including the tunicates and the *Enteropneusta,* have the purification of the blood effected through some form of gill-slit. In the lower forms these are merely slits, admitting water to the pharynx, where it comes in contact with thin membranes covering capillaries filled with blood.

In the typical fishes a much more elaborate apparatus is developed. There are usually five long bony arches attached to the cranium above and to the base of the tongue below. Each of these has two rows of slender filaments, the gills. The blood flows in and out of these filaments, where it comes in contact with the water. This water is swallowed through the mouth, and is forced out through the gill-opening. Behind the true gill-arches is a fifth arch, more or less similar, usually without gills, being modified to form a pair of gullet-jaws, the pharyngeals. On the anterior edge of the first gill-arch is a series of projections, sometimes forming a straining apparatus. These are the pharyngeals. A small accessory gill, the pseudobranchia, is usually developed on the inner side of the opercle or gill-cover.

In sharks and skates, the gills are fastened by their longer side, like the leaves of a book. In other groups there are many minor modifications.

In the sharks and skates there is no trace of lung or air-bladder. In the more primitive forms ancestral to the true fishes, there is a well-developed lung, which assists in the purification of the blood in exactly the same way as the lung of the higher vertebrates. Most of the forms known or supposed to possess lungs (*Dipneusta, Crossopterygii, Ganoideii*) are now extinct. In the few living forms with this character (*Neoceratodus, Lepidosiren, Protopterus, Polypterus, Lepisosteus,* and *Amia*) this lung is either of one or two lobes. It is connected by a trachea with the pharynx. In the earliest forms this windpipe opens below the œsophagus, as in the higher vertebrates, but in the other forms, the opening is transferred to the dorsal side. These early fishes were therefore literally amphibious, being capable both of breathing atmospheric air with the lungs, and the air dissolved in water, with the gills. There is little doubt that from some of these forms, probably crossopterygians, the whole series of land vertebrates is descended, while from the same stock has arisen the great body of the typical or bony fishes. In the former case we have the gradual obliteration of the gills, which are developed only in embryonic or larval stages. Among the typical fishes we have the gradual degeneration of the lung and the loss of its function as a breathing-organ.

In this case we have first the reduction of the lung to a single sac, the loss of its cellular structure. It assumes in the soft-rayed fishes the form of an empty sac, sometimes divided by a cross-constriction, the anterior part connected with the œsophagus by a very slender membranous tube. This tube is gradually lost in the spiny-rayed fishes, no trace of it usually existing except in the embryo. The airbladder is then a hollow sac, filled with air containing an excess of nitrogen, this air being secreted from the blood of the fish. The air-bladder has some value in enabling the fish to hold itself in place in the water. In pelagic fishes, and in fishes which habitually lie on the bottom, the air-bladder is often greatly reduced, or entirely obliterated, when the fish is fully developed. The different stages of the air-bladder must be looked on as steps toward the gradual loss of the lung, an organ which becomes progressively less important in the more complete adjustment of the fish to continuous life in the water.

The Organs of Sense.— The sense-organs of the fish correspond in general to those of the higher vertebrates. The sense of taste is, however, feeble, and that of hearing is muffled and without much power of acute discrimination. The sense of smell resides in the nostrils, which have no relation to the work of breathing. No fish breathes through its nostrils, and only in a few of the more generalized types does the nostril pierce through the roof of the mouth. In the bony fishes the nostrils are cavities, one on either side, lined with delicate or fringed membrane, well provided with blood-vessels, as with nerves from the olfactory lobe. In most cases each nasal cavity has two external openings, either simple or, with the rim of the nostril, forming a papilla or barbel. The openings may be round, slit-like, pore-like, or may have various other forms. In certain families of bony fishes there is but one opening to each nostril. In the sharks, rays, and chimæras there is also but one opening on either side, and the nostril is larger and highly specialized, with valvular flaps controlled by muscles which enable them "to scent actively as well as to smell passively."

In the lancelet there is a single median nostril, a small depression at the front of the body covered by ciliated membrane. In the hagfish the single median nostril pierces the roof of the mouth, and is strengthened by cartilaginous rings, like those of the windpipe. In the lamprey the single median nostril leads to a blind sac. In all other fishes there is a nasal sac on either side of the head. There is no doubt that the sense of smell in fishes is relatively acute, and that the odor of their prey attracts them to it. It is known that flesh, blood, or a decaying carcass will attract sharks, and other predatory fish are drawn in a similar manner. At the same time, the strength of this function is yet to be tested by experiments.

The Organs of Sight.— The eyes of fishes differ from those of the higher vertebrates mainly in the spherical form of the crystalline lens. This extreme convexity is necessary because the lens itself is not very much denser than the fluid in which the fishes live. The eyes vary much in size, and somewhat in form and position. They are larger in fishes living at a moderate depth than in shore-fishes or river-fishes. At great depths, as a mile or more, where all light is lost, they become aborted or rudimentary, and may be covered by the skin. Often species with very large eyes, making the most of a little light, or of light from their own luminous spots, will inhabit the same depths with fishes having very small eyes, or eyes useless for seeing, retained as vestigial structures through heredity. Fishes which live in caves become also blind, the structures showing every possible phase of degradation. The details of this gradual loss of eyes, either through reversed selection or hypothetically through inheritance of atrophy produced by disuse, have been given in a number of memoirs on the blind fishes of the caves of Kentucky, Missouri, and Cuba by Dr. Carl H. Eigenmann.

Many of the sharks possess a distinct nictitating membrane or special eyelid, moved by a set of muscles. The iris in most fishes surrounds a round pupil, without much power of contraction. It is frequently brightly colored, red, orange, black, blue, or green.

In the lowest of the fish-like forms, the lancelet, the eye is simply a minute speck coated by black pigment, connected with the spinal cord by a short nerve. In the development of such a pigment-spot the vertebrate eye doubtless has its origin. In the hagfishes, which stand next highest in the series, the eye, still incomplete, is very small and hidden by the skin and muscles. This condition is very different from that of the blind fishes of the higher groups, in which the eye is lost through atrophy, because in life in caves, or under rocks, the organ is no longer necessary.

The Ear of the Fish.— The ear of the typical fish consists of the labyrinth only, including the vestibule and three semi-circular canals, these dilating into one or more sacs which contain large, loose bones, the ear-stones or otoliths. There is no external ear, no tympanum, and no Eustachian tube. The ear-sac on each side is lodged in the skull or at the base of the cranial cavity. It is commonly surrounded by bone, but sometimes it lies near a fontanel or opening in the skull above.

The otoliths, two in each labyrinth, are usually large firm bones with enameled surface and peculiar grooves and markings. Each species has its peculiar type, but they vary much in different groups of fishes. The sense of hearing in fishes cannot be very acute, and is probably confined chiefly to the perception of disturbances in the water. Most movements of the fish are governed by sight rather than by sound.

Voices of Fishes.— Some fishes make distinct noises, variously described as quivering, grunting, grating, or singing. The name grunt is applied to species of *Hæmulon* and related genera, and fairly describes the sound these fishes make. The Spanish name *ronco* or *roncador* (grunter or snorer) is applied to several fishes, both sciænoid and hæmuloid. The noise made by these fishes may be produced by forcing air from part to part of the complex air-bladder, or it may be due to grating one on another of the large pharyngeals. The grating sounds arise, no doubt, from the pharyngeals, while the quivering or singing sounds arise in the air-bladder. The midshipman, *Porichthys notatus*, is often called singing-fish, from a peculiar sound it emits. These sounds may possibly be useful to the species, but they are not well differentiated, nor have they been so investigated as to be well understood.

Sense of Taste.— It is probably certain that fishes possess a sense of taste, though it is little differentiated, and is in some species located in the barbels about the mouth. The tongue is without delicate membranes or power of motion. In some fishes certain parts of the palate or pharyngeal region are well supplied with nerves, but no direct evidence exists that these have a function of discrimination among foods. Fishes swallow their food very rapidly, often whole; and mastication, when it takes place, is a crushing or cutting process, not one likely to be affected by the taste of the food.

Sense of Touch.— The sense of touch is better developed among fishes. Most of them flee from contact with actively moving objects. Many fishes use sensitive structures as a means of exploring the bottom, or of feeling their way to their food. The barbel or fleshy filament, wherever developed, is an organ of touch. In some fishes, as the moray, barbels are outgrowths from the nostrils. In the catfish the principal barbel grows from the rudimentary maxillary bone. In the horned dace and gudgeon the little barbel is attached to the maxillary. In other fishes barbels grow from the skin of the chin or snout. In the goat-fish and surmullet the two chin-barbels are highly specialized. In the cod-fish the single beard is little developed. In the gurnards and related forms, the lower rays of the pectoral are separate and barbel-like. Detached rays of this sort are found in the thread-fins, and in various other fishes. Barbels or fleshy flaps are often developed over the eyes, and sometimes on the scales or the fins.

The sense of pain is very feeble among fishes. A trout has been known to bite at its own eye, placed on a hook, and similar insensibility has been noted in the pike and other fishes. «The Greenland shark, when feeding on the carcass of a whale, allows itself to be repeatedly stabbed in the head when abandoning its prey.»

The Nervous System.— The nervous system in the fish, as in the higher vertebrates, consists of brain and spinal cord, with sensory or afferent and motor or efferent nerves. As in other vertebrates, the nerve-substance is divided into gray matter and white matter, or nerve-cells and nerve-fibres. In the fish, however, the whole nervous system is relatively small, its structures feeble, and the gray matter less developed than in the higher forms. According to Günther, the brain in the pike (*Esox*) forms but 1-1305th part of the weight of the body; in the burbot (*Lota*) about 1-720th part.

The cranium in fishes is relatively small, but the brain does not nearly fill its cavity, the space between the dura mater, which lines the skull cavity, and the arachnoid membrane, which envelops the brain, being filled with a soft fluid containing a quantity of fat.

It is most convenient to examine the fish-brain in its higher stages of development, as seen in the sun-fish, striped bass or perch. As seen from above, the brain of a typical fish seems to consist of five lobes or ganglia, four of them in pairs, the fifth posterior to these on the median line. The posterior lobe is the cerebellum or metencephalon, and it rests on the broadened termination of the spinal cord, called the medulla oblongata.

In front of the cerebellum lies the largest pair of lobes, each of them hollow, the optic nerves being attached to the lower surface. These are known as the optic lobes or mesencephalon. In front of these lie the two lobes of the cerebrum, also called the hemispheres, the prosencephalon. These lobes are usually smaller than the optic lobes and solid. In some fishes they are covered by a fold, but are never corrugated, as is the brain of the higher animals. In front of the cerebrum lie the two small olfactory lobes, which receive the large olfactory nerves from the nostrils.

In the hollow of the optic lobe are small protuberances, supposed to represent the corpora quadrigemina of the higher vertebrates. From its lower surface is suspended the hypophysis or pituitary gland.

In most of the bony fishes the structure of the brain does not differ materially from that seen in the perch. In the sturgeon, however, the parts are more widely separated, so that the connecting nerve-substance is more clearly seen between the several parts. In the dipnoans the cerebral hemispheres are united, while the optic lobe and cerebellum are very small. In the sharks and rays the large cerebral hemispheres are usually coalescent into one, and the olfactory nerves dilate into large ganglia below the nostrils. The optic lobes are smaller than the hemispheres and also coalescent. The cerebellum is very large, and the surface of the medulla oblongata is more or less modified or specialized.

Besides the structures noted in other fishes, the epiphysis or pineal organ is largely developed in sharks, and traces of it are found in most or all of the higher vertebrates. In some of the lizards this epiphysis is largely developed, bearin at its tip a rudimentary eye. This leaves no doubt that in these forms it has an optic function. For this reason the structure, wherever found, has been regarded as a rudimentary eye, and the «pineal eye» has been called the «unpaired median eye of chordate» animals.

It has been supposed that this eye, once possessed by all vetrebrate forms, has been gradually lost with the better development of the paired eyes, being best preservd in reptiles as «an outcome of the life-habit which concealed the animal in sand or mud and allowed the forehead surface alone to protrude, the median eye thus preserving its ancestral value in enabling the animal to look directly upward and backward.» In none of the fishes is the epiphysis more than a nervous enlargement, and neither in fishes nor in amphibia is there the slightest suggestion of its connection with vision. It seems probable, as suggested by Dr. Hertwig, that the original function of the pineal body was a nervous one, and that its connection with, or development into, a median eye in lizards was a modification of a secondary character.

The brain of the cyclostomes (hagfishes and lampreys) differs widely from that of the higher fishes, and the homologies of the different parts are still uncertain. The different ganglia are all solid and are placed in pairs. It is thought that the cerebellum is wanting in these fishes, or represented by a narrow commissure (*corpus restiforme*) across the front of the medulla. In the lancelet there is no trace of brain, the band-like spinal cord tapering toward either end.

The spinal cord extends from the brain to the tail, passing through the neural arches of the different vertebræ when these are developed. In the higher fishes it is cylindrical and inelastic. In a few fishes (head-fish, trunk-fish) in which the posterior part of the body is shortened or degenerate, the spinal cord is much shortened, and replaced behind by a structure called cauda equina. In the head-fish it has shrunk into "a short and conical appendage to the brain." In the cyclostomes and chimæras the spinal cord is elastic, and more or less flattened or band-like, at least posteriorly.

The nerves of the fish correspond in place and function with those of the higher animals. They are, however, fewer in number, both large nerve-trunks and smaller nerves being less developed than in higher forms. The olfactory nerves and optic nerves may be regarded as outgrowths of the brain. The olfactory nerves, or first pair, extend through the ethmoid bone to the nasal cavity, which is typically a blind sac, with two roundish openings, but is subject to many variations. The optic nerves, or second pair, extend from the eye to the base of the optic lobes. In cyclostomes these nerves run from each eye to the lobe of its own side. In the bony fishes or *Teleostei* each runs from the eye to the lobe of the opposite side. In the sharks, rays, chimæras, and ganoids the two optic nerves are joined in a chiasma as in the higher vertebrates. The other nerves arising in the brain need not be mentioned in detail.

A sympathetic system coresponding to that found in the higher vertebrates is found in all the *Teleostei* or bony fishes, and in the body of sharks and rays when it is not extended to the head.

The operations of the nervous system in fishes are essentially those of the higher vertebrates, the instincts being relatively weak and the intellect or power of choice among competing responses to external stimulus being apparently wanting. All acts of the fish may be regarded as reflex, the results of external stimulus or of stimulus arising within the body of the fish. These actions in each species tend to run in grooves or to be repeated in a special way for each species. These ways constitute the habits of the fish.

Organs of Reproduction.— In most fishes the germ-cells are produced in large sacs (ovaries, testes) arranged symmetrically one on either side of the posterior part of the abdominal cavity. The sexes are generally but not always similar externally, and may be distinguished on dissection by the difference between the sperm-cells and the ova. The ovary with its eggs is more yellow in color and the contained cells appear granular. The testes are whitish or pinkish, their secretion milk-like and, to the naked eye, not granular.

In a very few cases both organs have been found in the same fish as in Serranus, but all fishes seem to be normally diœcious, the two sexes in different individuals. There are no external genital organs, but in some species a papilla or tube is developed at the end of the urogenital sinus. This may exist in the breeding season only, as in fresh-water lampreys, or it may persist through life, as in some gobies.

The great majority of fishes are oviparous, the egg-cells being fertilized after deposition. The eggs are laid in gravel or sand or other places suitable for the species, and the milt or sperm-cells of the male is discharged over or among them in the water. A very small quantity of the sperm-fluid may impregnate a large number of eggs. In a number of families the species are ovoviviparous, the eggs being hatched in the ovary or in a dilated part of the oviduct. In no case is a real uterus developed. In the case of viviparous fishes actual copulation takes place, and there is usually a modification of some organ to effect transfer of the sperm-cells. This may be the sword-shaped form of the anal fin in many top-minnows, the fin itself being placed in advance of its usual position.

It may be an alteration of the structure of part of the anal fin as in the surf-fishes (*Embiotocidæ*); or, as in the *Elasmobranchi,* large bony organs (claspers) may be developed from the ventral fins.

In some viviparous fishes, as the rock-fishes and rose-fishes, the young fishes are very minute at birth. In others, as the surf-fishes, they are relatively large and few in number. In the viviparous sharks, which constitute the majority of the species, the young are large at birth and prepared to take care of themselves.

The eggs of fishes vary much in size and form. In those sharks and rays which lay eggs the ova are deposited in a horny egg-case, in color and texture suggesting the kelp in which they are laid. The eggs of the bull-head sharks (*Heterodontus*) are spirally twisted, those of the cat-sharks (*Scyliorhinidæ*) quadrate, with long filaments at the angles. Those of rays are wheelbarrow-shaped, with four handles. One egg-case may sometimes contain several eggs, and develop several young. The eggs of lancelets are small, but those of hagfishes and lampreys are large, ovate, with fibres at each end, each with a triple hook at tip. The chimæras have also large egg-cases, oblong in form.

In the higher fishes the eggs are spherical, large or small according to the species, and varying in the firmness of their outer walls. All contain food-yolk from which the embryo in its earlier stages is fed. The eggs of the eel (*Anguilla*) are microscopic. According to Günther, 25,000 eggs have been counted in the herring, 155,000 in the lumpfish, 3,500,000 in the halibut, 7,635,200 in the sturgeon, and 9,344,000 in the cod. Smaller numbers are found in species with large ova. Where an oviduct is present, the eggs are often poured out in glutinous masses, as in the bass. When, as in the salmon, there is no oviduct, the eggs lie separate and do not cohere together. It is only with the latter class of fishes, those in which the eggs remain distinct, that artificial impregnation and hatching are practicable. In this regard, the value of the salmon and trout is pre-eminent. In some fishes the ovary of but one side is developed.

In most fishes the parents take no care of their eggs or young. In a catfish (*Bunocephalus*) the eggs adhere to the under surface of the females. In a kind of pipefish (*Solenostomus*) a large pouch for retention of the eggs is formed on the belly of the female. In the sea-horses and pipefishes a pouch is formed in the skin, usually underneath the tail of the males. Into this the eggs are thrust, and here the young fishes hatch out, remaining until large enough to take care of themselves.

In certain sea catfishes the male carries the eggs in his mouth, thus protecting them from the attacks of the female. In numerous cases the male constructs a rough nest, which he defends against all intruders, against the female as well as against outside enemies. The nest-building habit is especially developed in the sticklebacks (*Gasterosteidæ*), a group in which the male fish, though a pigmy in size, is very fierce in disposition. In a minnow of Europe (*Rhodeus amarus*) the female is said to deposit her eggs within the shells of river mussels.

In the relatively few cases in which the sexes are unlike, the male is usually the brighter in color and with more highly developed fins. Blue, red, black, and silvery white pigment are especially characteristic of the male, the olivaceous and mottled coloration of the female. Sometimes the male has a larger mouth, or better developed crests, barbels, or other appendages. In some species the pattern of coloration in the two sexes is essentially different.

In various species the male develops peculiar structures not found in the female, and often without any visible purpose. In the male chimæra, a peculiar cartilaginous hook, armed with teeth at the tip, is developed in the male only. In the skates or true rays (*Raja*) the pectoral fin has near its edge two rows of stout incurved spines. These the female lacks.

In the breeding season the male sometimes becomes much brighter by the accumulation of bright red or blue pigment, black or white pigment-cells. This is especially true in the minnows, darters, and other fresh-water species which spawn in the brooks of northern regions in the spring. In the minnows and suckers horny excrescences are also developed on head, body, or fins, to be lost after the deposition of the spawn.

In the salmon, especially those of the Pacific, the adult male becomes greatly distorted in the spawning season, the jaws and teeth being greatly elongated, and hooked or twisted so that the fish cannot shut its mouth. After the act of spawning, all the individuals of these species die, both male and female. The Atlantic salmon and the trout show also some elongation of the jaws, but not to the same extent, and in these species the individuals mostly survive the act of spawning.

In fishes generally the eggs are laid in the spring, to be hatched in warming water. Among the salmon, trout, and cod-fishes, a reverse condition obtains. The eggs are laid in fall or winter, being deposited in water which is growing colder, hatching when the temperature of 54° F. is passed. In those fishes which pair, the relation seems not to be permanent, nor is anything to be called affection recorded among them.

Embryology and Growth of Fishes.— The egg of the fish develops only after fertilization, the union of its nuclear substance with that of a sperm-cell from the male. When this process, known as amphimixis, takes place, the egg is ready to begin its segmentation. The eggs of all fishes contain more or less of food-yolk attached to the structures of the germ-cell proper and included with it in the same spherical mass. The presence of this food-yolk affects the manner of segmentation.

The process of cell-division or segmentation common among fishes need not be described in detail, as it is essentially that of the higher vertebrates. When the food-substance or yolk is consumed, and the little fish is able to shift for itself, it leaves the egg-envelopes and is said to be hatched.

The young fish usually differs from the adult chiefly in size and proportions. The eye is larger, the head larger, the fins are lower, the appendages less developed, and the body more slender in the young than in the adult. But to most of these distinctions there are numerous exceptions, and in some fishes there is a change so marked as to be fairly called a metamorphosis. In such case the young fish in its first condition is properly called a larva. The larva of the lamprey (*Petromyzon*) is nearly blind and toothless, with slender head, and was long supposed to belong to a different genus from the adult. The larva of sharks and rays and of some dipnoans are provided with bushy external gills, which disappear in the process of development. In most soft-rayed fishes the embryonic fringe, which precedes the development of the vertical fins, persists for a considerable time.

Hybridism is very rare among fishes in a state of nature. Two or three peculiar forms among the snappers (*Lutianus*) in Cuba seem fairly attributable to hybridism, the single specimen of each showing a remarkable mixture of characters belonging to two common species. Hybrids may be readily made in artificial impregnation among those fishes with which this process is practicable. Hybrids of the different salmon or trout usually share nearly equally the traits of the parent species.

The age of fishes is seldom measured by a definite period of years. Most of them grow as long as they live, and apparently live until they fall victims to some stronger species. It is reputed that carp and pike have lived for a century, but the evidence needs verification. Some fishes, as the salmon of the Pacific (*Oncorhynchus*) have a definite period of growth (usually four years) before spawning. After this act all the individuals die — so far as known — without exception.

Fishes differ greatly in tenacity of life. In general, fishes of the deep seas die at once if brought near the surface. This is due to the reduction of pressure. This forces the stomach out through the mouth and may burst the air-bladder and the large blood-vessels. Marine fishes usually die very soon after being drawn out from the sea. Some fresh-water fishes are very fragile, dying soon in the air, often with injured air-bladder or blood-vessels. They will die even sooner in foul water. Other fishes are extremely tenacious of life. The mud-minnow (*Umbra*) is sometimes plowed up in the half-dried mud of Wisconsin prairies. The related Alaska black-fish (*Dallia*) has been fed frozen to dogs, and has escaped alive from their stomachs after being thawed out. Many of the catfishes (*Ameiurus*) will live after lying half-dried in the dust for hours. The dipnoan (*Lepidosiren*) lives in a ball of half-dried mud during the dry season, and the fishes, mostly Asiatic, with accessory breathing organ, can long maintain themselves out of water.

Some fishes can readily resist starvation, while others succumb as readily as a bird or mammal. The limits of distribution of many fishes are marked by changes in temperature. Few marine fishes can endure any sudden or great change in this regard, although fresh-water fishes adapt themselves to the seasons. Those fishes which are tenacious of life and little sensitive to changes in climate and food are most successfully acclimatized or domesticated. The Chinese carp (*Cyprinus carpio*) and the Japanese goldfish (*Carassius auratus*) have been naturalized in almost all temperate and tropical river-basins. Within the limits of clear, cold waters, most of the salmon and trout are readily transplanted. But some of these, as the grayling, are very sensitive to the least change in conditions. Most of the catfish (*Siluridæ*) will thrive in almost any fresh waters except those which are very cold.

The eggs of many salmon placed on ice to retard their development have been successfully transported to great distances. The king salmon has been thus transferred from California to Australia. It has been found possible to stock rivers and lakes with desirable species, or to restock those in which the fish-supply has been partly destroyed, through the means of artificially impregnated eggs.

Fishes have little power to reproduce lost parts. Only the tips of fin-rays or filaments are thus restored after injury. Sometimes a fish in which the tail has been bitten off will survive the injury. The wound will heal, leaving the animal with a truncate body, fin-rays sometimes arising from the wounds.

Fishes as Food for Man.— Among all races of men fishes are freely eaten as food, either raw, as preferred by the Japanese and Hawaiians, or else as cooked, salted, dried, or otherwise preferred.

The flesh of most fishes is white, flaky, readily digestible, and with an agreeable flavor. Some, as the salmon, are charged with oil, which tends to give an orange hue known as salmon-color. Others have colorless oil which may be of various consistencies. Some have dark red flesh, which usually contains a heavy oil that becomes acrid when stale. Some fishes, as the sharks, have tough, coarse flesh. Some have flesh which is watery and coarse; some are watery and tasteless. Some, otherwise excellent, have the muscular area, which constitutes the chief edible part of the fish, filled with small bones.

The writer has tasted most of the noted food fishes of the northern hemisphere. First in the ranks as a food-fish (when properly cooked, for he is no judge of raw fish) he would place the eulachon or candlefish (*Thaleichthys pacificus*). This little smelt, about a foot long, ascends the Columbia River, Frazer River, and streams of Southern Alaska in the spring, in great numbers, for the purpose of spawning. Its flesh is white, very delicate, charged with a white and very agreeable oil, readily digested, and with a sort of fragrance peculiar to the species.

Next to this he is inclined to place the ayu (*Plecoglossus altivelis*), a sort of dwarf salmon, which runs in similar fashion in the rivers of Japan and Formosa. The ayu is about as large as the eulachon, and has similar flesh, but with little oil and no fragrance.

Very near the first among sea-fishes must come the pompano (*Trachinotus carolinus*) of the Gulf of Mexico, with firm, white, finely flavored flesh.

The red surmullet of Europe (*Mullus barbatus*) has been long famed for its delicate flesh, and may perhaps be placed next. Two related species in Polynesia, the *Pseudupeneus bifasciatus* and *Pseudupeneus porphyreus*, are scarcely inferior to it.

Side by side with these belongs the whitefish (*Coregonus clupeiformis*) of the Great Lakes. Its flesh, delicate, slightly gelatinous, moderately oily, is extremely agreeable. It has long been known among hunters that one can eat the flesh of this fish longer than any other without the feeling of cloying. The salmon cannot be placed in the front rank because, however, excellent, the stomach soon becomes tired of it.

The Spanish mackerel (*Scomberomorus maculatus*), with flesh at once rich and delicate; the great opah (*Lampris luna*), still richer and more delicate; the bluefish (*Pomatomus saltatrix*), similar, but a little coarser; and the kingfish (*Scomberomorus cavalla*) firm and well-flavored, represent the best of the fishes allied to the mackerel.

The shad (*Alosa sapidissima*), with its sweet, tender, finely oily flesh, stands also near the front among food-fishes, but it runs above all others in the matter of small bones. The weakfish (*Cynoscion regalis*) and numerous relatives rank first among those with tender, white, savorous flesh. Among the bass and perch-like fishes, common consent places near the first the striped bass (*Roccus lineatus*), the bass of Europe (*Dicentrarchus labrax*), the susuki of Japan (*Lateolabrax japonicus*), the red tai of Japan (*Pagrus major*), the sheepshead (*Archosargus probatocephalus*), the muttonfish or pargo criollo of Cuba (*Lutianus analis*), the European porgy (*Pagrus pagrus*), the uku (*Aprion virescens*) of Hawaii, the spadefish (*Chætodipterus faber*), and the black bass (*Micropterus dolomieu*).

The various kinds of trout have been made famous the world over. All are attractive in form and color; all are gamy; all have the most charming of scenic surroundings; and finally, all are excellent as food-fishes — not in the first rank, perhaps, but well above the second. Notable among these are the European charr (*Salvelinus alpinus*), the American speckled trout (*Salvelinus fontinalis*), the dolly varden (*Salvelinus malma*), and the oquassa trout (*Salvelinus oquassa*). Less attractive are the true trout, the brown trout or Forelle in Europe (*Salmo fario*); the rainbow trout (*Salmo irideus*), the steelhead trout (*Salmo gairdneri*), the tahoe trout (*Salmo henshawi*), and the cutthroat trout (*Salmo clarkii*) in America; and the yamabe (*Salmo perryi*) of Japan. Not least of all these is the grayling (*Thymallus*), of different species in the streams of northern regions.

All these are the choicest prizes of the angler, and they have few rivals in any part of the world. Other most excellent food-fishes are the eel (*Anguilla* species), the sole of Europe (*Solea solea*), the pike (*Esox lucius*), the muskallonge (*Esox masquinongy*), the sardine (*Sardinia pilchardus*), the atka-fish (*Pleurogrammus monopterygius*) of Bering Sea, the pescado blanco (*Chirostoma estor* and other species) of Lake Chapala in Mexico, the Hawaiian mullet (*Mugil cephalus*), the California pesce rey (*Atherinopsis californiensis*), the Channel catfish (*Ictalurus furcatus*), the turbot (*Psetta maxima*), the barracuda (*Sphyræna*), and the young of various sardines and herring known as whitebait. Of large fishes, probably the swordfish (*Xiphias gladius*), the halibut (*Hippoglos-*

sus hippoglossus), and the king-salmon or quinnat (*Oncorhynchus tschawytscha*) may be placed first. Those who feed on raw fish prefer, in general, the large parrot-fishes (as *Pseudoscarus jordani*) in Hawaii, or else the young of mullet and similar species.

In general, the economical value of any species depends not on its toothsomeness, but on its abundance and the ease with which it may be caught and preserved.

It is said that more individuals of the herring (*Clupea harengus* in the Atlantic; *Clupea pallasii* in the Pacific) exist than of any other species. The herring is a good food-fish, and wherever it runs it is freely caught. According to Björnson, wherever the schools of herring touch the coast of Norway, there a village springs up, and this is true in Scotland, Newfoundland, and from Killisnoo in Alaska to Otaru in Japan and to Strielok in Siberia. Goode estimates the herring product of the North Atlantic at 1,500,000,000 pounds annually. In 1881, Prof. Huxley used these words:

> It is said that 2,500,000,000, or thereabouts, of herrings are every year taken out of the North Sea and the Atlantic. Suppose we assume the number to be 3,000,000,000 so as to be quite safe. It is a large number, undoubtedly, but what does it come to? Not more than that of the herrings which may be contained in one shoal, if it covers half a dozen square miles, and shoals of much larger size are on record. It is safe to say that scattered through the North Sea and the Atlantic, at one and the same time, there must be scores of shoals, any one of which would go a long way toward supplying the whole of man's consumption of herrings.

The codfish (*Gadus callarias* in the Atlantic; *Gadus macrocephalus* in the Pacific) likewise swarms in all the northern seas, takes the hook readily, and is better food when salted and dried than it is when fresh.

Next in economic importance probably stands the mackerel of the Atlantic (*Scomber scombrus*), a rich oily fish which bears salting better than most.

Scarcely less important is the great king-salmon or quinnat (*Oncorhynchus tschawytscha*) and the blueback salmon or red salmon (*Oncorhynchus nerka*). The canned product of the latter in Alaska alone amounts to nearly $5,000,000 annually.

The salmon of the Atlantic (*Salmo salar*), the various species of sturgeon (*Acipenser*), the sardines (*Sardinia*), the halibut (*Hippoglossus*), are also food-fishes of great importance.

In the tropics no one species is represented by enormous numbers of individuals, as is the case in colder regions. On the other hand, the number of species regarded as food-fishes is much greater in any given part. In Havana about 350 different species are sold as food in the markets, and an equal number are found in Honolulu. Upward of 600 different species appear in the markets of Japan. In England, on the contrary, about 50 species make up the list of fishes commonly used as food. Yet the number of individual fishes is probably not greater about Japan or Hawaii than on a similar stretch of British coast.

Catching Fishes.— In general, fishes are caught in four ways, by baited hooks, by spears, by traps and by nets. Special local methods, such as the use of the tamed cormorant, in the catching of the ayu, by the Japanese fishers at Gifu, may be set aside for the moment, and all general methods of fishing come under one of these four classes.

Of these methods, the hook, the spear, the seine, the beam-trawl, the gill-net, the purse-net, the sweep-net, the trap, and the weir are most important. The use of the hook is again extremely varied. Sometimes for codfish long sunken lines, each baited with many hooks, are used. For pelagic fish a baited hook is drawn swiftly over the surface, with a "spoon" attached which looks like a living fish. In the rivers the line is attached to a pole, and when fish are caught for pleasure or for the joy of being in the woods, recreation rises to the dignity of angling. Angling may be accomplished with a hook baited with an earthworm, a grasshopper, or the larva of some insect. The angler of to-day, however, prefers the artificial fly, as being more workman-like and also more effective than bait-fishing.

With the multiplicity of apparatus for fishing, there is the greatest variety in the boats which may be used. The fishing fleet of any part of the world is a most interesting object, as are also the fishermen with their quaint garb, plain speech, and their strange songs and calls with the hauling-in of the net.

Evolution of Fishes.— When a fish dies its body is at once attacked by hundreds of creatures ranging from the one-celled protozoa and bacteria to individuals of its own species. Its flesh is devoured, the bones are scattered, the gelatinous substance in them decays, and the phosphate of lime is in time dissolved in the water. For this reason few fishes of the millions that die each year leave any trace for future preservation. At the most, a few teeth, a fin-spine, or a bone buried in the clay might remain intact or in such condition as to be recognized.

But now and then it happens that a dead fish may fall in more fortunate conditions. On a sea-bottom of fine clay the bones, or even the whole body, might be buried in such a way as to be sealed up and protected from total decomposition. The flesh would in any case disappear and leave no mark, or at the most a mere cast of its surface. But the hard parts might persist, and now and then they do persist, the lime unchanged or else silicified or subjected to some other form of chemical substitution. Only the scales, the teeth, the bones, the spines and the fin-rays can be preserved in the rocks of sea or lake bottom. In a few localities, as Fossil Station, near Green River, Wyo., Monte Bolca in Tuscany, and Mount Lebanon in Syria, and in lithographic slates in Germany, many skeletons of fishes have been found pressed flat in layers of very fine rock, their structures traced as delicately as if actually engraved on the smooth stone. Fragments preserved in ruder fashion abound in the clays and even the sandstones of the earliest geological ages. In most cases, however, fossil fishes are known from detached and scattered fragments, many of them, especially of the sharks, by the teeth alone. Fishes have occurred in all ages from the Lower Silurian or Ordovician to the present time, and no doubt the very first lived before the Silurian.

No one can say what the earliest fishes were like, nor do we know their real relation to the worms, their presumable ancestors, nor to the tunicates and other chordate forms, not fish-like, but still degenerate relatives of the primitive fish.

From analogy we may suppose that the first fishes which ever were, bore some resemblance to the lancelet, for that is a fish-like creature with every structure reduced to its lowest terms. But as the lancelet has no hard parts, no bones, nor teeth, nor scales, nor fins, no traces of its kind are found among the fossils. If the primitive fish was like it in important respects, all record of it has necessarily vanished from the earth.

The next group of living fishes, the cyclostomes, including the hagfishes and lampreys, fishes with skull and brain but without limbs or jaws, stands at a great distance above the lancelet in complexity of structure, and equally far from the true fishes in its primitive simplicity. In fact, the lamprey is farther from the true fish in structure than a perch is from an eagle. Yet for all that, it may be an offshoot from the primitive line of fish-descent. There is not much in the structure of the lamprey which may be preserved in the rocks and no trace of fossil lamprey is actually known to exist.

The oldest unquestioned fragments of fishes have been very lately made known by Charles D. Walcott, from rocks of the Trenton Period in the Ordovician or Lower Silurian. These are from Cañon City, Col. Among these is certainly a small ostracophore (*Asterapis desiderata*). With it are fragments of a vertebral column, thought doubtfully to belong to an extinct type of chimæras (*Dictyorhabdus*) and other fragments of bony plates, referred with some doubt to the crossopterygian genus *Eriptychius*. This renders certain the existence of ostracophores at this early period, and their association with chimæras and primitive sharks is also probable. These early remains were from shallow, muddy water, more favorable perhaps for ostracophores than for sharks.

The fish-remains next in age in America are from the Bloomfield sandstone in Pennsylvania, of the Onondaga Period in the Silurian; the earliest in Europe are found in the Ludlow shales, both of these being in or near the horizon of the Niagara rocks, in the Upper Silurian Age.

It is, however, certain that these Ordovician remains do not represent the beginning of fish-life. Doubtless sharks, ostracophores and arthrodires, with perhaps chimæras, crossopterygians, and dipnoans existed at a far earlier period, preceded by unarmed, limbless forms, without jaws, of which no trace whatever has been left.

Next appear more or less simultaneously, in the early or middle Silurian, fin-spines, thought to belong to primitive sharks, remains of acanthodean and other sharks, and with these numerous bony shields of the mailed ostracophores, and somewhat later those of the more highly specialized arthrodires. Later appear cestraciont sharks, chimæras, dipnoans, and crossopterygians.

In the Devonian Age the ostracophores increase in size and abundance, disappearing with the beginning of the Carboniferous. The arthrodires also increase greatly in variety and in size, reaching their culmination in the Devonian, but not disappearing entirely until well in the Carboniferous.

These two groups (often united by geologists under the older name placoderms, given by McCoy), together with sharks and chimæras, made up almost exclusively the rich fish-fauna of Devonian times. The sharks were chiefly acanthodian and cladoselachean (*Pleuropterygii*), so far as our records show. The supposedly most primitive known type, that of *Cladoselache*, appeared in the middle Devonian. The *Ichthyotomi* (*Pleuracanthus*), sometimes regarded as still more primitive, are not known before the Carboniferous. In any case it is clear that the records of early shark-life are still incomplete. Chimæroids abound in the Devonian, and with them a considerable variety of crossopterygians and dipnoans. The true fishes appear also in the Devonian, in the guise of ganoid ancestors and relatives of *Palæoniscum*, all these with diamond-shaped enameled scales. In the Devonian, too, we find the minute, lamprey-like forms, our ignorance of which is concealed under the name *Cycliæ*.

In the Carboniferous Age the sharks increase in number and variety, the ostracophores disappear, and the arthrodires follow them soon after, in the Permian. Other forms of dipnoans, crossopterygians, and some ganoids follow, giving the fauna a somewhat more modern aspect. The *Acanthodei* and *Ichthyotomi* pass away with the Permian, which follows the period of coal.

In the Triassic the earlier types of ganoids give place to forms approaching the gar-pike and sturgeon. The crossopterygians rapidly decline. The dipnoans are less varied and fewer in number, and notidanoid sharks make their first appearance. All the ancient types of shark meanwhile have passed away, the *Cestraciontes* being the only group continued from the Permian to the Triassic. Here are found the first true bony fishes, derived from ganoid stock, the allies and predecessors of the great group of herrings. These become more numerous in the Jura, and in this age appear other forms which give the fish-fauna of this period something of a modern appearance. In this age the sharks become divided into several groups, *Notidani*, cat-sharks, lamnoid sharks, angel-fishes, skates, and finally typical sharks, being well differentiated from each other. Chimæras are still numerous. The *Acanthodei* have passed away, as well as the mailed ostracophores and arthrodires. The dipnoans and crossopterygians are few. The early ganoids have given place to more modern types, still in great abundance and variety.

This condition continues into the Cretaceous Period. Here the rays and modern sharks increase in number. The ganoids hold their own, and other groups of soft-rayed fishes, as the smelts, the lantern-fishes, the pike, and the flying-fishes, join the group of herring-like forms which represent the modern bony fishes. In the Cretaceous appear the first spiny-rayed fishes, derived perhaps from pike-like forms, the ancestors of the living genus *Beryx*. From the berycoids spring the perch-like and mackerel-like forms so numerous in recent times.

In the Eocene great changes have taken place. The early families of bony fishes nearly all disappear. The herring, pike, smelt, salmon, flying-fish and berycoids remain, and a multitude of others seem to spring up to join them. Among these are the bowfins, the globe-fishes, the trigger-fishes, the catfishes, the eels, the butterfly-fishes, the porgies, the perch, the bass, the pipe-fishes, trumpet-fishes, the mackerels, and the John-dory, with the sculpins, the anglers, the flounders, the blennies, and the cods. That all these groups, generalized and specialized, arose at once is impossible, although all seem to date from Eocene times. Doubtless all of them had their origin in earlier times, and the simultaneous appearance is related to the fact of the thorough study of Eocene shales which have in numerous localities (Green River, London, Monte Bolca, Licata, Mount Lebanon) been especially favorable for the preservation of their forms. Practically fossil fishes have been studied only in a very few parts of the earth. Scotland, England, Germany, Italy, Switzerland, Syria, Ohio, and Wyoming have furnished the great bulk of all the fish-remains in existence. In some regions perhaps collections may be made which will give us a more just conception of the origin of the different groups of bony fishes. We can now only say with certainty that the modern families were largely existent in the Eocene, that they sprang from ganoid stock, found in the Trias and Jura, that several of them occurred in the Cretaceous also, that the berycoids were earliest of the spiny-rayed fishes, and forms allied to herring the earliest of soft-rayed forms. Few of the modern genera go back to the Eocene; many of them arose in the Miocene; and few species have come down to us from rocks older than the end of the Pliocene. The general modern type of the fish-faunas being determined in the later Cretaceous and the Miocene, the changes which bring us to recent times have largely concerned the abundance and variety of the individual species. From geological distribution we have arising the varied problems of geographical distribution, and the still more complex conditions on which depends the extinction of species and of types.

For much information on the fishing apparatus in use in America, the reader is referred to the reports of the Fisheries in the 10th census (1880), under the editorship of Dr. G. Brown Goode. In these reports Goode, Stearns, Earll, Gilbert, Bean, and the present writer have treated very fully of all economic relations of the American fishes. In an admirable work entitled 'American Fishes' Dr. Goode has fully discoursed of the food and game fishes of America, with especial reference to the habits and methods of capture of each. To these sources, and to many others of similar purport in other lands, the reader is referred for an account of the economic and the human side of fish and fisheries. See FISHES, GEOGRAPHICAL DISTRIBUTION OF; ICHTHYOLOGY.

DAVID STARR JORDAN,
President Leland Stanford, Jr., University.

Fish Commission, in the United States, a bureau of the Department of Commerce and Labor, created by Congress in 1870, headed by the commissioner of fish and fisheries, with an assistant commissioner. It collects statistics of fisheries in the country, investigates the life histories and food of fish, and conducts experiments.

Fish-crow, a small species of crow (*Corvus ossifragus*), with a violet-green head, of the Atlantic coast, where it limits its wanderings to the sea-coast and tidal rivers, finding its food mainly along the beaches. It is perhaps the most destructive robber of birds' nests in the country. A similar species inhabits Cuba.

Fish Culture, or **Pisciculture**, the artificial propagation, fertilization, breeding, rearing, training and protecting of fishes, particularly food-fish. The art or industry was known in the early ages in China, and later in Germany and Sweden. In 1350, a monk, Dom Pinchon, hatched fish eggs by an artificial process, but the honor of introducing the modern plan of propagation is generally conceded to Stephen L. Jacobi, a Prussian soldier of Westphalia, who, in 1763, devised the process now in use in Europe and the United States, of stripping the ova from the female fish and mixing them with milt taken from the male. Fifty years after Jacobi's discovery, Joseph Remy, a fisherman of the Vosges Mountains, made the further discoveries upon which the culture depends — that the impregnation of fish eggs differs from that of all other oviparous animals in taking place after the eggs have left the body of the creature, and can therefore be performed as well artificially as by the animals themselves.

The first government fish culture station was established in 1850 at Hüningen, Alsace, and the following year a similar institution was established on the Tay in Great Britain. The process was introduced in the United States in 1865, when Dr. Garlick of Cold Springs, N. H., imported salmon eggs from Canada to hatch in the waters of his trout ponds. The process was also introduced in other sections of the country. The United States Commission of Fish and Fisheries, established by Congress 9 Feb. 1871, embraced in the scope of its work "the propagation of useful food-fishes, including lobsters, oysters, and other shellfish, and their distribution to suitable waters."

Technically, the process now in use consists in taking the ripe eggs from the female fishes and the milt from the male, mixing them artificially, and leaving them until impregnation has been effected, after which the eggs separate of themselves, and are placed in water, washed and treated in different ways according to the species or variety of the fish. Those of the salmon are placed in a filter-box or trough, through which passes a stream of pure water, and left to hatch into "fry," which process takes from 35 to 70 days. The advantage of pisciculture consists in the saving of multitudes of eggs which would otherwise be lost, the protection of the young fish from the dangers incident to their exposed condition, and the transplantation of species and varieties to other localities, where they soon become naturalized.

The operation for obtaining the ova and milt consists simply in pressing the body of the fish from the head toward the tail, and in collecting the excluded particles in a common vessel; the contents are occasionally put in motion in order to prevent the growth of parasites upon the eggs, which are very sure to destroy them. A low temperature and even desiccation is not necessarily fatal, so that many kinds in a nearly mature state may be transported for considerable distances. It has been estimated that 1,000,000 trout may be raised in this way at a cost of less than $200. Fish readily adapt themselves to new localities. Pickerel were easily introduced into ponds in Berkshire County, Mass., and the great pike of the northern lakes have been transplanted to the Connecticut River. The salt water smelt lives contentedly in ponds at Jamaica, Mass., and the tantog has found a new home in Massachusetts Bay. The expense of fish culture is small and the labor slight. There have been numerous inventions to aid the fish culturist, among them McDonald's fish-hatching jar which keeps the eggs in motion and automatically separates the dead fish from the living.

The United States government has established large salmon-breeding establishments in California and in Maine. It operates 28 hatcheries in various localities, owns 4 railroad cars for transporting eggs and young fish, and a steamer, the Fishhawk, is under its supervision. The vessel is in reality a floating hatchery. Western waters have been stocked with eastern fish and exhausted streams have been restored with a new supply. In 1901 the government planted 1,164,336,754 eggs and fishes in United States waters. Of this number nearly one fifth were shad and one fourth whitefish.

Aquatic birds are known to be of more or less assistance to the government in the dissemination of fish spawn. Naturalists tell us that these birds frequently carry the eggs from river to river and from lake to lake, by having their feet covered with the eggs. In the course of their flight the birds come to an inland sheet of water, or small creek, where they dive in or wade into the water, and the eggs are washed from their feet. In this way the waters become populated with new species and propagation progresses.

Fish culture has been found exceedingly profitable, too, as a private business or industry. There are over 400 fish hatcheries in Europe, and more than one half of these are owned by individuals. The Trout Pond Association, at Cold Springs, N. H., which began business in 1866, added a black bass branch in 1868, and erected salmon-breeding works in 1879, which in the first year yielded 450,000 eggs.

Several of the States have organized independent State Fish Commissions for the express purpose of disseminating the «fry» of food-fish in public waters. This is true of New York, whose commission of five members is appointed by the governor. Its principal office is at 83 Fulton Street, New York. The commission has established five hatcheries for the propagation of the «fry» from the eggs of the female fish, as follows: The Adirondack, Saranac; Cold Springs, Long Island; in Franklin County; Old Forge in the Fulton chain; at Newton Corners, and in Chautauqua County.

Fish Davit, in ship-building, a spar or small crane projecting from the bow of a ship for the suspension of the tackle, called the fish fall, used in hauling up the arms of the anchor in getting it aboard. The fish davit is such a distance abaft the cat-head as the length of the anchor may require, and is used to lift the fluke of the anchor to the bill-board; a roller keeps the fluke from bruising the vessel's side.

Fish Duck, a merganser (q.v.).

Fish-fly, one of the aquatic neuropterous insects of the family *Sialidæ*, and especially of the genus *Chauliodes,* represented by the hellgrammite and other species whose crawling larvæ are useful as fish-bait. See CORYDALIS.

Fish as Food in America. The question of the importance of fish as an article of food is no longer an open question. Recent food investigations have proved that it not only forms an economical source of variety to the diet, but that, like many other food materials, it also supplies the elements necessary for the building and repairing of the body as well as for maintaining the bodily heat required for energy and muscular work. With its protein, fat, and carbohydrates, the importance of its position has long been established, although the value of these properties differ in the dietary scale with the various fish, ranging in fuel value per pound from 40 calories represented by oysters in shells; 45 calories, shell crawfish and salted herring; and 65 calories for clams in shell, to 1,005 calories for canned salmon; 1,155 calories, canned salt mackerel; and 1,530 calories, caviare, as compared with 2,455 calories, the average value of beef, veal, and mutton; 1,670 calories, corn meal, and 1,655 calories, wheat flour.

Although the study of fish as a food is a wide subject, the most important difference that one detects in comparing the present with the past is represented in the method of preservation. Thus, for example, the method of salting and drying fish as practiced in Scandinavia is of the most remote antiquity, and as the aboriginal races in the Far North found it unnecessary, because of climatic conditions, to do anything more than dry their fish, this may be regarded as one of the earliest methods of preserving food for future use. The method of smoking fish to prepare them for eating unquestionably came later. In either instance, however, it was necessary that the work of curing should be performed as near the fishing ground as possible so it was to meet this requirement that the early Norse or Basque fishermen of the 12th and 13th centuries, as well as the English, French, and Spanish fishing fleets of the 16th and 17th centuries established so many colonies in the vicinity of the waters on which they sailed to fish.

From the earliest days of the history of this industry there has always been a great demand for cured fish, not only because it can be kept for a long time but also for its high nutrient qualities. As we have progressed in our knowledge of food compositions, therefore, we have applied our newly attained scientific knowledge to the improvement of the old methods of conservation, and yet, viewing our present achievements in the light of what we know about the past, we are compelled to admit that our present achievements are nothing more than a refinement of the methods that were pursued by the more ignorant fishermen several centuries ago.

The first attempt at refrigerating fish was made by Enoch Piper of Maine, but all his experiments were made in the British provinces. They were finally so successful that his methods were adopted by all large dealers in fish along the American seaboard with the result that fish, when the catch is in excess of the demand, is never lost but is stored in refrigerators until it can be disposed of at a fair price.

The invention of canning fish was perfected in Scotland, and was imported to this country in 1843, when a cannery for lobsters and mackerel was established at Eastport, Me. Owing to unfavorable legislation the lobster canning branch of the industry was not financially successful, but mackerel and other fish were preserved in this manner with profit to the canners. The canning of salmon, now one of the most important industries along the Pacific coast, dates from the year 1864. The product of this branch of the fishery industry was so successful from the date of its inception that it continued to increase its output until 1890 and 1891, when overproduction compelled the various companies to form a combine to regulate the product. Next to salmon, the sardine and its substitutes hold a position in the front rank of American canned fish. This branch of the industry was inaugurated in 1875, and, since that time, has presented a strong competition to the imported sardine. The centre of the sardine industry is in Maine.

As the canning industry is of comparatively recent origin some idea of its remarkable growth may be obtained by a glance at the Twelfth Census, in which it may be seen that, in the year 1900, the total value of the fish canned in the United States was $14,639,127, of which salmon was valued at $9,287,162, and the value of the sardine product at $4,212,351; the total value of the smoked fish was placed at $986,000, while that of the salted product was fixed at $5,260,927, of which sum cod alone represented about 60 per cent. Thus it may be seen that the total value of the American preserved fish industry was reported to be nearly $21,000,000 per annum.

Great as the demand for preserved fish has become the demand for the more natural fresh fish has also shown a constant increase. To have met such requirements a comparatively few years ago would have been impossible, whereas the more expeditious methods of transportation now enjoyed make the solution of this problem a simple one. In the old days of slow transportation fish was not shipped long distances, owing to the fact that it spoiled so easily, while this article of food is now transported from every part of the United States and Canada, to meet in the main centres of the commerce, where it is redistributed and shipped away again upon the largest scale possible.

The ever-increasing demand for all kinds of fish is partly explained by the increase in the population, but as the quantity of fish consumed per capita is also growing larger every day the question of the ability of the supply to withstand the demand has become an important one. To this there can be but one answer: So far as the deep-sea fish are concerned their number is practically inexhaustible, while, in the case of lake or river fish, as well as the various kinds of shell-fish, conditions are different.

Take, for example, the fishing grounds of Newfoundland. Discovered by the Cabots, they gave such an abundance of fish during the 16th century that no less than 5,000 men were steadily employed there. For nearly 400 years these same fishing banks have been the source of supply for a vast army of fishermen, and, although every kind of invention has been resorted to to increase the catch there has been no appreciable diminution of the staple fish in these waters.

So far as the rivers and lakes are concerned, however, this is not the case. There are some fish, called "anadromous," which, like the salmon and the shad, return periodically to the fresh from the salt water. Born at the source of a river, they go down to the salt water for certain periods of their existence, but they always return to the place of their origin when under the influence of the instinct of reproduction. As fish are in their best edible condition at about the time when they are laying their eggs, men have conspired to catch them at this period, and as there is no time when they can be caught more easily, it would require nothing more than a series of nets cross-barring a river to catch practically every anadromous fish that ventured into the stream. A practical illustration of this may be found in the Columbia River. Once the finest salmon river in the world, it has now, from over-fishing, been almost depleted of its stock. So, too, the building of dams for manufacturing purposes in so many New England rivers has driven the anadromous fish to seek other spots to lay their eggs. To a certain extent the same thing is true, even in regard to the great American lakes. Vast as their extent may be they are still restricted areas of fresh water. As the result the range of fish is necessarily limited and if no effort were made to protect them, indiscriminate capture would inevitably lead to their complete destruction. It is wise and proper, therefore, that State Legislatures should pass laws restricting lake and river fishing to certain seasons and regulating the character of the nets to be used, the size of the meshes, etc.

The same principle not only holds good in regard to all kinds of shell-fish, but, especially so far as the oyster is concerned, the problem which is presented is a most serious one. The oyster-beds of Maryland and Virginia were at one time considered almost inexhaustible, but, as the demand for this bivalve has constantly increased, the almost ceaseless dredging for the oyster has shown that even such beds as those of Chesapeake Bay are unable to stand the demands made upon them. Fearful of the total extinction of the species, science has adopted every precaution to prevent such a possibility. Titles have been granted to oyster-beds, or privileges of dredging have been rented; the planting of oysters has been encouraged, and laws have been passed regulating the work of dredging. In spite of all these efforts, it is feared that the prolific day of the oyster has passed.

Clams, lobsters, and terrapin are among the other shell-fish that have shown the most serious effect of over-fishing. Clams are by no means as plentiful as they were a few years ago, and in some waters they have practically disappeared altogether, and while terrapin in the far South are still moderately abundant their over-capture has made them very scarce in more northern waters. For years lobsters have been steadily decreasing in number, a fact that is due not only to over-fishing but also in the indifference shown by their captors in regard to the age of the catch, and while legal restrictions were long ago placed upon the indiscriminate catching of this fish the difficulties found in enforcing the laws have prevented their successful operation.

It is not by legal enactment alone, however, that efforts have been made to increase the fish production of the country, for it is in this emergency that the new science of fish culture has exercised an important influence for good. While fish culture alone is unable to create fish the scientists have devoted themselves so closely to the spawning habits of the fish that they are now able to secure the fecundated eggs, to hatch them artificially, to rear the young fish, caring for them until they are old enough to supply their own wants, and then to introduce the young fry in large quantities in such rivers or lakes where, from over-fishing, or from some other known cause, such fish are scarce. It was many years ago that the attention of the Government was first called to this matter, and, in 1871, the demand for protective legislation became so great that the United States Fish Commission was established, with the late Spencer F. Baird at its head. It is only just, however, to state that the first practical efforts in the direction of sensible fish culture were made through the enterprise of a private body, the American Fish Culture Association, and it was largely due to the influence which they exerted that the Government consented to establish its bureau of fish culture. To-day, if never before, the wisdom of the introduction of scientific methods in the care and protection of fish is absolutely beyond question, for it is to the fish-culturist that we must look for our future supply of fresh water fish. It is that power that is engaged in planting the fingerling in our lakes and streams, that, in years to come, when the fish has had time to grow to full size, the American people may have the wholesome food that is in such great demand. Moreover, the question of the depletion of the shell-fish supply is also receiving attention from the scientists who are employed in this work, and while their efforts have not yet met with the success for which they may have hoped it is by no means impossible that they may yet devise some means of relieving the oyster and lobster situation.

According to the list of the fish sold in the New York market in 1804, it may be seen that, about a century ago, only 57 varieties were known, whereas, to-day, more than 75 different kinds of sea-products are offered for sale in the markets of any of the American seaboard cities, the number varying a little, of course, according to the season. It is chiefly during the past few years that the number of varieties has shown such marked increase, a circumstance which may be traced to the fact that improved railway facilities have made the transportation of this product from long distances thoroughly practicable. According to the census report for 1900 the total catch of the United States fishing industry was valued at $46,453,000, while the annual value of the oil and fertilizer derived from the menhaden fisheries was in excess of $2,500,000. See CANNING INDUSTRY.

Fish-hawk, or **Osprey.** This almost cosmopolitan bird is known throughout North America as the "fish-hawk," never in popular speech as "osprey." The species (*Pandion haliaëtus*) occurs on all continents, gathering in the neighborhood of the sea and other large bodies of water, where it dexterously procures the living fish that constitute its food, by plunging from a great height and seizing them in its talons. These gains it is frequently obliged to relinquish to the fish-loving sea-eagles, especially our own bald eagle, which pounces upon the osprey and forces it to drop its property to be caught and swallowed by the robber. Fish-hawks have increased rather than diminished in most of their American haunts where they are protected by law and good-nature, and for the picturesqueness they lend to the landscape. Their nests are huge masses of sticks, placed on a ledge of rocks, or along low shores, in trees, and reoccupied for a long series of years. On the New England coast fish-hawks often make nests in belfries or on platforms set up on stout poles for their accommodation. The eggs are dirty white, marked with irregular purplish and red-brown blotches. This fine hawk (*Pandion haliaëtus*) is about 25 inches long, and has long pointed wings giving it great power and grace in flight. The general color of the upper parts is brown, but the head, neck and all under parts are white, except a band of brown spots across the breast. It stands alone among falconiform birds in a family (*Pandionidæ*) equivalent in rank to the *Falconidæ*, from which it essentially differs in the reversibility of the outer toe; the toes are nearly equal, and have no connecting membrane, but with spicules on their under surfaces and much curved claws enabling the birds to take a firm hold of their slippery prey. A general guide to further information as to the osprey in the Old World may be found in Newton's 'Dictionary of Ornithology'; and as to the American fish-hawk in Dr. Fisher's 'Hawks and Owls of the United States.'

Fish-killer, one of the huge heteropterous bugs (q.v.) of the aquatic family *Belostomidæ*, some of which reach a length of four inches, and are able to overcome small fishes. They are oval in outline, dull brown in color, and possess powerful mouth-parts by which they first stab their prey, then seize it and suck its blood. Their legs are flattened, and form powerful paddles, but are also useful for walking; and, supplied by the bubbles of air they take down with them, these big bugs lurk on the muddy bottoms of sluggish waters, ready to rush at and capture their living food. They are highly destructive among the fry in piscicultural ponds, and should be carefully eradicated. They come out of the water in early summer and fly in swarms at night, gathering about lights: and in some places so throng the street-lamps that they have become known as "electric-light bugs." Consult Howard's 'Insect Book' (1901); and see FRESH-WATER INSECTS.

Fish-lice, any of many copepod crustaceans, mainly of the group *Siphonostoma*, parasitic on marine animals. All are of small size, often very unlike ordinary *Copepoda* (q.v.) in appearance, and usually transparent. They are born of eggs attached to stones, plants, and the like, and begin life as normal larvæ, but some become parasitic and retrograde: yet some species are able as adults to swim about and change their hosts. These copepods attach themselves to the host by the suckers at the mouth, or by a sucking proboscis, and in some cases, by hooks on the forward swimming-appendages. While generally they confine their attacks to the exterior of the host, some live in the gills of fishes, and others embed themselves in the muscles. *Argulus* is a temporary epizoön. With four pairs of swimming-feet, it moves freely, and is not confined to a single host, entering the gills of a fish, there living for a time, and then enjoying a free life until it is hungry, when it enters another host. *Caligus* is sessile, and attaches itself to the gills of a fish, on whose blood it lives permanently. *Lernea*, and related forms, are wormlike, and anchor in the gills or in the skin of all kinds of fishes, and are sometimes so numerous as finally to cause the death of the host. Not only fishes, but all sorts of marine animals, including whales, are infested by these parasites, which have been extensively studied and reported upon by the United States Fish Commission, whose publication should be consulted.

Fish of Paradise. See PARADISE FISH.

Fish Trap, a box or basket set in a river, and containing bait to attract fish. A basket, net, or staked area with a divergent-sided or funnel-shaped opening through which fish pass, and in which they find a difficulty in retracing their course, owing to obstacles or blind sacs.

Fish'er, Charles, American comedian: b. Suffolk, England, 1816; d. New York 1891. He made his first appearance at the Princess Theatre, London, in 1844, but from 1852 was identified with the American stage, on which he made his début as Ferment in 'The School of Reform.' From 1872 to 1890, when he retired, he was a member of Augustin Daly's company. Best known as Triplet in 'Masks and Faces,' he was also seen as Jacques in 'As You Like It,' and Sir Peter Teazle in 'The School for Scandal.'

Fisher, Clara, American actress: b. London, England, 14 July 1811; d. Metuchen, N. J., 12 Nov. 1898. She made her first appearance on the stage in London when six years old, as Lord Flimnap in 'Gulliver in Lilliput.' Her success at this early age was phenomenal. Later under the direction of her parents she made tours of the United Kingdom, and besides other parts played Norval and Sir Peter Teazle for five years with great financial success. She made her first appearance in the United States as Albina Mandeville in 'The Will' at the Old Park Theatre in New York in 1827. Her success was immediate. Later she visited all of the larger cities of the eastern, southern, and western States. In 1834 she married James Gaspard Maeder, a well-known musician, and settled in Albany, N. Y. She, however, continued on the stage till 1889, when she retired.

Fisher, Frederic Henry, English journalist: b. London, England, 13 April 1849. He has been editor of the 'Literary World' from 1883 and has published: 'Cyprus, Our New Colony, and What We Know About It' (1878); 'Afghanistan and the Central Asian Question.'

Fisher, George Jackson, American physician: b. Westchester County, N. Y., 27 Nov. 1825. He was graduated from the medical department of New York University in 1849; was physician and surgeon at Sing Sing State Prison 1853–4; surgeon to the 7th Brigade, National Guard, State of New York, in 1853–73; and president of the New York Medical Society in 1874. He published 'On Animal Substances Employed as Medicines by the Ancients' (1862); and many other professional monographs.

Fisher, George Park, American educator: b. Wrentham, Mass., 10 Aug. 1847; was graduated at Brown University in 1847; studied theology at the Yale Divinity School, at Andover, and in Germany, was professor of divinity 1854–61, and subsequently of ecclesiastical history at Yale. He is the author of: 'Essays on the Supernatural Origin of Christianity' (1865); 'History of the Reformation' (1873); 'The Beginnings of Christianity' (1877); 'Faith and Rationalism' (1879); 'The Christian Religion' (1882); 'The Grounds of Historic and Christian Belief' (1883); 'Manual of Christian Evidences' (1890); 'Colonial History of the United States' (1892), etc.

Fisher, Irving, American educator: b. Saugerties, N. Y., 27 Feb. 1867. He was graduated at Yale 1888 and took a post-graduate course in Berlin and Paris. He was made instructor in mathematics at Yale 1890, becoming assistant professor of mathematics 1893. He has been professor of political science there from 1895. He has published: 'Mathematical Investigations in the Theory of Value and Prices' (1892); 'Bibliographies of the Present Officers of Yale University' (1893); 'Elements of Geometry,' with A. W. Phillips (1896); 'A Brief Introduction to Infinitesimal Calculus' (1897).

Fisher, John, English prelate: b. Beverley, Yorkshire, 1459; d. London 22 June 1535. In 1501 he was made chancellor of the University of Cambridge, and in 1502 became the first Margaret professor of divinity at Cambridge. In 1504 he was promoted to the see of Rochester. Deeply prepossessed in favor of the ancient faith of the nation, he opposed with zeal and perseverance the principles of Luther and his followers. But the same conscientious motives which induced Fisher to become the champion of Henry VIII., impelled him to oppose the king's measures for procuring a divorce from his wife, and declaring himself head of the Church. In 1527 he was the only prelate who had the courage to refuse to sign a declaration that the marriage of the king was unlawful. He was subsequently sent to the Tower for refusing to submit to the provisions of an act of Parliament which annulled the king's marriage with Catharine of Aragon, and confirmed his subsequent union with Anne Boleyn. Pope Paul III. thought proper to reward his zealous adherent by giving him a cardinal's hat (May 1535). The king exclaimed in a passion, "Mother of God! he shall wear it on his shoulders, for I will leave him never a head to set it on." As no evidence against him existed sufficiently strong to affect his life, Henry employed crafty emissaries to entrap Fisher into a positive denial of the king's supremacy. The plot succeeded, and the bishop was beheaded on Tower Hill. Bishop Fisher was an able theologian, and the author of a commentary on the Seven Penitential Psalms, of sermons, controversial and devotional treatises, etc.; his writings being partly in Latin, partly in English.

Fisher, Joshua Francis, American author b. Philadelphia, Pa., 1807; d. 1873. He was graduated from Harvard in 1825, was admitted to the bar in 1829, practised in Philadelphia, and was there one of the incorporators of the Pennsylvania Institution for the Instruction of the Blind. His historical studies include: 'The Private Life and Domestic Habits of William Penn' (1836); and 'The Degradation of Our Representative System' (1863).

Fisher, Mary, American educator: b. Marshall County, Ill., 12 April 1858. She is a teacher of French and German in the Kansas City Manual Training High School, and has published: 'Twenty-five Letters on English Authors' (1895); 'A Group of French Critics' (1897); 'A General Survey of American Literature' (1899).

Fisher, Sydney George, American lawyer and historical writer: b. Philadelphia, Pa., 11 Sept. 1856. He was graduated at Trinity College 1879, studying law at Harvard, and being admitted to the bar 1883. His works include: 'The Evolution of the Constitution' (1887); 'The Making of Pennsylvania' (1896); 'Pennsylvania: Colony and Commonwealth' (1897); 'Men, Women, and Manners in Colonial Times' (1898); 'The True Benjamin Franklin' (1899); 'The True William Penn' (1900); 'The True Story of the Revolutionary War' (1902).

Fisher, William Arms, American musician and composer: b. San Francisco, Cal., 27 April 1861. He was a pupil in counterpoint, canon, and fugue of H. W. Parker, in composition of Dvorák, and in singing of William Shakespeare. In 1897 he became an editor for Oliver Ditson & Company, the Boston music-publishers. His compositions number an 'Elegie' for violin and piano, some 40 solo songs, and many part-songs and anthems.

Fisher. Pennant's marten. See MARTEN.

Fisheries, a term which includes the taking of all kinds of water products as a business, and thus applies to the pursuit of whales, seals, otters, and other mammals; to the hunting of frogs, turtles, and alligators; to the taking of oysters, clams, lobsters, crabs, shrimp, and other shellfish; and to the gathering of corals, sponges, and seaweeds, as well as to the capture of fish proper. Closely related to the fisheries are fish culture, by which the supply of water animals is maintained and increased; and the various shore industries having for their object the utilization or preservation of the products as brought in by the fishermen.

The countries whose fisheries are of greatest commercial importance, being worth upward of $5,000,000 yearly, are the United States, Great Britain, Japan, Russia, France, Canada, Norway, and Newfoundland, in about the order given. Countries which may be regarded as of second-rate importance in this respect, whose fisheries are worth between $1,000,000 and $5,000,000 annually, are Portugal, Spain, Holland, Sweden, Germany and Italy. No data are available for China and India, whose fisheries must be very extensive, and perhaps entitled to rank with those of the leading countries. An estimate based on official data and all other available information gives $300,000,000 as the approximate annual value of the commercial fisheries of the world. Water animals which are of great economic importance in both hemispheres are whales, seals, sea-herring, mackerel, tunny, cod, halibut, lobsters, shrimp, oysters, and sponges. The most valuable of all fishery products are oysters; the most valuable of all fishes are sea-herring, salmon, and cod.

United States.— This is the leading country as regards the aggregate value of its fisheries and the amount of capital invested in the fishing in-

Rank	States	Persons employed	States	Capital invested	States	Value of products
1	Maryland	36,260	Massachusetts	$13,372,902	Alaska	$7,412,456
2	Virginia	29,325	New York	9,865,759	New Jersey	4,755,522
3	Maine	16,954	Washington	6,601,243	Virginia	4,613,384

dustry, and it also takes first rank in the yield of a number of special products common to many countries. The importance attained by the United States fisheries has been due to the abundance, variety, excellence, and wide distribution of the products, augmented by cultivation and acclimatization. The abundance of food fishes had a marked influence on the original colonization of the country, and was also an important factor in the subsequent development of various regions. At the outbreak of the Revolutionary War, some of the vessel fisheries had already become very extensive, and sailor-fishermen, mostly from New England, manned our naval vessels and privateers and rendered valiant service.

The number of persons who are regularly engaged in the fishing industry (1903) is about 212,000, of whom 154,000 are sea fishermen and 58,000 shoresmen, preparators, factory hands, etc. The aggregate number of people dependent on the fisheries is upward of 1,000,000, or about one eightieth of the entire population. The capital invested in the fisheries is about $76,720,850, of which $13,456,050 represents vessels, $4,530,600 boats, $8,215,330 apparatus and appliances, and $50,518,835 shore property and cash capital. The number of fishing vessels is 6,337, tonnage 172,377, and the number of open boats and vessels under five tons' burden is 79,216. The yield of the United States fisheries fluctuates considerably, but of late has averaged about $45,000,000. The statistics herewith presented, which embody the latest returns for the different regions, give a total catch of $49,696,900, a sum representing the value of the fish as first put on the market. The approximate aggregate weight of the output is 1,916,427,600 pounds, including only the soft parts of products like oysters, clams, scallops, etc.

Following is a summary showing the rank of the different States as regards persons employed, capital invested, and value of products. The years to which the figures in this and the following tables relate are, for the New England States, 1898; for the Middle Atlantic States, 1901; for the South Atlantic and Gulf States, 1897; for the Pacific States, Great Lakes, and interior waters, 1899; for Alaska, 1900. The statistics have been supplied by the Bureau of Fisheries, Department of Commerce and Labor.

A characteristic feature of the New England fisheries is the employment of a large fleet of fine schooner-rigged vessels in the offshore fisheries for cod, haddock, hake, halibut, and mackerel. Cod is the principal fish so taken, part of the catch being made on the Grand Banks and other banks lying off Newfoundland and Nova Scotia, and part on the very extensive and prolific banks adjacent to the New England shore, the most noted of which is Georges Bank. The most important of the New England boat and shore fisheries are those for sea-herring (caught chiefly in brush weirs), lobsters (caught in pots made of laths), soft-shell clams, and oysters. In the catch of herring, soft-shell clams, and lobsters, Maine surpasses all other States.

The oyster industry of the Middle Atlantic States gives to that region the importance which its fisheries have attained. The principal oyster grounds are in Long Island Sound, Delaware Bay, and Chesapeake Bay, a large part of the output now being taken from planted beds. An immense fleet of sailing vessels and boats is engaged in dredging and tonging oysters and running them to market. Other important salt-water products of this section are blue-fish, menhaden, sea bass, squeteague, hard clams, and crabs. The anadromous fishes, the shad, the alewives, and the striped bass, support valuable fisheries. The South Atlantic region has no noteworthy vessel fisheries, but its pound-net, gill-net, and seine fisheries for alewives, shad, sea mullet, and squeteague are important, shad being the leading product. The most prominent products of the Gulf States are mullet, red snappers, squeteague, oysters, shrimp, and sponges.

The Pacific States have very important vessel fisheries addressed to cod, halibut, and whales, and very extensive shore fisheries for salmon, herring, and oysters. The salmon fishery is the most valuable in the world, immense quantities of quinnat, blue-back, silver, and other salmon being caught in the Sacramento and Columbia rivers, in Puget Sound, and in Alaska. Much of the yield is canned. The salmon output of 1902 exceeded 248 million pounds.

The fisheries of the Great Lakes are the most important lake fisheries in the world, those in the United States waters producing over 100,000,000 pounds of excellent food fish annually. Lake Erie has the largest catch, closely followed by Lake Michigan. The principal fishes are whitefish, lake herring or cisco, lake trout, pike perch, and yellow perch. The numerous interior waters of the country are well supplied with economic animals and support valuable fisheries. The most productive waters are the Mississippi River and tributaries. The species figuring most conspicuously in the catch are black bass, buffalo-fish, carp, crappies, suckers, frogs, and mussels, the shells of the last named being extensively used in making pearl buttons.

The table on the following page shows the extent of the fisheries in each of the foregoing geographical divisions:

The products of the United States fisheries may be classified as follows.

Products	Value
Food-fishes in general	$27,889,588
Menhaden (for oil and guano)	973,200
Whales, seals, and other mammals	1,321,247
Turtles, terrapin, alligators, frogs	254,922
Oysters and other mollusks	16,700,524
Lobsters and other crustaceans	2,251,869
Sponges	305,589
Total	$49,696,939

United States Insular Possessions.— In 1900 the fisheries of Hawaii gave employment to 2,345 people, of whom 1,571 were natives, 485 Japanese, and 238 Chinese. The value of fishing property was $272,591. The catch comprised 6,222,455 pounds of fish and other products, mostly eaten fresh, and was valued at $1,083,646. The Philippine Islands have valuable fishing resources which are but little developed. The leading fishery is that for pearls and pearl shells in the Sulu archipelago; from time immemorial the pearls from this region have been famous. No statistics are available. The fisheries of Porto Rico are comparatively unimportant, although capable of development; at present the catch is only for local consumption and is eaten fresh.

Canada.— The fisheries of the Dominion of Canada are very extensive and closely resemble those of the United States. The aggregate yield

FISHERIES OF THE UNITED STATES ACCORDING TO GEOGRAPHICAL SECTIONS.

Sections	Persons employed			Vessels				Boats		Apparatus of capture	Shore property	Cash capital	Total investment	Products

in 1901, according to official statements, was $25,737,153, which includes the value of canned products and hence exceeds by several million dollars the actual value of the fisheries proper. The number of persons engaged in 1901 was about 93,000, and the capital invested was $11,491,000. The fisheries of Nova Scotia are more extensive than those of the other provinces; here cod, haddock, herring, mackerel, and lobsters are taken in large quantities. New Brunswick and Quebec have fisheries similar to those of Nova Scotia, while Ontario and Manitoba have important fresh-water fisheries for whitefish, trout, and other lake species. The fisheries of British Columbia, which rank next to those of Nova Scotia, are addressed chiefly to salmon. The principal catch is in the Fraser River. See CANADA — FISHERIES.

Newfoundland.— In proportion to population, the fisheries of this island are more valuable than those of any other country. The value of fishery products exported in 1902 was $7,777,305, and the value of products consumed locally was estimated at $1,000,000. The leading fish are cod and herring, the cod fishery being more valuable than in any other country. The hair-seal fishery is another branch in which Newfoundland leads.

Great Britain and Ireland.— The fisheries of the British Isles surpass those of any other country of Europe, and are about equal to those of the United States. Besides extensive coast fisheries, there are very important offshore vessel fisheries for cod, haddock, herring, and flatfishes, gill-nets being set for herring and beam trawls used for the other species. In 1901, 106,477 persons found employment in fishing, of which 39,566 were in England and Wales, 37,394 in Scotland, and 27,947 in Ireland. The registered fishing vessels and boats numbered 25,797. In 1901, the fisheries of England and Wales were valued at $33,212,800; Scotland, $11,252,000; Ireland, $1,813,900 — a total of $46,278,700.

Russia.— This country has vast fishery resources, and the annual catch exceeds in value that of any other country of Europe except Great Britain. The ocean fisheries are insignificant, but those of the Caspian Sea and the fresh waters, especially the Ural and Volga rivers are very highly developed. The herring fisheries of the Caspian Sea are famous, and millions of pounds are caught annually. The sturgeon and the pike perch fisheries are the most valuable in the world. The roach is so abundant and cheap that it may be considered the national fish; between 200,000,000 and 300,000,000 pounds are taken annually in the Caspian Sea. Other important products are carp, catfish, bream, whitefish, yellow perch, and lampreys. Accurate statistics are lacking, but a Russian official estimate gives an annual catch of 1,500,000,000 pounds, valued at $25,000,000.

France.— Fisheries of great magnitude are prosecuted in the coast waters of France and by French fishermen in Newfoundland, Iceland, and the North Sea. In 1900 the number of vessel and boat fishermen was 96,413 and of shore fishermen 61,979; and the value of the products taken was $21,240,000. In the cod fisheries of Newfoundland, Iceland, and the North Sea, 44,565,234 kilograms of fish, valued at $3,793,550 were caught; and in the high-sea fisheries 56,227,289 kilograms of herring, mackerel, and other fish, valued at $5,509,997, were taken. The principal coast fishery is that for sardines, large quantities of which are canned and sent to all parts of the world; the quantity taken (1900) was 40,192,817 kilograms, worth $2,361,182. Other valuable products are tunny, lobsters, spiny lobsters, crayfish, oysters, mussels and seaweeds. The cultivation of oysters has reached great perfection and upward of 1,000,000,000 oysters, grown in artificial enclosures, are marketed annually.

Norway.— More than 120,000 people are employed in the Norwegian fisheries. The principal products are cod, valued at $3,660,000 in 1900; herring, valued at $2,440,000; and salmon and trout, valued at $280,000. The cod fishery is carried on chiefly at the Lofoten Islands, where 35,000 fishermen are engaged. Other important fisheries are the lobster, whale, seal, and shark. The total value of the fisheries in 1900 was $7,900,000. A large part of the catch is exported to other European countries and the United States.

Other European Countries.— Germany has cod and herring fisheries, in the Baltic and North seas, and minor fresh-water fisheries. Upward of 32,000 persons are reported to be employed, and the annual catch is worth several million dollars, but definite statistics are not available. The Netherlands have valuable herring fisheries, which in 1901 yielded $1,478,000. Other valuable products are cod, anchovy, and oysters. The yearly production is valued at about $2,000,000. The fisheries of Denmark were valued at $1,995,000 in 1900. The fishermen of Belgium catch chiefly herring and cod, the output being about $1,250,000 annually. Portugal has 4,000 vessels and boats, mostly engaged in the sardine and tunny fisheries; the products taken in 1898 had a value of $4,182,000. The fisheries of Spain are estimated to be worth $2,500,000, but no definite information regarding them is obtainable. Italy has nearly 100,000 fishermen engaged in the tunny, coral, sponge, and general food-fish fisheries. The aggregate value of water products is estimated at $3,500,000 yearly. The Swedish fisheries were valued at $2,056,000 in 1896. The principal species sought is the herring; the herring fishery of Bohuslän is famous, employing 7,500 men. Other important products are cod, mackerel, eels, salmon, and lobsters. The sea fisheries of Austria-Hungary in 1901 gave employment to 15,300 persons, and yielded $1,405,000 worth of fish, etc. Greece and Turkey have valuable sponge fisheries.

Japan.— The fisheries of Japan are in some respects the most important in the world, and in value rank next to those of the United States and Great Britain. While complete statistics are lacking, it is known that about 400,000 vessels and boats are employed and that in 1901 2,508,000 persons were engaged in fishing. All the coast waters abound in excellent food fishes, mollusks, crustaceans, and other products, together with many objects used for ornamental, artistic, and other purposes beside for food. The leading products are sardines (of which 500,000,000 pounds are annually caught), herring, tai, bonito, mackerel, tunny, salmon, cod, squid, coral, and algæ. The herring, salmon, cod, and other fisheries of Hokkaido, the most northern of the main islands, are very extensive, yielding nearly 1,000,000,000 pounds. The aggregate output of the Japanese fisheries is probably not less than 2,000,000,000 pounds a year, with an estimated value of $30,000,000. GEORGE M. BOWERS,

Bureau of Fisheries, Washington.

Fisheries Question. The provinces of British North America in 1760–76 enjoyed mutual fishing rights on the entire North Atlantic coast, but when the Revolution severed Canada from the rest of the seaboard, Great Britain proposed to deny the United States the right to fish there, on the ground of Canadian opposition. As this meant ruin to a great New England industry, the Canadian waters being the cream of the fishing grounds, John Adams refused to sign the Treaty of Paris (7 Sept. 1783) until the right was granted, though his fellow commissioners would have sacrificed them; and his stubbornness secured their retention. Fishing could still go on; but we could not dry or cure fish on the coast of Newfoundland, or the settled coasts or river-banks of Nova Scotia, the Magdalen Islands, or Labrador, except by agreement with the inhabitants. Under these provisions, the energetic American fishermen occupied many excellent fishing stations along the Canada shore; to the envy and dissatisfaction of the British; and when the War of 1812 broke out, the latter seized the opportunity to declare the Treaty of Paris abrogated, and order the Canadian officials to refuse American fishermen access to the grounds. The Americans declared the fishery provisions of the Treaty unvoidable. The Treaty of Ghent, of 1814, ignored this question, as it did so much else of vital import, and the old rights were tacitly allowed to stand. But in 1818 a joint convention at London revised the fishing provisions: the United States were to have the right only of fishing in the deep sea at least three miles from shore, except on the western and northern coast of Newfoundland and the Magdalens; but could dry and cure on the coasts as before, and enter bays and harbors for wood or water or for refuge. But the three-mile provision was the bone of contention it has always been, as to headlands, etc., and here as to the Gut of Canso — in effect, the American right to fish in the Gulf of St. Lawrence, Chaleurs Bay, or the Bay of Fundy; as to the latter, an American vessel was seized for fishing in it, and on arbitration the American claim was held valid. Finally, the Reciprocity Treaty of 1854 abolished all mutual restrictions on deep-sea fishing except for shellfish. The United States abrogated this treaty in 1866, and conditions reverted to those of 1818, but the Treaty of Washington in 1871, to take effect in 1873, revived it again in full down to lat. 39° N. The Canadians, however, asserted that their waters were much the more valuable, and on arbitration provided for in the treaty, they were awarded $5,500,000 in 1877, on a claim of $14,280,000. In 1885 the United States again abrogated reciprocity, under pressure from fishing interests, and returned to the 1818 status with its disputed meanings. Our fishing vessels were seized as before; and in 1887 Congress authorized the President at his discretion to lay an embargo on all Canadian commerce to American ports, which, however, has not been done. In 1888 the Chamberlain-Bayard Treaty arranged these difficulties, but the Senate rejected it; in 1890, however, the Canadian government embodied it in its laws. A joint high commission to settle the question met in Washington in 1899, but adjourned without coming to a decision. In all cases, however, the provisions of the Convention of London, 1818, is held by both governments as binding in absence of special treaties overriding them. The crucial point has always been and is likely to be the "headland doctrine." The Americans claim that it should not be recognized, but the curves of the coast followed instead of drawing the line from headland to headland; the Canadians say it is vital to the protection of their own fishermen.

Fisher's Hill, about 20 miles south of Winchester, Va., between the Massanutten and North Mountains, and with its base washed by a branch of the Shenandoah. This place was the scene of an action, 22 Sept. 1864, between a National force under Gen. Sheridan, and one of Confederates commanded by Gen. Early.

Fisher's Hill, Battle of. Gen. Early was defeated at the battle of the Opequon, Va., 19 Sept. 1864, and retreated during the night, 20 miles up the Shenandoah Valley to Fisher's Hill, two miles south of Strasburg, Va. Gen. Sheridan followed at daylight of the 20th up the Valley pike, Gen. Wilson's cavalry division covering his left and Gen. Averell's division on his right. During the afternoon of the 20th Wright's Sixth corps and Emory's Nineteenth corps arrived at Cedar Creek, crossed and took position on the heights fronting Strasburg. Crook's Eighth corps halted on the left bank of the creek. On 21 Sept. Sheridan pushed through the town, drove Early's skirmishers to the entrenchments and reconnoitered the position, which, naturally strong, Early had strengthened with works of earth and stone, behind which was Wharton's division on the right, then Gordon's, Pegram's, and Ramseur's, with Lomax's division of dismounted cavalry on the extreme left. Fitz Hugh Lee's cavalry was at Millford, 12 miles above Front Royal, guarding Luray Valley and Early's right. Sheridan ordered Gen. Torbert, with Merritt's and Wilson's cavalry divisions, to the Luray Valley to drive out any force of the enemy in that quarter, and cross over from the valley to New Market, and intercept Early's retreat. During the afternoon the Sixth corps, after a serious repulse, succeeded in gaining a commanding position near the Confederate works, which was immediately entrenched and artillery put in position. Early's right was too strongly posted to attack in front, so Sheridan concluded to turn and attack his left. During the night of the 21st Crook crossed Cedar Creek and, hidden in a clump of timber, remained until daylight, when, under cover of woods and ravines, he marched in rear of and beyond the right of the Sixth corps, and was again concealed, while Rickett's division of the Sixth corps was pushed out and confronted the left of Early's infantry, ready to join Crook's left when he should attack. While Rickett's was threatening in front Crook marched unobserved into the dense timber on the eastern face of Little North Mountain, until he gained the rear of Early's works when, facing to the left, he marched down the mountain side, at sunset. He was seen by Lomax, artillery was turned upon him, but too late; he struck Lomax's dismounted men in flank and rear, driving them back on Ramseur, who endeavored to change front, but Rickett's division advancing struck Ramseur in the act, joined Crook's left, and the two commands moved along in rear of Early's entrenchments, his men giving way all along the line, abandoning many guns. The swinging movement of Rickett's division on the right was taken up from right to left, and between sunset and darkness Early's entire army was defeated and in disorderly retreat. Early reported next morning to Gen. Lee that the enemy "succeeded in driving back the left of my line which was defended by the cavalry, and throwing a force in the rear of the left of my infantry, when the whole of the troops gave way in a panic and could not be rallied." Early retreated four miles beyond Woodstock and Sheridan pursued him all night, to Woodstock, 12 miles, which was reached at daybreak next morning. The Union loss was 509 killed and wounded. Early reported a loss in infantry and artillery of 240 killed and wounded and 995 missing. The loss in Lomax's cavalry would swell the entire Confederate loss to about 1,400.

E. A. Carman.

Fisher's Island, at the entrance of Long Island Sound, near Connecticut. The island is in the State of New York; it is a part of the Southold township, in Suffolk County, N. Y. Area 4,000 acres.

Fishes, Geographical Distribution of. The laws governing the distribution of animals are reducible to three very simple propositions. Each species of animal is found in every part of the earth having conditions suitable for its maintenance, unless:

(*a*) Its individuals have been unable to reach this region through barriers of some sort; or,

(*b*) Having reached it, the species is unable to maintain itself, through lack of capacity for adaptation, through severity of competition with other forms, or through destructive conditions of environment; or else,

(*c*) Having entered and maintained itself, it has become so altered in the process of adaptation as to become a species distinct from the original type.

Under the first head, numerous illustrations may be given. The absence of loaches in America and of mooneyes in Europe may serve as examples.

Of species under (*b*), those who have crossed the seas and not found lodgment, there is, in the nature of things, no record. Of the existence of multitudes of estrays there is abundant evidence. Now and then one among thousands finds permanent lodgment, and by such means a species from another region will be added to the fauna. The rest disappear and leave no trace. A knowledge of the currents of the sea and their influence is essential to any detailed study of the dispersion of fishes.

In the third class, that of species changed in the process of adaptation, most insular forms belong. As a matter of fact, at some time or another almost every species must be in this category, for isolation is a source of the most potent elements in the initiation and intensification of the minor differences which separate related species. It is not the preservation of the most useful features, but of those which actually existed in the ancestral individuals, which distinguished such species. In many cases the persistence of characters rests not on any special usefulness or fitness, but on the fact that individuals possessing these characters have, at one time or another, invaded a certain area and populated it.

Barriers Checking Movement of Fishes.—The limits of the distribution of individual species or genera must be found in some sort of barrier, past or present. The chief barriers which limit marine fishes are the presence of land, the presence of great oceans, the differences of temperature arising from differences in latitude, the nature of the sea-bottom, and the direction of oceanic currents. That which is a barrier to one species may be an agent in distribution to another. The common shore-fishes would perish in deep waters almost as surely as on land, while the open Pacific is a broad highway to the albacore or the swordfish.

Again, that which is a barrier to rapid distribution may become an agent in the slow extension of the range of a species. The vast continent of Asia is undoubtedly one of the greatest of barriers to the wide movement of species of fish, yet its long shore-line enables species to creep, as it were, from bay to bay, or from rock to rock; till, in many cases, the same species is found in the Red Sea and in the tide-pools or sand-reaches of Japan, or even in the brooks or coral pools of Tahiti or Samoa. In the North Pacific the presence of a range of half-submerged volcanoes, known as the Aleutian and the Kurile Islands, has greatly aided the slow movement of the fishes of the tide-pools and the kelp. To a school of mackerel or of flying-fishes these rough islands might form an insuperable barrier.

Temperature the Central Fact.—It has long been recognized that the matter of temperature is the central fact in all problems of geographical distribution. Few species in any group freely cross the frost-line, and except as borne by oceanic currents, few species extend their range far into waters colder than those in which the species is distinctively at home. Knowing the average temperature of the water in a given region, we know in general the types of fishes which must inhabit it. It is the similarity in temperature and physical conditions, not the former absence of barriers, which chiefly explains the analogy of the Japanese fauna to that of the Mediterranean or the Antilles. This fact alone must explain the resemblance of the Arctic and Antarctic faunæ. Like forms lodge in like place.

Ocean Currents.—We may consider again for a moment the movements of the great currents in the Pacific as agencies in the distribution of species.

A great current sets to the eastward, crossing the ocean just south of the tropic of Cancer. It extends between the Gilbert and the Marshall islands and passes on nearly to the coast of Mexico, touching the Galapagos Islands, Clipperton Island, and especially the Revillagigedos. This may account for the number of Polynesian species found on these islands, about which they are freely mixed with immigrants from the mainland of Mexico.

From the Revillagigedos the current moves northward, passing the Hawaiian Islands and thence onward to the Ladrones. The absence in Hawaii of many of the characteristic fishes of the Samoan Islands and the Gilbert Islands is perhaps due to the long detour made by these currents, as the conditions of life in these groups of islands are not very different. Northeast of Hawaii is a great spiral current, moving with the hands of the watch, forming what is called Fleurieu's Whirlpool. This does not reach the coast of California. This fact may account for the almost complete distinction in the shore-fishes of Hawaii and California.

It is, of course, not necessary that the movements of a species in an oceanic current should coincide with the direction of the current. Young fishes, or fresh-water fishes, would be borne along with the water. Those that dwell within floating bodies of seaweed would go whither the waters carry the drifting mass. But free-swimming fishes, as the mackerel or flying-fishes, might as readily choose the reverse direction. To a free-swimming fish, the temperature of the water would be the only consideration. It is thus evident that a current which to certain forms would prove a barrier to distribution, to others would be a mere convenience in movement.

Centres of Distribution.—We may assume, in regard to any species, that it has had its origin in or near that region in which it is most abundant and characteristic. Such an assumption must involve a certain percentage of error or of doubt, but in considering the mass of species, it would represent essential truth. In the same fashion, we may regard a genus as being autochthonous or first developed in the region where it shows the greatest range or variety of species. Those regions where the greatest number of genera are thus autochthonous may be regarded as centres of distribution. So far as the marine fishes are concerned, the most important of these centres are found in the Pacific Ocean. First of these in importance is the East Indian Archipelago, with the neighboring shores of India. Next would come the Arctic Pacific and its bounding islands, from Japan to British Columbia. Third in importance in this regard is Australia. Important centres are also found in temperate Japan, in California, the Panama region, and in New Zealand, Chile, and Patagonia. The fauna of Polynesia is almost entirely derived from the East Indies; and the shore fauna of the Red Sea, the Bay of Bengal and Madagascar, so far as genera are concerned, seems to be not really separable from the Indian fauna generally.

In the Atlantic the chief centre of distribution is the West Indies; the second is the Mediterranean. On the shores to the northward or southward of these regions occasional genera have found their origin. This is true especially of the New England region, the North Sea, the Gulf of Guinea, and the coast of Argentina. The fish-fauna of the North Atlantic is derived mainly from the North Pacific, the differences lying mainly in the lower richness of the North Atlantic. But, in certain groups common to the two regions, the migration must have been in the opposite direction; exceptions that prove the rule.

Realms of Fresh-Water Distribution.—If we consider the fresh-water fishes alone we may divide the land areas of the earth into districts and zones, fairly agreeing with those marked out for mammals and birds. The river-basin, bounded by its water-sheds and the sea at its mouth, shows many resemblances, from the point of view of a fish, to an island considered as the home of an animal. It is evident that with fishes the differences in latitude outweigh those of continental areas, and a primary division into Old World and New World would not be tenable.

The chief areas of dispersion of fresh-water fishes may be indicated as below, following essentially the grouping proposed by Dr. Günther.

Northern Zone (Arctic and Temperate): With Dr. Günther, we may recognize, first the Northern Zone characterized familiarly by the presence of sturgeon, salmon, trout, whitefish, pike, lamprey, stickleback, and other species of which the genera and often the species are identical in Europe, Siberia, Canada, Alaska, and most of the United States, Japan, and China.

Equatorial Zone: The Equatorial Zone is roughly indicated by the tropics of Cancer and Capricorn. Its essential feature is that of the temperature, and the peculiarities of its divisions are caused by barriers of sea or mountains.

Dr. Günther finds the best line of separation into two divisions to lie in the presence or absence of the great group of dace or minnows, (*Cyprinidæ*), to which nearly half of the species of fresh-water fishes the world over belong. The entire group, now spread everywhere except in the Arctic, South America, Australia, and the islands of the Pacific, had its origin in India, from which its genera have radiated in every direction.

The Cyprinoid division of the Equatorial Zone forms two districts, the Indian and the African. The Acyprinoid division includes South America, south of Mexico, and all the islands of the tropical Pacific lying to the east of Wallace's line. This line, separating Borneo from Celebes and Bali from Lompoe, marks in the Pacific the western limit of cyprinoid fishes, as well as that of monkeys and other important groups of land animals. This line, recognized as very important in the distribution of land animals, coincides in general with the ocean current between Celebes and Papua, which is one of the sources of the Kuroshiwo.

Southern Zone: The third great region, the Southern Zone, is scantily supplied with fresh-water fishes, and the few it possesses are chiefly derived from modifications of the marine fauna or from the Equatorial Zone to the north. Three districts are recognized, Tasmanian, the New Zealand and the Patagonian.

Faunal Resemblances.— There are two main sources of faunal resemblances; first, the absence of barriers permitting the actual mingling of the species; second, the likeness of temperature and shore configuration favoring the lodgment or development of the same or analogous types. If the fish-faunas of different regions have mingled in recent times the fact would be shown by the presence of the same species in each region. If the union were of remote date the species would be changed, but the genera might remain identical.

In case of close physical resemblances in different regions, as in the East Indies and West Indies, like conditions would favor the lodgment of like types, but the resemblance would be general, the genera and species being unlike. Without doubt part of the resemblance between Japan and the Mediterranean is due to similarity of temperature and shores.

Direction of Shore-Line.— We may first note that a continuous shore-line produces a mingling of fish-faunas only when not interrupted by barriers due to climate. A north and south coast-line, like that of the East Pacific, however unbroken, permits great faunal differences. It is crossed by the different zones of temperature. An east and a west shore-line lie in the same temperature. In all cases of the kind which now exist on the earth (the Mediterranean, the Gulf of Mexico, the Caribbean Sea, the shores of India), most species will extend their range as far as the shore-line goes. The obvious reason is because such a shore-line rarely offers any important barrier to distribution, checking dispersion of species.

Genera in Different Faunas.— For our purposes, the genera must be rigidly defined, a separate name being used in case of each definable difference in structure. The wide-ranging genera of the earlier systematists were practically cosmopolitan, and their distribution teaches us little. Using the modern definition of genus, we find in Japan 483 genera of marine shore-fishes; in the Red Sea, 225; in the Mediterranean, 231. In New Zealand 150 are recorded; in Hawaii, 171; 357 from the West Indies, 187 from the Pacific coast of tropical America, 300 from India, 450 from the East-Indian islands and 427 from Australia.

Of the 483 genera ascribed to Japan 156 are common to the Mediterranean also, 188 to the West Indies and Japan, 169 to the Pacific coast of the United States and Mexico. With Hawaii Japan shares 90 genera, with New Zealand 62; 204 are common to Japan and India, 148 to Japan and the Red Sea, most of these being found in India also; while 200 genera are common to Japan and Australia.

From this, it is evident that Japan and the Mediterranean have much in common, but apparently not more than Japan shares with other tropical regions. Japan naturally shows most likeness to India, and next to this to the Red Sea. Proportionately less is the resemblance to Australia, and the likeness to the Mediterranean seems much the same as that to the West Indies, or to the Pacific coast of America. But, to make these comparisons just and effective, we should consider not the fish-fauna as a whole; we should limit our discussions solely to the forms of equatorial origin. We should eliminate all pelagic and all deep-sea forms, for the laws which govern the distribution of these are very different from those controlling the shore-fishes, and most of the genera have reached a kind of equilibrium over the world. We may note also, as a source of confusion in our investigation, that numerous forms found in Japan and elsewhere are very rarely taken, and their real distribution is unknown. Some of these will be found to have, in some unexpected quarter, their real centre of dispersion. Such

12. Fall-fish.

species may inhabit oceanic plateaus, and find many halting places in their circuit of the tropical oceans.

Extension of Indian Fauna.—From statistical tables representing the distribution of genera it is evident that the warm-water fauna of Japan, as well as that of Hawaii, is derived from the great body of the fauna of the East Indies and Hindustan; that the fauna of the Red Sea is derived in the same way; that the fauna of the Mediterranean bears no especial resemblance to that of Japan, rather than to other elements of the East Asiatic fauna in similar conditions of temperature, and no greater than is borne by either to the West Indies; that the faunas of the sides of the Isthmus of Suez have relatively little in common, while those of the two sides of the Isthmus of Panama show large identity of genera, although few species are common to the two sides. Of the 255 genera recorded from the Panama region 179, or over 70 per cent, are also in the West Indies; while 68, or more than 30 per cent of the number, are limited to the two regions in question.

The Isthmus of Suez as a Barrier.— With free connection across the Isthmus of Suez, the fauna of the Red Sea must have been once practically the same as that of the Mediterranean. The present differences must be due to later immigrations to one or the other region, or to the extinction of species in one locality or the other, through some kind of unfitness. In neither region is there evidence of extensive immigration from the outside. The present conditions of water and temperature differ a little, but not enough to explain the difference in faunas. The Red Sea is frankly tropical and its fauna is essentially Indian, much the same, so far as genera are concerned, as that of southern Japan. The Mediterranean is at most not more than semi-tropical, and its fishes are characteristically European. Its tropical forms belong rather to Guinea than to the East Indies. With the Red Sea the Mediterranean has very little in common, not so much, for example, as has Hawaii, much less than has Samoa. Forty genera of shore-fishes (and only 50 of all fishes) are identical in the two regions, the Mediterranean and the Red Sea. Of those, every one is a genus of wide distribution, found in nearly all warm seas. Of shore-fishes, only one genus in seven is common to the two regions. Apparently, therefore, we cannot assume a passage across the Isthmus of Suez within the lifetime of the present genera. Not one of the types alleged to be peculiar to Japan and the Mediterranean is thus far known in the Red Sea. Scarcely any of the characteristically abundant Mediterranean types crosses the Isthmus of Suez, and the distinctive Red Sea and Indian types are equally wanting in the Mediterranean. The only genera which could have crossed the Isthmus are certain shallow-water or brackish-water forms, sting-rays, torpedoes, sardines, eels, and mullets, widely diffused through the East Indies and found also in the Mediterranean. The former channel, if one ever existed, had therefore much the same value in distribution of species as the present Suez Canal.

Submersion of the Isthmus of Suez.— Yet, from geological data, there is strong evidence that the Isthmus of Suez was submerged in relatively recent times. The recognized geological maps of the isthmus show that a broad area of post-Pliocene or Pliocene deposits constitutes the isthmus and separates the nummulitic hills of Suez from their fellows about 30 miles to the eastward. The northern part of the isthmus is alluvium from the Nile, and its western part is covered with drifting sands. The Red Sea once extended farther north than now, and the Mediterranean farther to the southeast. Assuming the maps to be correct, the isthmus must have been open water in the late Pliocene or post-Pliocene times.

Admitting this as a fact, the difference in the fish-fauna shows that the waters over the submerged area must have been so shallow that rock-loving forms did not and could not cross it. Moreover, the region must have been overspread with silt-bearing fresh waters from the Nile. To the reef-loving fishes of the Red Sea, or of the Mediterranean, such waters would form a barrier as effective as the sand-dunes of to-day.

In earlier times the Mediterranean must have been directly connected with the Indian Ocean. This is shown from the abundance of Indian types now extinct in Europe, in the Eocene deposits of Italy.

We are therefore led to these conclusions:

1. There is no evidence, derivable from the fishes, of the submergence of the Isthmus of Suez since Miocene times.
2. If the isthmus was submerged in Pliocene or post-Pliocene times the resultant channel was shallow and muddy, so that ordinary marine fishes or fishes of rock-bottoms, or of deep waters, did not cross it.
3. It formed an open water-way to brackish-water fishes only.
4. The types common to Japan and the Mediterranean did not enter either region from the other, by way of the Red Sea, at least not in recent times.
5. As most of these are found also in India or Australia or both, their dispersion was probably around the south coast of Africa or by the Cape of Good Hope.
6. In Eocene times the Mediterranean and the Indian Ocean were fully connected.

We may then conclude that the resemblance of the Mediterranean fish-fauna to that of Japan or India is no more than might be expected, the present contour of the continents being permanent for the period of duration of the present genera and species. The imagined removal of barriers on any large scale would necessitate much closer resemblances than those which actually exist.

Isthmus of Panama as a Barrier.— Conditions in some regards parallel with those of the Isthmus of Suez exist in but one other region — the Isthmus of Panama. Here the first observers were very strongly impressed by the resemblance of forms. Nearly half the genera found on the two sides of this isthmus are common to both sides. Taking those of the Pacific shore for first consideration, we find that three fourths of the genera of the Panama fauna occur in the West Indies as well. This identity is many times greater than that existing at the Isthmus of Suez. Moreover, while the Cape of Good Hope offers no impassable barrier to distribution, the same is not true of the southern part of South America. The subarctic climate of Cape Horn has doubtless formed a complete check to the movements of tropical fishes for a vast period of geologic time.

But curiously enough, this marked resemblance is confined chiefly to the genera, and does not extend to the species on the two shores. Of 1,400 species of fishes recorded from tropical America north of the equator, only about 70 are common to the two coasts. The number of shore-fishes common is still less. In the 70 are included a certain number of cosmopolitan types which might have reached either shore from the Old World. A few others invade brackish or fresh waters and may possibly have passed, in one way or another, across the Isthmus of Nicaragua. Of fishes strictly marine, strictly littoral, and not known from Asia or Polynesia, scarcely any species are left as common to the two sides. This seems to show that no waterway has existed across the isthmus within the lifetime, whatever that may be, of the existing species. The close resemblance of genera shows apparently with almost equal certainty that such a waterway has existed, and within the period of existence of the groups called genera. How long a species of fish may endure unchanged no one knows, but we know that in this regard great differences must exist in different groups. Assuming that different species crossed the Isthmus of Panama in Miocene times, we should not be surprised to find that a few remain to all appearances unchanged; that a much larger number have become "representative" species, closely related forms retaining relations to the environment of those of the parent form, and, finally, that a few species have been radically altered.

This is exactly what has taken place at the Isthmus of Panama with the marine shore-fishes, although, curiously enough, the movement of genera seems to have been chiefly from the Atlantic to the Pacific.

As to the localities inhabited by fishes, we may roughly divide the species into marine species and fresh-water species. The marine species may be again divided into three main categories according to differences in vertical distribution, the pelagic, bassalian and littoral fishes.

Pelagic Fishes.— Pelagic fishes are those inhabiting the open sea and ranging widely within given limits of temperature. In this series some species are practically cosmopolitan. In other cases the genera are so. Each school or group of individuals has its breeding-place, and from the isolation of breeding-districts new species may be conceived to arise. The pelagic types have reached a species of equilibrium in distribution. Each type may be found where suitable conditions exist, and the distribution of species throws little light on questions of distribution of shore-fishes. Yet among these species are all degree of localization. The pelagic fishes shade into the shore-fishes on the one hand and into the deep-sea fishes on the other.

Bassalian Fishes.— The vast group of bassalian or deep-sea fishes includes those form which live below the line of adequate light. These, too, are localized in their distribution, and to a much greater extent than was formerly supposed. Yet, as they dwell below the influence of the sun's rays, zones and surface temperatures are nearly alike to them, and the same forms may be found in the arctic or under the equator. Their differences in distribution are largely vertical, some living at greater depths than others, and they shade off by degrees from bathybial into semi-bathybial, and finally into ordinary pelagic and ordinary shore-types. See Deep-sea Life.

Littoral Fishes.— The shore-fishes are in general the most highly specialized in their respective groups, because exposed to the greatest variety of selecting conditions and of competition. Their distribution in space is more definite than that of the pelagic and bassalian types, and they may be more definitely assigned to geographical areas.

Distribution by Coast-lines.— The distribution of littoral fishes is best indicated not by realms or areas, but as forming four parallel series, corresponding to the four great north and south continental outlines. Each of these series may be represented as beginning at the north in the Arctic fauna, practically identical in each of the four series, actually identical in the two Pacific series. Passing southward, forms are arranged according to temperature. One by one in each series, the Arctic types disappear; subarctic, temperate, and semi-tropical types take their places, giving way in turn to south-temperate and Antarctic forms. The distribution of these is modified by barriers and by currents, yet though genera and species may be different, each isotherm is represented in each series by certain general types of fishes.

Distribution of Fresh-water Fishes.—As to their distribution in the streams, the fresh-water fishes may be subdivided as follows:

1. Lowland fishes; as the bowfin, pirate-perch, large-mouthed black bass, sun-fishes, and some catfishes.

2. Channel fishes: as the channel catfish, the mooneye, garpike, buffalo-fishes, and drum.

3. Upland fishes; as many of the darters, shiners and suckers, and the small-mouthed black bass.

4. Mountain fishes; as the brook-trout, and many of the darters and minnows.

To these we may add, (5) the more or less distinct classes of lake fishes, inhabiting only the waters which are deep, clear, and cold, as the various species of whitefish and the Great-Lake trout; (6) anadromous fishes, or those which run up from the sea to spawn in fresh waters, as the salmon, sturgeon, shad, and striped bass; (7) catadromous fishes, like the eel, which pass down to spawn in the sea; and (8) brackish-water fishes, which thrive best in the debatable waters of the river-mouths, as most of the sticklebacks and the killifishes.

As regards the range of species, we have every possible gradation from those which seem to be confined to a single river, and are rare even in their restricted habitat, to those which are in a measure cosmopolitan, ranging everywhere in suitable waters.

Still again, we have all degrees of constancy and inconstancy in what we regard as the characters of a species. Those found only in a single river-basin are usually uniform enough; but the species having a wide range usually vary much in different localities. Such variations have at different times been taken to be the indications of as many different species.

Where species can readily migrate their uniformity is preserved; but whenever a form becomes localized its representatives assume some characters not shared by the species as a whole. When we can trace, as we often can, the disappearance by degrees of these characters, such forms no longer represent to us distinct species. In cases where the connecting forms are extinct, or at least not represented in collections, each form which is apparently different must be regarded as a distinct species.

Barriers to River Fishes.— The existence of boundaries to the range of species therefore implies the existence of barriers to their diffusion. We may now consider these barriers and, in the same connection, the degree to which they may be overcome.

Least important of these are the barriers which may exist within the limits of any single basin, and which tend to prevent a free diffusion through its waters of species inhabiting any portion of it. In streams flowing southward, or across different parallels of latitude, the difference in climate becomes a matter of importance. The distribution of species is governed very largely by the temperature of the water. Each species has its range in this respect — the free-swimming fishes, notably the trout, being most affected by it; the mud-loving or bottom fishes, like the catfishes, least. The latter can reach the cool bottoms in hot weather, or the warm bottoms in cold weather, thus keeping their own temperature more even than that of the surface of the water. Although water communciation is perfectly free for most of the length of the Mississippi, there is a material difference between the faunas of the streams in Minnesota and in Louisiana. This difference is caused chiefly by the different temperature occupying the difference in latitude. That a similar difference in longitude, with free water communication, has no appreciable importance, is shown by the almost absolute identity of the fish-faunas of Lake Winnebago and Lake Champlain. While many large fishes range freely up and down the Mississippi, a majority of the species do not do so, and the fauna of the upper Mississippi has more in common with that of the tributaries of Lake Michigan than it has with that of the Red River or the Arkansas. The influence of climate is again shown in the paucity of the fauna of the cold waters of Lake Superior, as compared with that of Lake Michigan. The majority of our species cannot endure the cold. In general, therefore, cold or northern waters contain fewer species than southern waters do, though the number of individuals of any one kind may be greater. This is shown in all waters, fresh or salt. The fisheries of the northern seas are more extensive than those of the tropics. There are more fishes there, but they are far less varied in kind.

But in most streams the difference in latitude is insignificant, and the chief differences in temperature come from differences in elevation, or from the distance of the waters from the colder source. Often the lowland waters are so different in character as to produce a marked change in the quality of their faunas. These lowland waters may form a barrier to the free movements of upland fishes; but that this barrier is not impassable is shown by the identity of the fishes in the streams on the uplands of middle Tennessee with those of the Holston and French Broad. Again, streams of the Ozark Mountains, similar in character to the rivers of east Tennessee, have an essentially similar fish-fauna, although between the Ozarks and the Cumberland Range lies an area of lowland bayous, into which such fishes are never known to penetrate. We can, however, imagine that these upland fishes may be sometimes swept down from one side or the other into the Mississippi, from which they might ascend on the other side. But such transfers certainly do not often happen. This is apparent from the fact that the two faunas are not quite identical, and in some cases the same species are represented by perceptibly different varieties on one side and the other. The time of commingling of these faunas is perhaps now past, and it may have occurred only when the climate of the intervening regions was colder than at present.

The effects of waterfalls and cascades as barriers to the diffusion of most species is self-evident; but the importance of such obstacles is less, in the course of time, than might be expected. In one way or another very many species have passed these barriers. The falls of the Cumberland limit the range of most of the larger fishes of the river, but the streams above it have their quota of darters and minnows. It is evident that the past history of the stream must enter as a factor into this discussion, but this past history it is not always possible to trace. Dams and artificial waterfalls now check the free movement of many species, especially those of migratory habits; while, conversely, numerous other species have extended their range through the agency of canals.

Every year fishes are swept down the rivers by the winter floods; and in the spring, as the spawning season approaches, almost every species is found working its way up the stream. In some cases, notably that of the quinnat-salmon and the red salmon, the length of these migrations is surprisingly great. To some species rapids and shallows have proved a sufficient barrier, and other kinds have been kept back by unfavorable conditions of various sorts. Streams whose waters are charged with silt or sediment, as the Mississippi, Arkansas, or Brazos, do not invite fishes; and even the occasional floods of red mud, such as disfigure otherwise clear streams, like the Red River or the Colorado (of Texas), are unfavorable. Extremely unfavorable also is the condition which obtains in many rivers of the southwest; as for example, the Red River, the Sabine, and the Trinity, which are full from bank to bank in winter and spring, and which dwindle to mere rivulets in the autumn droughts.

In general, those streams which have conditions most favorable to fish-life will be found to contain the greatest number of species.

There can be no doubt that the general tendency is for each species to extend its range more and more widely until all localities suitable for its growth are included. The various agencies of dispersal which have existed in the past are still in operation. There is apparently no limit to their action. It is probable that new «colonies» of one species or another may be planted each year in waters not heretofore inhabited by such species. But such colonies become permanent only where the conditions are so favorable that the species can hold its own in the struggle for food and subsistence. That various modifications in the habitat of certain species have been caused by human agencies is of course too well known to need discussion here.

Of watersheds in the United States the most important and most effective is unquestionably that of the main chain of the Rocky Mountains. This is due in part to its great height, still more to its great breadth, and most of all, perhaps, to the fact that (Two Ocean Pass excepted) it is nowhere broken by the passage of a river. In the few cases when species have crossed this barrier a break in the chain (as the Two Ocean Pass in Wyoming connecting the Snake River with the Yellowstone) has now been recorded.

Habitat of Species.— Each species finds its habitat fitted to its life, and then in turn is forced to adapt itself to this habitat. Any other kind of habitat then appears as a barrier to its distribution. Thus to a fish of the ripples a stretch of still water becomes a barrier. A species adapted to sandy bottoms will seldom force its way through swift waters or among weeds or rocks.

The stream that has the greatest variety of animals in it would be one (1) connected with a large river; (2) in a warm climate; (3) with clear water, and (4) little fluctuation from winter to summer; (5) with little change in the clearness of the water; (6) a gravelly bottom; (7) preferably of limestone, and (8) covered in its quiet reaches and its ripples with water-weeds. These conditions are best realized in the tributaries of the Ohio, Cumberland, Tennessee, and Ozark rivers among American streams, and it is in them that the greatest number of species of fresh-water animals (fishes, crayfishes, mussels, etc.) has been recorded. These streams approach most nearly to the ideal homes for animals of the fresh waters. The streams of Wisconsin, Michigan, and the Columbia region have many advantages, but are too cold. Those of Illinois, Iowa, northern Missouri, and Kansas are too sluggish, and sometimes run muddy. Those of Texas and California shrink too much in the summer, and are too isolated. The streams of the Atlantic coast are less isolated, but none connect with a great basin, and those of New England run too cold for the great mass of the species. For similar reasons the fresh-water animal life of Europe is relatively scanty, that of the Danube and Volga being richest. The animal life of the fresh water of South America centres in the Amazon, and that of Africa in the Nile, the Niger, and the Kongo. The great rivers of Siberia, like the Yukon in Alaska and the Mackenzie River in British America, have but few forms of fresh-water animals, though those kinds fitted for life in cold, clear water exist in great abundance. See FISH; ICHTHYOLOGY.

DAVID STARR JORDAN,

President Leland Stanford, Jr., University.

Fishing Cat, a wild cat (*Felis viverrina*), native to eastern India and eastward. It is nearly three feet long, and has a tapering tail about a foot in length. It is dark-gray or brown, striped and spotted with darker color; the tail is barred, and the throat and breast are quite white. Though it is a fierce animal, and has been known to carry off infants, it lives, generally, by catching fish and shellfish.

Fishing Frog, a fish. See GOOSEFISH.

Fishing Laws. See GAME LAWS.

Fishkill Landing, or **Fishkill-on-Hudson,** N. Y., in Dutchess County; on the Hudson River, the New York C., and a branch of the New York, N. H. & H. R.R.'s. It is connected with the West Shore R.R., at Newburg, by ferry, and with many of the towns and cities along the Hudson River by electric railways. It is about 55 miles north of New York. It was used as a "landing" as early as the times of exploration along the Hudson, and the first settlement was made about the last of the 17th century. During the Revolution the New York Provincial Convention met here, and it shares with Newburg and Mattewan the distinction of being the military depot for supplies for the American troops and frequently the headquarters of Washington. When peace was restored, its advantages as a trading post for the settlements on the east side of the Hudson gave it opportunities that caused it to become quite a good-sized village in the early part of the 18th century. Its chief manufactures are the Corliss engines and rubber goods. Coal and food products are shipped here in large quantities from New York. In 1783 the Society of Cincinnati was organized here. Consult: 'New England Magazine,' No. 5, Vol. XIV., 'The Birthplace of the Order of Cincinnati'; Smith, 'History of Dutchess County.' Pop. (1900) 3,673.

Fishway, a device to enable fish, especially salmon, to ascend a fall. It may consist of a series of steps over which the water descends, turning a fall into a cascade, and sometimes known as a fish ladder; or it may consist of a chute for diminishing the velocity, and assisting the fish to the level above the dam.

Fisk, Clinton Bowen, American politician: b. Griggsville, N. Y., 8 Dec. 1828; d. New York 9 July 1890. In the Civil War he rose from private to brevet brigadier-general of volunteers 1865. He was assistant commissioner in the Freedmen's Bureau and founder of Fisk University, Nashville, Tenn., 1865, an institution for the education of colored persons of both sexes. He became a member of the Indian Commission 1873, joining the Prohibition party 1884, and running as its candidate for the governorship of New Jersey 1886, and for the presidency 1888.

Fisk, Franklin W., American educator: b. Hopkinton, Vt., 1820; d. Chicago 4 July 1901. He was graduated at Yale University in 1849; became professor of rhetoric in the Seminary of Beloit, Wis., and was called to the Chicago Theological Seminary when that school was founded in 1859. Subsequently he was president of the seminary till 1900, when he resigned.

Fisk, James, American stock speculator: b. Bennington, Vt., 1834; d. New York 1872. He became a member of the Boston mercantile firm of Jordan & Marsh, drove shrewd bargains with the government during the Civil War; later opened a broker's office in New York, and was employed with one Belden by Daniel Drew (q.v.) as agent in Drew's struggle with Cornelius Vanderbilt for control of the Erie Railway. The Drew-Fisk and Gould-Eldridge interests in concert succeeded in forcing out Vanderbilt and in placing Gould and Fisk in power, the former as president, the latter vice-president and comptroller of the road. The activity of the two in bribery and corruption involved State and Federal officials, and at its climax brought about the gold conspiracy of 1869 and the well-known "Black Friday" (24 Sept. 1869), when the efforts of the combination to corner the gold market resulted in financial panic. Fisk was shot after a quarrel by E. S. Stokes, a business associate.

Fisk, Wilbur, American Methodist clergyman and educator: b. Brattleboro, Vt., 31 Aug. 1792; d. 22 Feb. 1839. He was graduated from Brown University 1815, and a few years later entered the Methodist ministry. In 1825 he became the principal of the Wesleyan Academy at Wilbraham, an institution which had already under his auspices risen to considerable eminence, and continued in this position until 1830, when he was elected president of the Wesleyan University at Middletown, Conn., which under his charge became exceedingly popular. He was twice elected to the office of bishop, but declined both honors. He published 'Travels in Europe' (1838), and other works.

Fisk University, a coeducational institution in Nashville, Tenn.; founded in 1866 under the auspices of the Congregational Church; reported at the close of 1901: Professors and instructors, 30; students, 618; volumes in the library, 6,778.

Fiske, Amos Kidder, American editor and author: b. Whitefield, N. H., 12 May 1842. He was graduated at Harvard 1866, and admitted to the bar 1868. He collaborated with George Ticknor Curtis in the 'Life of Daniel Webster' and was a large contributor to the revised edition of the 'American Encyclopædia' (1873–6). He served for 20 years on the editorial staff of the New York *Times*, joining the staff of the *Mail and Express* 1900. His published works are: 'Midnight Talks at the Club' (1890); 'Beyond the Bourn' (1891); 'The Jewish Scriptures' (1896); 'The Myths of Israel' (1897); 'The Story of the Philippines' (1898); 'The West Indies' (1899).

Fiske, Bradley Allen, American naval officer: b. Lyons, N. Y., 13 June 1854. He was appointed a cadet midshipman in the United States navy in 1870; and became lieutenant-commander 30 March 1900. He invented a boat detaching and attaching apparatus for warships in 1877; the first electric ammunition used in the navy in 1888; electric gun-training apparatus and electric steering gear the same year; range- and position-finders in 1889; improvements of the range-finder and electric steering gear in 1895; and an electrical apparatus for transmitting the orders of a ship's commander from the deck bridge to the engine room in 1896; and has been attached to the Naval Bureau of Ordnance since 1895. Author: 'Electricity and Electrical Engineering'; 'Electricity in Theory and Practice.'

Fiske, Daniel Willard, American educator: b. Ellisburg, N. Y., 11 Nov. 1831; d. Frankfort-on-the-Main, Germany, 17 Sept. 1904. He studied at Hamilton College and in Europe, was an instructor in English and lecturer on American literature in the University of Upsala, Sweden, in 1849–52; member of the Astor Library (New York) staff 1852–9; and general secretary of the American Geographical Society in 1859–60. After having held a post in the Vienna legation (1861–2), he was editor of the Syracuse (N. Y.) *Journal* (1864–6), of the Hartford (Conn.) *Courant* (1867), and librarian-in-chief and professor of the languages of northern Europe in Cornell University. He removed to Florence, Italy, in 1881.

Fiske, John (originally **Edmund Fiske Green**), American historian and philosopher: b. Hartford, Conn., 30 March 1842; d. Gloucester, Mass., 4 July 1901. In 1855 he assumed the name of his maternal great-grandfather, John Fiske, of Middletown, Conn. In 1863 he was graduated from Harvard, in 1865 from the Harvard Law School, in 1864 was admitted to the Suffolk bar, but never entered legal practice. In 1861 he published in the 'National Quarterly Review' a notable critical article ('Mr. Buckle's Fallacies') on Buckle's 'History of Civilization in England.' From 1869 to 1879 he was at Harvard, first as a brilliant university lecturer in philosophy, and from 1872 as assistant librarian. In 1884 he received appointment to the chair of American history in Washington University (St. Louis, Mo.), where for some years he held annual lecture courses. His reputation as a lecturer was considerable, also, in Great Britain, where he delivered addresses on American history in 1879 at University College, London, and in 1880 at the Royal Institution. His earlier recognition, however, was chiefly as a thinker and writer in evolutionary philosophy, in particular as the foremost expounder to English-speaking students of Herbert Spencer's philosophic system. In this popularization of Spencer, best represented by his 'Outlines of Cosmic Philosophy' (1874), his lucidity won strong approbation from Darwin. From 1879 his attention was turned toward American history, largely through researches made by him in American aboriginal life in connection with a projected work on the Aryans. Thenceforth his philosophic studies took subordinate place, though he wrote in this field occasional volumes of much interest, and in his 'Idea of God' (1885) and 'Origin of Evil' gave ultimate presentation of his confirmed views on questions of philosophy and religion. In his series of historical writings, forming broadly a continuous account of events from the earliest discoveries to the beginnings of Federal government, he displayed a marked ability for clear and interesting narrative, and infused a particular interest into the adventurous characters and daring deeds of the period of exploration. He fails at times in points of minor accuracy, but in arrangement, judgment, proportion, and dramatic interest he exercised a strong influence on the progress of American historical studies in this country. His style here is not inferior to that of his philosophical treatises. He worked with tremendous energy, and, though dying prematurely, had accomplished an impressive amount of literary labor. Among the titles of his further volumes are: 'Myths and Mythmakers' (1872); 'The Unseen World' (1876); 'Darwinism and Other Essays' (1879; rev. ed. 1885); 'Excursions of an Evolutionist' (1883); 'The Destiny of Man' (1884); 'American Political Ideas' (1885); 'The Critical Period of American History' (1888); 'The War of Independence' (1889); 'The Beginnings of New England' (1889-98); 'Civil Government in the United States' (1890); 'The American Revolution' (1891); 'The Discovery of America' (1892); 'History of the United States for Schools' (1894); 'Edward Livingston Youmans' (1894); 'Old Virginia and Her Neighbors' (1897); 'The Dutch and Quaker Colonies in America' (1899); 'Through Nature to God' (1899); 'New France and New England' (1902); and 'Essays, Literary and Historical' (1902).

Fiske, Lewis Ransom, American Methodist minister and educator: b. Penfield, N. Y., 24 Dec. 1825. He was graduated at the University of Michigan 1850, entered the Methodist ministry, and held pastorates in Jackson, Ann Arbor, and Detroit. He taught in the State Normal School and the State Agricultural College of Michigan; was president of Albion College 1877–98; and has been professor emeritus of philosophy there from 1898. He was editor of the Michigan 'Christian Advocate' (1875–9). He has published: 'To-day and To-morrow' (1898); 'Chosing a Life-Work' (1900); 'Human Life and Its Forces' (1901).

Fiske, Stephen, American editor and author: b. New Brunswick, N. J., 22 Nov. 1840. He was graduated at Rutgers College and early became an editorial writer on the staff of the New York *Herald,* for which newspaper he acted as special correspondent in the suite of the Prince of Wales, now king of England, while the Prince was traveling in the United States and Canada, and later as war correspondent. For many years he was dramatic critic of the *Herald*; afterward managing the St. James Theatre and the Royal English Opera Company in London, and the Fifth Avenue Theatre, New York, presenting Modjeska and Mary Anderson. Among his works are: 'English Photographs'; 'Off-hand Portraits of Prominent New Yorkers'; and several plays including: 'Corporal Cartouche'; 'Martin Chuzzlewit'; 'My Noble Son-in-Law'; 'Robert Rabagas.'

Fission, fish'ŏn, a term in biology applied to various separation processes, as cell-division of the bacteria and related algæ, and the dividing of chromosonus (see EMBRYOLOGY). When used in reference to hydroids and related animals it means the process of reproduction by germination or budding, in which the offspring arises as a bud from the parent and is then constricted off. See BUDDING.

Fissirostres, fis-ĭ-ros'trēz, one of the four or five tribes or sub-orders into which the insessorial birds were divided by early ornithologists. The term is no longer used, as the group it represented was not a natural one. It contained the nightjars, swifts, trogons, and various other more or less related families.

Fissure, fish'ūr. Any rock fracture or crack is a fissure, but generally the term is applied to fractures of some size. If accompanied by dislocation of the rocks the fissure is termed a fault. The term true fissure vein so frequently used by miners should be applied to a vein formed along a fault. Such a vein is apt to have considerable length and sometimes great depth. As the term is commonly used by mine promoters it really means nothing except that the promoter wants to give the impression that the mine he is trying to sell is on a vein that will go down indefinitely. See FAULT; JOINT; ORE DEPOSITS.

Fissure. See BRAIN; RECTUM.

Fissure Needle, a spiral needle for drawing together the gaping lips of wounds. By revolution, the point is made to pierce the lips alternately, carrying its thread or silver wire with it. See SURGERY.

Fis'tula, a burrow or tract through the tissues. Usually the term is applied to tracts between cavities lined by mucous membrane or from a cavity to the body surface. The lining of the tract is infected with granulation tissues, which make it difficult to heal. They are formed by suppuration, or by a low grade of infection along the course of a false passage made by foreign bodies or surgical instruments. The most frequent sites are the anus, the rectum, the intestines, the bladder, the vagina, and the salivary ducts. Fistula in ano is always secondary to an abscess in the rectum or perirectal tissue. Abscesses here are difficult to heal, owing to constant inflection from the fæces and the construction of the parts. Chronic alcoholics, consumptives, and otherwise debilitated subjects are particularly liable to these abscesses, and consequently to fistulæ. When the passage is from the bowel to the skin, with openings at both points, it is said to be complete. Blind internal and blind external are two other common varieties. The tissues about the anus may be riddled with these tracts. The conversion of the tract into an open wound must be made before a positive cure will result.

Fistulina. See FUNGI.

Fitch, Ebenezer, D.D., American clergyman: b. Norwich, Conn., 26 Sept. 1756; d. West Bloomfield, N. Y., 21 March 1833. He was graduated at Yale College in 1777, where in 1780 he was appointed tutor, and continued to act as such for several years. In 1790 he was chosen preceptor of the academy in Williamstown, Mass., and when in 1793 it grew into and was incorporated as Williams College, he was elected its first president, which office he filled with ability and success till 1815, when, resigning, he was chosen pastor of the Presbyterian Church in West Bloomfield, N. Y. This charge he held till 1827.

Fitch, John, American inventor: b. East Windsor, Conn., 21 Jan. 1743; d. Bardstown, Ky., 2 July 1798. At the outbreak of the Revolution he became a gunsmith for the American troops, with whom he wintered at Valley Forge. He next made surveying and trading tours in the West, and after escaping from captivity among the Indians returned to Pennsylvania, where in 1785 he completed his first model of a steamboat: this had wheels at the sides, which were replaced in the following year with paddles or oars. In the face of discouragement and neglect he succeeded in constructing a vessel, 45 feet long and 12 feet beam, with an engine of 12-inch cylinder, which made a successful trial trip on the Delaware, at Philadelphia, 22 Aug. 1787. Larger vessels were built in 1788 and 1790, the latter being run as a passenger boat, at 8 miles an hour, to Burlington (20 miles) throughout the summer. Misfortune, however, dogged "poor John Fitch's" steps: his supporters fell away; and in 1793 he went to France to construct a steamboat, only to find his project frustrated by the Revolution there. It is said that his plans and specifications were deposited with the American consul at L'Orient, who for several months entrusted them to Robert Fulton (q.v.); and the latter's steamboat certainly was in 1817 declared by a committee of the New

York legislature to be "in substance the invention patented by John Fitch in 1791." Penniless and dejected, Fitch worked his passage back to America, where in the summer of 1798 he is said to have committed suicide at Bardstown, Ky. Consult Westcott, 'Life of John Fitch, Inventor of the Steamboat' (1857); Thurston, 'Growth of the Steam Engine' (1878).

Fitch, Sir **Joshua Girling,** English educationist: b. 1824; d. London August 1903. He was educated at the University of London. In 1852 he was appointed principal of the Normal College of the British and Foreign School Society and in 1877 government school inspector for the eastern counties. He was also examiner in English and member of the senate in the University of London. In 1888 he visited the United States with a view of studying transatlantic educational methods. The result of his observations he embodied in his 'Notes on American Schools and Colleges' (1890). Among his other works may be mentioned: 'Lectures on Teaching at Cambridge' (1881); 'The Arnolds and their Influence on English Education.'

Fitch, Ralph, English merchant and voyager of the 16th century. He dealt in eastern goods, and, excited by the narratives of Drake and other voyagers, persuaded John Newbery and others to join him in an expedition to the East by way of the Mediterranean. The adventurers set sail in January 1583, landed in Syria, went to Aleppo, and traversing Mesopotamia reached Bagdad. From that city they sailed down the Tigris and through the Persian Gulf to Ormus, where they began a profitable traffic. But their success roused the jealousy of other European merchants in those parts, one of whom denounced them as heretics to the Portuguese inquisition. The Englishmen were thrown into prison at Goa, but finally released, and seeing reason to apprehend further injustice, they secretly escaped. After passing through Golconda, they traveled north through the Deccan, and visited successively Burhampoor, Mandoo, Agra, Allahabad, Benares, Patna, Tanda in Bengal, and a country called by Fitch Couche, which appears to be at the foot of the mountains of Bootan. They traveled south to Hoogly and through Orissa, passing by a port called Angeli, which they described as the seat of a great trade. It cannot now be identified. Returning to the Ganges, they saw Serampore and other towns on its lower branches, made an excursion into Tipperah, and took passage in a vessel to Negrais, in Pegu. They visited Malacca, went back to Bengal, shipped for Ceylon, and thence doubling Cape Comorin sailed to Cochin and Goa, and returned to England in 1591, by the same route they had come, after having performed the most extensive journey that had yet been made by any Europeans in India. Fitch's narrative of his travels, which may be found in Hakluyt and in Purchas' 'Pilgrims,' is exceedingly interesting not less for its quaint style than for the mass of information which it contains.

Fitch, William Clyde, American playwright and author: b. New York 2 May 1865. He was graduated at Amherst College 1886. He has written many successful plays, among them: 'Beau Brummell'; 'The Climbers'; 'The Way of the World'; 'The Girl and the Judge'; 'Barbara Frietchie'; 'The Moth and the Flame'; 'The Stubbornness of Geraldine'; etc. He is also the author of: 'The Knighting of the Twins, and Ten Other Tales' (1891); 'Some Correspondence and Six Conversations' (1896); 'A Wave of Life,' a novel.

Fitch'burg, Mass., city, one of the county-seats of Worcester County, on the New York, N. H. & H., and the Fitchburg R.R.'s; 50 miles northwest of Boston. It comprises the villages of Traskville, Rockville, South Fitchburg, West Fitchburg, and Fitchburg Centre. It contains a public library, high school, electric street railroad, electric lights, several national and savings banks, and a number of daily and weekly newspapers. The various industries employ about 5,000 people. There are manufactories of pianofortes, tools, machinery, paper, saws, electrical apparatus, steam-engines, bicycles, firearms, cotton and woolen goods etc. Pop. (1900) 31,531.

Fitché, or **Fitchée,** fi-chā, in heraldry, pointed, like a dagger; sharpened at the lower part. Fitché is usually applied to crosses to indicate that they taper from the centre downward, or fitché at the foot, when the tapering commences only at the bottom of the cross. See Heraldry.

Fitchett, William Henry, Australian journalist and Methodist clergyman. He was educated at Melbourne University, entered the Methodist ministry and for a time edited the Melbourne *Daily Telegraph.* He is the editor of the 'Review of Reviews' of Australia, and principal of the Methodist Ladies' College at Melbourne. He has published: 'Deeds that Won the Empire' (1897); 'Fights for the Flag' (1898); 'Stories of the Indian Mutiny'; 'How England Saved Europe' (1899); 'Wellington's Men' (1901); 'Nelson and His Captives' (1902).

Fitchew. See Polecat.

Fitger, Arthur Heinrich Wilhelm, hīn'rīн vil'helm fit'gėr, German poet and painter: b. Delmenhorst, Oldenburg, 4 Oct. 1840. He has written several successful dramas: 'Adalbert of Bremen' (1873), with the afterpiece 'Here Empire! Here Rome!' (1875); 'The Witch' (1878); 'The Roses of Tyburn' (1888). Besides these he is the author of a short epic, 'Roland and the Rose' (1871); and two volumes of collected poems, 'Traveling Folks' (1875), and 'Winter Nights' (1881). He has painted several important friezes and other decorations at Bremen and Hamburg.

Fitts, James Franklin, American journalist and novelist: b. Lockport, N. Y., 1840; d. there 11 Jan. 1890. During the Civil War he distinguished himself on several occasions, and was rewarded with promotions. After the war he devoted himself to writing for newspapers, magazines, and syndicates. Of his novels the most popular were: 'The Parted Veil'; 'A Version'; 'A Modern Miracle'; 'Captain Kidd's Gold.'

Fitz (old French for *fils*, son), a syllable frequently forming a prefix in English surnames (Fitz-Herbert, Fitz-Clarence, Fitz-James), like the Scottish Mac, and the Irish O'. Latterly *Fitz* usually denotes illegitimate descent. There are several noble families of such origin, who include their royal progenitors in their genealogical tables.

Fitzball′, Edward, English dramatist: b. Burwell, Cambridgeshire, 1792; d. 1873. His name was orginally Ball, but he substituted the present form in 1819. He made his first dramatic success with 'The Innkeeper of Abbeville' (1820). This was succeeded by a dramatization of 'The Fortunes of Nigel' (1822); and 'Joan of Arc,' and he soon became a prolific dramatist, turning out plays to order in great number, and some of them having enormous success. Among his works are: adaptations of Scott's 'Peveril of the Peak' and 'Waverley' (1823); 'The Pilot' (200 nights); 'The Flying Dutchman' (1828); 'Jonathan Bradford' (1838) (400 nights); 'Walter Tyrrell' (1835); 'Zazezizozu' (1836); 'The Momentous Question'; 'The Miller of Derwentwater'; and libretti for several of Balfe's, Donizetti's, Bishop's and Wallace's operas. He was the author of 'Thirty-five years of a Dramatic Author's Life.'

Fitzgerald, fits-jĕr′ald, **Edward,** Lord, Irish patriot: b. near Dublin, Ireland, 15 Oct. 1763; d. 4 June 1798. He was a son of the first Duke of Leinster. He distinguished himself for intrepidity as aide-de-camp to Lord Rawdon in the American Revolution, and was severely wounded in the battle of Eutaw Springs. When the French Revolution broke out, he supported its principles, and in 1793 hastened to Paris. Here he married Pamela, the reputed daughter, it is said, of Louis Philippe Joseph, the Duke of Orleans, and Madame de Genlis. On his return to Ireland, Fitzgerald was desirous of effecting a separation of that country from England, and induced the French Directory to furnish him with a fleet and troops. A landing was attempted on several occasions, but without success, and Fitzgerald was seized, tried, and condemned to death. He died of his wounds before the time fixed for his execution, 1798. His wife married a second time, Mr. Pitcairn, the American consul at Hamburg, from whom, however, she separated soon afterward. See Moore, 'Life and Death of Edward Fitzgerald' (2d ed. 1875).

Fitzgerald, Edward, English poet: b. near Woodbridge, Suffolk, 31 March 1809; d. Merton, Norfolk, 14 June 1883. At 17 he entered Trinity College, Cambridge, where he graduated in 1830. At school and college he formed several lifelong friendships with men who afterward became celebrated in different spheres, among them being Spedding and Thackeray. At a later period he gained the friendship of Tennyson and Carlyle. His life was passed quietly — almost in retirement — in various parts of Suffolk, first at Bredfield, his birthplace, then near Ipswich, where he contracted friendships with George Crabbe, the son of his favorite English poet, and Bernard Barton, the Quaker poet; and lastly at Boulge Hall and Woodbridge. Books were his chief indoor recreation; out of doors he occupied himself at first chiefly with boating, and afterward with his garden. Fitzgerald's works are not numerous, by far the most important being his celebrated translation of the 'Rubaiyát' (or quatrains) of the Persian semi-pessimistic astronomer-poet, Omar Khayyám. Having for some time studied Persian, in 1856 he published a translation of Jámi's 'Salámán and Absál.' Three years later his *magnum opus* appeared without causing any stir, but before he died four editions had been issued. The beauty of Fitzgerald's poem is universally admitted, but some have doubted whether it does not contain more of the Englishman than of the Persian. The general consensus of opinion now seems to be that though undoubtedly embellished, altered in some ways and adapted, we have in Fitzgerald's work a real translation of Khayyám's. Other works by him are: 'Euphranor: a Dialogue on Youth' (1851); 'Polonius: a Collection of Wise Saws and Modern Instances' (1852), both of which appeared anonymously; 'Six Dramas of Calderon, freely translated by Edward Fitzgerald' (1853); and translations of Æschylus' 'Agamemnon' and the 'Œdipus' plays of Sophocles. Tennyson's poem, 'Tiresias,' was dedicated to Fitzgerald. See 'Letters and Literary Remains of Edward Fitzgerald,' edited by W. Aldis Wright (1889; new edition 1894); 'Variorum Edition of the Poetical and Prose Writings of Fitzgerald,' edited by Bentham (1902–3).

Fitzgerald, James Newbury, American Methodist bishop: b. Newark, N. J., 27 July 1837; d. Hong Kong, China, 3 April 1907. He studied law and was admitted to the New Jersey bar in 1858, but in 1862 entered the Methodist ministry. He was recording secretary of the missionary society of his denomination 1880–8, and was appointed bishop in 1888.

Fitzgerald, Oscar Penn, American Methodist bishop: b. Caswell County, N. C., 24 Aug. 1829. He was ordained a Methodist minister in Georgia 1853, went to California 1855 and became editor of the 'Pacific Methodist and Christian Spectator,' serving as State superintendent of public instruction in California 1867–71, and being appointed editor of the Nashville 'Christian Advocate' 1878. He was made a bishop of the Methodist Episcopal Church, South, 1878. His works include: 'California Sketches'; 'Christian Growth'; 'Glimpses of Truth'; 'A Life Study'; 'Centenary Cameos'; 'Bible Nights'; 'Eminent Methodists'; 'The Whetstone'; 'The Epworth Book'; 'The Menagerie'; 'Judge Longstreet'; 'Sunset Views' (1900); 'The Day and the Word' (1898); etc.

Fitzgerald, Percy Hetherington, Irish novelist and miscellaneous writer: b. Fane Valley, south Ireland, 1834. Educated at Trinity College, Dublin, he was called to the Irish bar in 1855, and was afterward a crown prosecutor on the northeastern circuit. Beside novels he has written many biographical and other works, of which the most important are: 'Life of Laurence Sterne' (1864); 'Charles Lamb: His Friends, His Haunts, and His Books' (1865); 'Charles Townshend, Wit and Statesman' (1866); 'Life of David Garrick' (1868); 'Principles of Comedy and Dramatic Effect' (1870); 'The Kembles: an Account of the Kemble Family' (1871); 'Book of Theatrical Anecdotes' (1873); 'The Romance of the English Stage' (1874); 'Life, Letters, and Writings of Charles Lamb' (1875–6); 'History of the Suez Canal' (1876); 'Croker's Boswell, and Boswell: Studies in the Life of Johnson' (1880); 'A New History of the English Stage' (1882); 'The Royal Dukes and Princesses of the Family of George III.' (1882); 'Kings and Queens of an Hour: Records of Love, Romance, Oddity, and Adventure' (1883); 'Life and Times of

William IV.' (1884); 'The Lives of the Sheridans' (1887); 'Life and Times of John Wilkes, M.P.' (1888); 'Picturesque London' (1890); 'Henry Irving: a Record of Twenty Years at the Lyceum' (1893); 'Fifty Years of Catholic Life and Social Progress' (1901).

Fitz-Gerald, Shafto Justin Adair, English novelist and dramatist: b. 9 Nov. 1859. He has published: 'Sketches from Bohemia' (1890); 'The Wonders of the Secret Cavern' (1892); 'Ballads of a Bohemian' (1893); 'A Book of Words' (1895); 'The Mighty Toltec' (1897); 'Stories of Famous Songs' (1897); 'The Grand Panjandrum' (1898); 'The Black Tulip' (1899); 'Rip Van Winkle' (1900); 'How to Make Up' (1901); and a dozen or more plays.

Fitzgib'bon, Mary Irene, American philanthropist: b. London, England, 12 May 1823; d. New York 14 Aug. 1896. She removed to New York early in life; entered the community of the Sisters of Charity at Mount St. Vincent in January 1850, and became sister superior in 1856. In 1869 Archbishop (later Cardinal) McCloskey requested her to organize a work for the care of the waifs of the diocese. On 11 Oct. 1870 the New York Foundling Asylum was opened and within a month was caring for 45 children. During the same year the legislature authorized the city to grant the asylum a site and to appropriate $100,000 toward a building, providing an equal amount should be provided by subscriptions. This amount was soon raised. At the time of Sister Irene's death, the buildings of the asylum covered an entire block and were valued at over $1,000,000. Aside from having full charge of this institution from its inception, Sister Irene raised $350,000 with which she founded the Seton Hospital for Incurables.

Fitzher'bert, Maria Anne (Smythe), morganatic wife of King George IV. of England: b. Brambridge, England, 26 July 1756; d. Brighton, England, 27 March 1837. Her first husband was Edward Weld, to whom she was married in 1775. He died within a year and she was married to Thomas Fitzherbert 1778. He died in 1781 and she was married to the Prince of Wales 21 Dec. 1785. Under the Marriage Act of 1772 the marriage might have been declared invalid if publicly acknowledged, and it would, if avowed, have changed the succession under the Act of Settlement, Mrs. Fitzherbert being a Catholic. She, however, lived with the prince as his wife, the relationship ending in 1803.

Fitzhugh', George, American lawyer: b. Prince William County, Va., 2 July 1802; d. Huntsville, Texas, 30 July 1881. He held very extreme views in reference to slavery. He published: 'Sociology for the South, or the Failure of Free Society' (1854); 'Cannibals All, or Slaves Without Masters' (1856).

Fitz-John Porter Case, The. See PORTER, FITZ-JOHN.

Fitzmaurice, fits-mor'ris, LORD **Edmond George,** English politician: b. 19 June 1846. He sat in the House of Commons for Calne 1869–85, and was under-secretary for foreign affairs 1882–5. He has published: 'Life of William, Earl of Shelburne' (1875–7); 'Sir William Petty, the Political Economist' (1895).

Fitzmaurice-Kelly, James, English scholar: b. 20 June 1858. He was examiner in Spanish at Oxford University 1900–2, and has published: 'The Life of Miguel de Cervantes Saavedra' (1892); 'History of Spanish Literature' (1898); and edited the complete works of Cervantes.

Fitzpat'rick, Benjamin, American politician: b. Green County, Ga., 20 June 1802; d. 1869. He settled in Alabama in early life, studied law, and in 1821 obtained license to practise. He was soon afterward elected State's attorney, and held that office until 1829. In 1841 he was elected governor, and in 1843 was re-elected without opposition. In 1848 he was appointed United States senator to fill a vacancy, and continued in the Senate until 1861.

Fitzpatrick, Charles, Canadian lawyer and politician: b. Quebec 19 Dec. 1853. He was graduated at Laval University in 1873 and being admitted to the bar in 1876, was appointed crown prosecutor for the city and district of Quebec 1879 and 1887. He was a member of the Quebec Assembly 1890–6, and was elected to the Dominion Parliament 1896, becoming solicitor-general in the same year.

Fitzralph', Richard, English prelate: b. Dundalk, Ireland, about 1300; d. Avignon 16 Nov. 1360. He took orders, becoming Fellow of Balliol College, Oxford, and being made chancellor 1333. He was archbishop of Armagh 1347. He was a popular preacher and in favor with the Pope at Avignon, interesting himself greatly in the Armenian question, and also in the case of the secular clergy against the mendicant friars in England. In connection with the former he wrote an argument, 'Summa in Questionibus Armeniorum,' and in reference to the latter a treatise 'De Pauperie Salvatoris.' When summoned by the friars before Pope Innocent VI. he defended himself in a notable sermon, 'Defensio Curatorum,' dying before the case was decided. His bones were taken to Dundalk 1370, where his tomb became an object of veneration.

Fitzroy' River, the name of two Australian rivers, one in western Australia and one in Queensland. The former rises in the King Leopold Mountains and empties in King Sound; length 300 miles. The Queensland River is formed by the junction of the Mackenzie and the Dawson and empties into Keppel Bay.

Fiume, fē-oo'mĕ, Austria-Hungary, seaport town on the small river Fiumara; 40 miles southeast of Trieste. Some of the manufactures include tobacco, paper, leather, chemicals, soap, torpedoes, and rosoglio, and it carries on shipbuilding. Since 1872 the Hungarian government has spent large sums in providing moles, quays, docks, and other accommodations, with the result of immensely increasing the trade. The principal exports are corn, sugar, tobacco, wood, fruit, refined petroleum, etc.; the principal imports — wine, coal, jute, rice, cotton, salt, etc. Pop. 29,494.

Five or Nine, a game, analogous to dominoes, played with a pack of 52 cards. The name is derived from the fact that the player leading off to the table must play a five or a nine; then the cards are played in sequence, as dominoes are placed. The rules of the game are similar to those governing dominoes. The game is also called domino whist. See DOMINOES.

Five-cent Piece, Half-dime, or **"Nickel."** Silver half-dimes were the first coins struck under the Coinage Act of 1792. None were coined in 1798, 1799, 1804, or 1806 to 1828. See COINS; NUMISMATICS.

Five-fingers. A starfish (q.v.).

Five Forks, Battle of. At the close of the battle of Dinwiddie Court House, 31 March 1865, Gen. Sheridan was holding position in front of the place, Gen. Pickett, with infantry and cavalry, confronting him. At 12 P.M. Pickett, threatened by Warren's Fifth corps on his left, ordered a retreat to Five Forks to protect his communications with the South Side Railroad. Sheridan followed him at daylight with Devin's and Custer's divisions, Crook's division being thrown on roads to the left. Pickett was found entrenched at Five Forks. By 1 P.M. Sheridan's cavalry had worked close up to Pickett's lines, and Sheridan ordered up the Fifth corps. MacKenzie's cavalry division, advancing on the extreme right, drove back Robert's cavalry and gained the White Oak road.

At 4 P.M. Warren had formed his lines, Ayres' and Crawford's divisions in double lines, with one brigade in reserve, on the left and right respectively of the Gravelly Run Church road. A few moments brought Warren to the White Oak road, and Ayres, whose right had crossed it, received a severe fire upon his left, and at once changed front and attacked the return of the entrenchments. Crawford kept straight on through the woods and, receiving fire from Munford's cavalry, swerved to the right, thus isolating his division from Ayres, and Griffin followed Crawford. But Griffin and his brigade commanders taking in the situation, soon marched by the left flank and protected Ayres' flank, which had been thrown into some confusion. Ayres meanwhile, connecting with the cavalry on his left, had made a gallant charge, carried the left of the Confederate works and, with support on the left and right, swept down inside them to and beyond Five Forks, capturing many prisoners. The only stand the Confederates tried to make was on the road leading to the railroad, and at this point they were pressed so closely by Griffin and Crawford that they soon gave way. On the right Warren took Crawford's division in hand, changed its direction to the left and, advancing in rear of the Confederate infantry line, with MacKenzie's cavalry on the right, drove Munford's cavalry, continually turning the left of the Confederates opposing Ayres and Griffin, gained the road leading to the South Side Railroad, forced Munford north of Hatcher's Run, and took four guns and many prisoners. On the extreme left Custer had a severe fight with cavalry and infantry, and gained but little ground until Devin and Ayres, advancing behind the works, drove the infantry out. The Confederate cavalry made no further stand, save to cover the retreat, and just before dark Custer, in connection with an attack by a small body of the Fifth corps, led by Warren in person, drove the last of the Confederates westward on the White Oak road, and followed them until long after dark. The battle was one of the most decisive of the War. The Confederates were totally routed, losing over 5,000 men captured, 6 guns, and 11 colors. The Union loss was 830 killed and wounded, of which the Fifth corps lost 634. The Confederate loss in killed and wounded is not definitely known. Consult: 'Official Records,' Vol. XLVI.; Humphreys, 'The Virginia Campaign of 1864–5'; Powell, 'The Fifth Army Corps'; Sheridan, 'Personal Memoirs,' Vol. II; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. CARMAN.

Five Members, The, whom Charles I. attempted to arrest early in 1642, were John Pym, John Hampden, Denzil Holles, Sir Arthur Haselrig, and William Strode, representing in the Commons Tavistock, Buckinghamshire, Dorchester, Leicestershire, and Dorchester respectively. The king, expecting an impeachment of the queen, determined to prevent it by impeaching these commoners along with Lord Kimbolton. The impeachment was subsequently abandoned when the Commons had declared against the illegality of his procedure. See ENGLAND.

Five-mile Act, an old English law, passed in 1665, which forbade non-conformist pastors who refused to take an oath of non-resistance to come within five miles of any corporation in which they had preached since the passing of the Act of Oblivion in 1660. The law was repealed in 1688.

Five Nations, a confederacy consisting of five tribes of Indians who lived in the western and central part of what is now the State of New York. The five tribes were: the Cayugas, Mohawks, Oneidas, Onondagas, and Senecas. In 1712 the Tuscaroras were taken into the confederacy, and they were then known as the Iroquois, or the Six Nations. See IROQUOIS, OR THE SIX NATIONS.

Five Points, New York, a locality between Centre and Reade streets and Park Row. At one time it was noted as a resort for criminals and "hard cases." The Ladies' Home Missionary Society of the Methodist Episcopal Church began a reform work at Five Points in 1850, and they have been most successful. The Church of the Ascension contributed funds to establish an industrial school which, in 1854, was incorporated. The mission secured by purchase and by building an excellent home, which they still occupy; and thousands of children have been reclaimed and educated through the efforts of the mission workers. The character of the place has changed greatly for the better.

Five Points of Doctrine, the principal subjects of doctrine which are disputed topics between Arminians and Calvinists. They are: (1) extent of the atonement; (2) predestination; (3) free will; (4) grace; (5) final perseverance. Various efforts have been made to settle the differences; they were fully discussed at the Synod of Dort, in Holland, in 1618–19; at Cambridge, in England, in 1594, and at two other conferences held in England in 1626.

Five-twenties (that is, redeemable after 5 years and payable in 20), 6 per cent gold bonds issued in 1862, 1864, and 1865. See DEBT, UNITED STATES.

Fives, an English game, originally called hand-tennis, in which the ball is struck against a wall. It is played either in close or in open courts, of various shapes and proportions. The game is known as hand-fives or bat-fives, according as the ball is struck by the open hand or a small wooden bat. The origin of the name is disputed. Also a disease in horses, resembling the staggers, and consisting of an inflammation of the parotid glands; written also vives.

Fixed Oils, in medicine, oils used as demulcents, laxatives, and in external application as emollients. Some, notably linseed oil, while still in the seed, are very useful in poultices because of the high specific heat of the oils. By means of this specific heat the poultice stays warm much longer. Others of the fixed oils are useful as foods — cod-liver oil, peanut oil, etc.

Fixing. (1) In machinery, a piece of cast iron adapted to carry pillow blocks and the like. When it is built into a wall it is called a wall fixing, or wall box; when attached to a wall by bolts it is a plate fixing. There are also beam fixings, as when wheels intended to work at the position where the fixing is situated; and when the fixing is adapted to them, it is then commonly called a wheel fixing. (2) In metallurgy, the material used in preparing the hearth of a puddling or boiling furnace for receiving its charge. It is called fettling in some parts of England. (3) In photography, of a negative; the removal, by a solution of hyposulphite of soda or cyanide of potassium, of the unaffected deposit of iodide and bromide of silver in the collodion film after exposure and development of the picture. Of a positive; the removal of the unaltered chloride of silver from the surface of the photographic paper after exposure under the negative.

Fjord. See Fiord.

Flabellum. See Fans.

Flaccus, Caius Valerius, kā'yus va-lē'rĭ-us flak'us, Roman poet of the latter half of the 1st century. He lived in Padua, and died young. He sung the expedition of the Argonauts in an epic poem, ‘Argonautica,’ of which seven books and part of the eighth have remained to us.

Flacius, flā'shĭ-us, or **Vlacich, Matthias,** mät-tē'äs flä'siH, German Lutheran theologian: b. Albona, Illyria, 1520; d. Frankfort-on-Main 1575. He became professor of the Hebrew Scriptures at Wittenberg University in 1544. From this time he took an active part in all the theological discussions of the time; and for his attacks on Melanchthon's compromise, known as the Leipsic Interim, he was, four years later, deprived of his professorship. Nor did he procure another appointment until 1557, when he became professor of theology at Jena. This post he again lost, after five years, on account of his doctrine that original sin was essentially inherent in man's nature. Of his numerous works three deserve mention: ‘Clavis Scripturæ Sacræ’ (1567); ‘Catalogus Testium Veritatis’ (1556); ‘Ecclesiastica Historia’ (1559–74).

Flag, a strip of cloth of a light fabric, varying in form and color, frequently bearing some emblematic design, and ordinarily fixed by one end to a staff, pole, rope, etc., while the other is allowed to fly free. The length of a flag from the part near the staff to the free end is called the fly, and the measurement at right angles to this is known as the hoist, height, or depth.

The uses of flags are numerous. They serve in a variety of ways as signals. They convey definite information of various kinds, and are used as general symbols of rejoicing, congratulation, sympathy, mourning, etc. In a classification of the uses of flags, that which stands first, as the most general, is their use as national emblems. Next in order comes their use as distinguishing emblems of the naval and military forces of particular nations. In the army each regiment is distinguished by its particular flag or colors. This usage is general, and the colors of regiments come to be distinctive of their services and of their *esprit de corps,* as well as of their position in the army. Flags are sometimes presented by persons of rank or official station, or by other individuals or groups of people, and often bear names and emblems commemorative of past achievements. In Catholic countries their consecration is a religious ceremony. This use of flags is of great antiquity. In the Bible the standards of the different tribes are referred to in the arrangement of the camp of the Israelites in the desert. The Greek and Roman armies had their distinctive flags. In the French army distinctive flags were introduced during the wars in Italy in the 16th century. The word *drapeau* in French (which, in its most extended signification is equivalent to our "flag") is used specifically for the colors of an infantry regiment; *étendard* for those of a cavalry regiment; *pavillon* for the colors used in the naval service.

The union of St. Andrew and St. Patrick marks, first the union of England and Scotland into the kingdom of Great Britain and then this kingdom with Ireland. This is the union flag of Great Britain, and was brought by the colonists to America. (See Flag, The American.) Every battalion of infantry in the British army, except the Rifles, has two colors; namely, the king's color and the regimental color. The former consists, for all regiments, of the union device, with the name of the regiment in the centre and the number of the battalion on the upper part near the staff. The regimental color is of the same color as the collars and facings of the regiment; but if these are white, it bears a St. George's cross in red. On it are emblazoned the name of the regiment, the names of the battles in which it has served, and its various badges, crests, mottoes, etc. Among cavalry regiments, only the guards, dragoon guards, and dragoons have standards, as cavalry flags are termed. These are made of crimson silk, and are emblazoned like those of infantry regiments. The standards of the guards and dragoon guards are rectangular, like those of the infantry, but the dragoons carry standards with the end farthest from the staff rounded and scalloped. The lancers have red and white pennants on their lances.

The standard is the war-flag, and bears the royal or other arms of the nation. Ensigns are flags carried by ships to indicate their nationality. The place for the ensign in a steamer or large ship is on a pole over the taffrail; in schooners and similar ships, at the peak of the main gaff; in cutters and sloops, at the peak; in yawls, at the mizzen-peak; and in rowing-boats, over the stern.

Jacks are national flags used for signaling and various other purposes. Pennants or pendants are small pointed or swallow-tailed flags generally used in connection with signals. The best-known is the answering pennant used in the international signal-code. A burgee is a swallow-tailed flag used by yachts and merchant vessels, usually with the ship's name on it. Shipping companies generally have square flags with distinctive colors and devices; these are known as house-flags. A plain white flag indicates a clean bill of health, and is also used in war as the flag of truce (q.v.). The quarantine flag is yellow. Vessels carrying explosives display a red flag. A flag hoisted upside down is a signal of distress, and one borne half-mast high is a sign of mourning. Flags are often dipped in token of respect. See SIGNAL SERVICE.

Flag, The American. The colonies used the English flag, bearing first the red cross of St. George; after the union with Scotland in 1707, the "union" of St. George and St. Andrew; the present union jack, with St. Patrick's added, dates only from 1801. It was the former which Endicott cut from the flag as a popish symbol; Massachusetts petitioned for red and white roses in their place, but the military commissioners simply left out the cross and substituted the king's arms. Militia companies had sometimes their own flags. In 1686 Andros had a special one made for the New England Union. From 1700 to 1750 the New England flags were "a red or blue ensign cantoned white, with a red St. George's cross, and having a tree or globe in upper corner of the canton" (Preble); the tree is usually assumed as a pine, like that on the coins, but in neither case with any evidence. The colonial merchant ships, to distinguish them from the mother country's, had a white escutcheon in the middle of the jack. The first outbreak of special flags was at the time of the Stamp Act, when each gathering usually improvised a flag. But the "union flags" of the early Revolution times and just before seem to have been the English union jack with patriotic mottoes: the colonies kept up the theory that they were loyal subjects of England. What flag or flags, if any, were used at Bunker Hill is uncertain, as the British captured none, and the reminiscences are inconsistent. Most probably each detachment had its own and carried it off.

In the early part of the Revolutionary War there was no attempt at a national flag, each colony or even troop or privateer pleasing itself. Some of the famous ones — as Col. William Washington's at Eutaw Springs, a piece of crimson damask cut by his fiancée from her upholstered chair — were private. The public ones were mainly of two sorts. The New England type had a tree (officially made a pine) in green on a white ground, and "An Appeal to Heaven" or the Connecticut "Qui Transtulit Sustinet" as a legend; in one case, a pine and a field of Indian corn, with two wounded officers and several children, and the motto, "For posterity we bleed." One of greater national significance was the rattlesnake type: at first cut into 13 pieces, with the initial of a colony on each, and the legend "Join, or Die"; then coiled to strike, with the legend "Don't Tread on Me"; later, 13 stripes with the snake across them. In either case, there were generally 13 rattles. Another flag was white, with a mailed hand grasping 13 arrows; still another, a female figure with a staff from which streamed 13 pennants. The first in the South was said to be devised by Col. Moultrie, in the fall of 1775 — a large blue flag with a crescent in the right upper corner, and "Liberty" in the centre; this was the one used in the defense of Fort Moultrie, and which Sergt. Jasper picked up under the British fire.

The national flag had no single or definite origin. After a few months of war it was seen to be needful, but the reluctance to break with the English pattern confirms the sincerity of the protestations of continued loyalty; and in December 1775 a committee consisting of Franklin, Thomas Lynch, and Benjamin Harrison recommended, and Congress adopted, the British union plus 13 stripes, which was hoisted over the headquarters at Cambridge, 1 or 2 Jan. 1776. The origin of the stripes is so utterly unagreed that it is probable any one of several things may have suggested it: their use on the Dutch East India Company's flags; those on the escutcheon of the Washington family; or simply the stripe which was the one distinguishing feature of the army uniform. Paul Jones claims to have been the first to raise the national flag, late in December 1775, but it seems to have been one of the rattlesnake type; that, however, was the kind selected by the Congressional naval committee on 8 Feb. 1776. In June 1776 it was unofficially decided by Congress and Washington, in view of the impending Declaration, to replace the union by a five-pointed star; but the first official adoption of a flag was on 14 June 1777, displacing the union by 13 stars, "a new constellation," and using just 13 stripes. The first use of the new flag is disputed; it seems to have been improvised and run up over captured British standards at Fort Stanwix, 8 Aug. 1777, after the battle of Oriskany, but a regular flag was made and carried at the battle of Brandywine, 11 September. Historical paintings are full of anachronisms as to flags. The stars were generally in a circle. The first change was the addition of two new stripes and two new stars for Vermont and Kentucky, in 1794; and though Ohio and Louisiana came in, no further alteration was made for nearly a quarter of a century. The stars were generally in three lines of fives. Finally, on 4 April 1818 it was ordered that the 15 stripes be reduced permanently to 13, in memory of the original colonies, and the stars keep pace with the total number of States, on the 4th of July after each admission. The arrangement of the stars was not specified, and has been at the taste of the makers. The revenue flag has 13 blue stars on a white ground, as a union, with 16 perpendicular red and white stripes; it indicates the authority of the Treasury Department. The secretary of war, the secretary of the navy, and the President have each their flags; the latter carried at the main of naval vessels and on boats he is in. Each of the flag-officers has his own flag. The union jack, white stars on a blue ground, is used by pilots, and at the bow of ambassadors' and ministers' boats.

The Confederate States had their own flags. But at the outset of the War their Congress adopted the "Stars and Bars"— having a white stripe between two red ones, and a blue union with seven white stars in a circle, for the number of seceding States. Later the stars were increased to 13. The usual battle-flag was red, with a blue cross and white stars diagonally. Late in the War the "bars" were exchanged for a white ground next the staff and red outside; and it was sometimes made black. Consult: Preble, 'History of the Flag' (1872).

Flag Association, The American, an organization formed in the council chamber of the city hall, New York, 12 Feb. 1898, with the object of honoring the national flag and of protecting it from desecration by securing the enforcement of present laws and the enactment of others for that purpose. The association was an outcome of the Congress of National Patriotic Societies held at the same place in November 1897, and besides individual members it is composed of the members of these societies, many of which are actively represented in the association by their flag committees. In order to promote respect and love for the flag, the association encourages its proper display on private buildings, schoolhouses, churches, etc., and uses its influence to make the observance of Flag Day (June 14) a national custom.

Flag, Sweet, an aquatic, flag-like plant (*Acorus calamus*) of the natural order *Acoraceæ,* which grows in wet places throughout the northern hemisphere, and is well known for its sweetly odorous leaves and root. The leaves are sword-shaped, 3 to 6 feet long, and the spadix is lateral with bisexual flowers. The creeping, woody rhizome has long been employed in medicine as an aromatic stimulant, considered useful in ague in Great Britain, and in India as a remedy for intestinal ills among children. It is also employed in flavoring beer, and by makers of snuff and vinegar; and is chewed by singers to clear the voice.

Flag of Truce, a white flag displayed in time of war as an indication of a desire to communicate with the enemy. The flag of truce is regarded as of so sacred a character that to shoot the bearer intentionally and without warning is to place the stigma of disgrace upon the side perpetrating the act. The display of a flag of truce during active hostilities does not necessitate the cessation of firing, and accidental shooting of the bearer may be unavoidable. If he advances during an engagement, he may be denied permission to enter the enemy's lines, or he may be held. To take advantage of the protection of a flag of truce in an illegitimate way, as for instance in order to obtain information of the enemy's resources, is held to be peculiarly dishonorable. A flag of truce is not regular unless sent and received by order of the senior officers of the respective forces. During naval hostilities, a flag of truce is met by a boat in charge of a commissioned officer from the senior officer's ship.

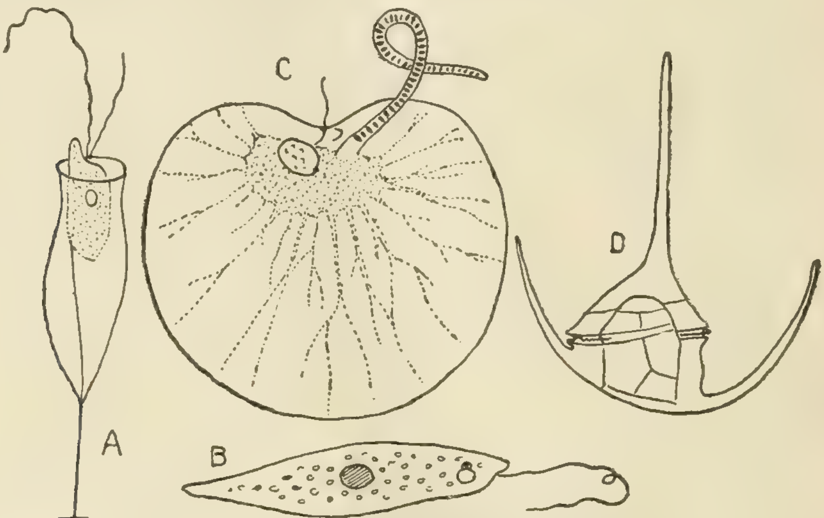
Flagellants, flaj'e-lants (Lat. *flagellare,* to lash or scourge), a sect which arose in 1260 at Perugia, called by the French *Perouse,* and spread throughout and beyond Italy. Its adherents, said to have numbered 10,000, attempted to expiate their sins and obtain mercy by self-inflicted suffering. They ran through the cities scourging their bare shoulders and exhorting bystanders to repentance. Led by priests bearing banners and crosses, they moved in procession through the streets. They could be seen going about by night as well as by day, even in the cold of winter. They went in thousands from country to country begging alms. In 1261 they crossed the Alps in Alsatia, Bavaria, Bohemia, and Poland, and found there many imitators. In 1296 a small band of Flagellants appeared in Strasburg, who, with covered faces, whipped themselves through the city, and at every church. At first the Flagellants were noted for sanctity, and made many converts even from the most abandoned classes, but doubtful characters beginning to join their ranks, they fell into disrepute, and were restrained from their processions by the civil and ecclesiastical authorities, then the sect gradually died away. The terror produced by the dreadful disease called the black death, which destroyed many millions of people in Europe in the middle of the 14th century, produced a revival of the flagellation mania, which spread over most of Europe and was attended by greater extravagances than before. In the reign of Edward III., a band of 120 Flagellants, male and female, made their appearance in London on a missionary enterprise, but had to leave the country without having made one proselyte. In 1349 Clement VII. declared the Flagellants heretics and took steps to repress them. In 1414 an effort was made in Thuringia to revive them, under a form marked by wild fanaticism and by strange doctrines which were condemned by the Council of Constance. The burning alive of their leader, Conrad Schmidt, and 90 of his followers, partially checked the project, though the extirpation of the sect was found a work of extreme difficulty. One form of fanaticism which marked some of the Flagellants was violent hatred and persecution of Jews.

Flagellata, a group of *Protozoa,* sometimes regarded as a division of the class Infusoria, sometimes as a distinct class by itself. The group is characterized by having a body-form usually fixed and definite for the species, and by having as organs for locomotion and taking of food one or more long vibratile whiplash-like processes, the "flagella." Like all Protozoa (q.v.) the body is composed of a single cell. The group is divided into three orders: *Autoflagellata, Dinoflagellata* and *Cystoflagellata.* In the Autoflagellata the body is usually oval and has both nucleus and contractile vacuole. Sometimes the body is naked and capable of amœboid motions, but usually it has a cuticle and enveloping cases are not uncommon. In one sub-order (*Choanoflagellata*) a peculiar collar-like structure is developed around the flagellum. Some of the group closely approximate plants, some forms like Euglena and Volvox being claimed by the botanist. A few are human parasites. The Dinoflagellata have a firm external armor of hard cellulose plates, divided by a groove around the body, and with a second longitudinal groove. At the junction of the two grooves are the two flagella, one lying in the circular groove, the other projecting freely. These forms occur in salt and fresh water. In the Cystoflagellata the large gelatinous body is enclosed in a stout membrane. The best-known form is Noctiluca (q.v.), noted for its phosphorescent powers.

Flagella'tion, scourging or whipping, either self-inflicted or administered by another person, especially as a religious practice. Its application as a means of religious penance is an old Oriental custom, admitted into Christianity partly because self-torment was considered salutary as mortifying the flesh, and partly because both Christ and the apostles underwent scourging. From the 1st century of Christianity religious persons sought to atone for their sins by voluntary bodily torture. Like the Abbot

Regino, at Prum, in the 10th century, many tried to imitate the sufferings of Christ, in order to make themselves the more certain of forgiveness through him. It became general in the 11th century, when Peter Damiani of Ravenna, abbot of the Benedictine monastery of Santa Croce d'Avellano, near Gubbio, in Italy, afterward cardinal bishop of Ostia, zealously recommended scourging as an atonement for sin, to Christians generally, and, in particular, to the monks. His own example and the fame of his sanctity rendered his exhortations effective. Clergy and laity, men and women, began to torture themselves with rods, and thongs, and chains. They fixed certain times for the infliction of this discipline upon themselves. Princes caused themselves to be scourged naked by their father confessors. Louis IX. constantly carried with him for this purpose an ivory box, containing five small iron chains, and exhorted his father confessor to scourge him with severity. He likewise gave similar boxes to the princes and tomb of Thomas à Becket (q.v.). In its theological aspect flagellation has no especial merit in itself and is classed merely as a form of penance or self-mortification. It is meritorious only as a means of expiation of sins repented for and absolved, or as a method of mortification of the flesh for the suppression and control of the passions. Any excess in it is prohibited. See FLOGGING; PENANCE; WHIPPING POST.

Flageolet, flaj'ō-let, a small wind-instrument, the notes of which are exceedingly clear and shrill. It is a sort of whistle with a mouthpiece that is usually inserted in a bulb. It is generally made of box or other hard wood, though sometimes of ivory, and has six holes for the regulation of its sounds, besides those at the bottom and mouthpiece, and that behind the neck. Its compass is two octaves, and a set of five different sizes is needed to take all the semitones in this range. It was formerly used in the orchestra.



" Flagellata." (See page preceding)

Various Flagellata. A, Bicoseca; B, Englina vividis (Autoflagellatis); C, Noctiluca miliaris (Cystoflagellate); D, Ceratium tripos (Dinoflagellate).

princesses of his house, and to other pious friends, as marks of his peculiar favor.

The expectation of being purified from sin by flagellation prevailed throughout Europe in the last half of the 13th century. "About this time," says the monk of Padua in his chonicles of the year 1260, "when all Italy was filled with vice, the Perugians suddenly entered upon a course never before thought of; after them the Romans, and at length all Italy. Men of noble and ignoble birth, old and young, traversed the streets of the city naked, yet without shame. Each carried a scourge in his hand, with which he drew forth blood from his tortured body, amidst sighs and tears, singing at the same time penitential psalms." The penitents united into fraternities called the Flagellants (q.v.). After the Council of Constance (1414–18) both clergy and laity gradually abandoned flagellation. The Franciscan monks in France (Cordeliers) observed the practice longest.

Flagellation was sometimes voluntary and sometimes imposed as a penance. Henry II. of England allowed himself to be scourged at the

Flaget, flä-zhā, **Benedict Joseph**, American Roman Catholic bishop: b. Contournat Angergne, France, 7 Nov. 1763; d. Nazareth, Ky., 11 Feb. 1850. He was educated in France, came to America, and was made bishop of Bardstown in 1810. The name of his diocese was subsequently changed and he became bishop of Louisville in 1841.

Flagg, George Whiting, American artist: b. New Haven, Conn., 26 June 1816; d. Nantucket, Mass., 5 Jan. 1897. He studied art for six years in London, England, and on his return to the United States opened a studio in New York. He was elected a member of the National Academy of Design in 1843, and an academician in 1851. Among his best-known paintings are: 'Landing of the Pilgrims'; 'Washington Receiving His Mother's Blessing'; 'The Good Samaritan'; 'The Scarlet Letter'; and 'The Execution of Lady Jane Grey.'

Flagg, Isaac, American Greek scholar: **b.** Beverly, Mass., 7 Sept. 1843. He is a son of Wilson Flagg (q.v.) and was graduated **from**

Harvard 1864. He was professor of Greek at Cornell University 1871–88, and at the University of California since 1899, holding at the latter institution the chair of classical philology 1890–9. He is the author of 'Versicles'; 'Outlines of the Temporal and Model Principles of Attic Prose'; and has edited: 'The Hellenic Orations of Demosthenes'; 'The Seven Against Thebes, of Æschylus'; etc.

Flagg, Jared Bradley, American Episcopal clergyman and artist: b. New Haven, Conn., 1820; d. 1899. He studied art with his brother G. W. Flagg (q.v.), entered the Episcopal ministry in 1854 and was for several years rector of Grace Church, Brooklyn Heights, N. Y. He was especially noted for the excellence of his portraits. He published 'Life and Letters of Washington Allston' (1892).

Flagg, Wilson, American naturalist: b. Beverly, Mass., 5 Nov. 1805; d. Cambridge, Mass., 6 May 1884. He published: 'Studies in the Field and Forest' (1857); 'Halcyon Days'; 'A Year Among the Trees' (1881); and 'A Year Among the Birds.'

Flag'ler, Henry M., American capitalist: b. Canandaigua, N. Y., 1830. He began life as a clerk in a country store, then going to Saginaw, Mich., he became a salt manufacturer. He afterward removed to Cleveland, Ohio, and formed one of the firm of Rockefeller, Andrews and Flagler, now known as the Standard Oil Company, and with which he is still connected. He is the proprietor of some 600 miles of railroad in Florida and of the Ponce de Leon and Alcazar hotels at Saint Augustine.

Flagler, Isaac Van Vleck, American organist: b. Albany, N. Y., 15 May 1842. He studied at Paris under Batiste, and has since become famous as a church organist in the United States, being at present organist of the First Presbyterian Church, Auburn, N. Y. He has composed, among many organ pieces, 'Variations on an American Air.'

Flag'staff, Arizona, an important railroad town in Coconino County, on the Atchison, T. & S. F. R.R. It has an altitude of 6,935 feet. The town has extensive live-stock and lumber interests. Tourists going to the Grand Cañon of the Colorado make Flagstaff their base of supplies. Pop. (1901) 1,285.

Flambard, flam'bärd, **Ranulph** or **Ralph,** Norman prelate and statesman, d. 5 Sept. 1128. He was early connected with the Conqueror's court, and being handsome, clever, and unscrupulous, gained great influence with the king, and rose to still greater favor with Rufus, whom he encouraged in his tyrannical and rapacious courses. His flagrant extortions earned the hatred of the people, and his character is painted in the blackest characters by the chroniclers. In 1099 he was made Bishop of Durham; but on the death of Rufus he was committed to the Tower by Henry I. He managed to escape, however, by means of a rope conveyed to him in a vessel of wine, and instigated Robert, Duke of Normandy, to invade England. He was subsequently forgiven by Henry and restored to Durham, where he engaged in architectural works connected with the city and the cathedral. See Freeman, 'The Norman Conquest,' Vols. IV. and V.; Freeman, 'William Rufus.'

Flamborough (flam'bur-ō) **Head,** a bold promontory of England, on the Yorkshire coast, projecting a considerable distance into the sea; lat. 54° 7′ N.; lon. 0° 5′ W. This is at once the most striking and most celebrated headland on the east coast of Great Britain, rising 450 feet sheer above the sea, having on its summit a lighthouse, 214 feet high, showing a revolving light which is visible 21 miles. Vast caverns, haunted by myriads of sea-fowl, penetrate deeply through this headland. For the battle of Flamborough Head, see JONES, PAUL.

Flamboy'ant, a term applied to the decorated and very ornamental style of architecture of French origin, and employed in France contemporaneously with the Perpendicular style in England. One of the most striking and common features is the waving and somewhat flame-like arrangements of the tracery of the windows, panels, etc. The Church of St. Maclou, Rouen, erected 1432–1500, is said to be one of the finest specimens of this style.

Flame, any gas or gaseous mixture that is actively undergoing combustion. Solid bodies (such as coke) which do not contain volatile constituents become incandescent when they burn, but their combustion is not attended by the development of actual flame. The flames that appear to issue from such solid combustibles as wood and coal are in reality due to the combustion of gases that are distilled from the fuel by the intense heat, as may be very easily proved by subjecting these bodies to the same temperature in closed vessels which prevent the access of air. Abundant quantities of combustible gases are then given off, and these may be led away in pipes, or stored in tanks, to be burned at more convenient times or places. The gas that is obtained from coal in this way has been used for many years for purposes of illumination. The mixed gases that are evolved when wood is subjected to destructive distillation contain methyl alcohol, acetic acid, and many other organic substances; and in fact they constitute the chief commercial source of the two substances just named. (See ALCOHOL.) Flames are usually very hot and luminous, though in some cases there is but little light developed. The flame of a spirit lamp, for example, is barely visible, although it is intensely hot; and the flame of burning hydrogen is an even more striking case of the same sort. The luminosity of flames is due chiefly to the incandescence of tiny particles of solid carbonaceous matter that they hold in suspension, as has been proved by many ingenious experiments. When a piece of wire gauze is brought down over the flame of a candle, the gauze permits the gases that arise from the wick to pass through it, but it chills them so that they are no longer capable of combining with one another, and hence the flame does not extend above the gauze. This simple and instructive experiment enables the observer to examine the structure of the candle flame without the least difficulty, and shows it to be a hollow cone, burning only on the outside, where the oxygen of the air can mingle with the gases in sufficient quantities to support combustion. That the gases developed at the wick really do rise up through the gauze is easily proved by igniting them with a burning match. Flames may be colored, and often very brilliantly, by the presence within them of certain metallic salts. Thus sodium compounds produce a strong orange-yellow color, potassium a violet, and strontium a crimson. Advantage is taken of this fact for the production of gorgeous color effects in pyrotechny. In chemical analysis, too, the color that a given substance yields when placed in a hot but normally non-luminous flame often gives valuable information concerning its composition. See BLOW-PIPE ANALYSIS; SPECTROSCOPE.

Flame-flower. See TRITOMA.

Flameless Explosives, explosives containing ammonium nitrate, with or without ammonium oxalate, which are to be used in blasting in mines containing fire damp or combustible dust. As examples of such explosives we have «ammonite,» consisting of ammonium nitrate 87 to 89 per cent, and dinitronaphthalene 13 to 11 per cent; «amvis,» ammonium nitrate 88 to 91 per cent, dinitrobenzene and chloronaphthalene 4 to 6 per cent, and wood pulp 4 to 6 per cent; «bellite,» ammonium nitrate 82 to 85 per cent, and metadinitrobenzene 18 to 15 per cent; «benedite,» ammonium nitrate 93 to 95 per cent, and rosin 7 to 5 per cent; «Casteaux's explosive,» ammonium nitrate 90 per cent, nitrodextrine 10 per cent; «grisoutine,» ammonium nitrate 67 per cent, nitroglycerin 30 per cent, and nitrocotton 3 per cent; «nitroferrite,» ammonium nitrate 93 to 94 per cent, potassium forrocyanide 2 per cent, crystallized sugar 3 to 2 per cent, and «trinitronaphthalene» 2 per cent; «progressite,» ammonium nitrate 94 to 95 per cent, and aniline chlorhydrate 6 to 5 per cent, and «roburite,» ammonium nitrate 90 per cent, chlorodinitrobenzene 10 per cent.

Flamen, flā'men, a priest of ancient Rome consecrated to the service of a particular divinity. They were established by Numa and were at first three in number: *flamen Dialis*, the priest of Jupeter; *flamen Martialis*, the priest of Mars, and *flamen Quirinalis*, the priest of Romulus. These three constituted the *flamen majores*, and were always of the patrician class. Later twelve *flamen minores* were created, chosen from the plebeians. The *flamines* held office for life, but were removable for neglect of duty or contamination, and were required to resign and remain single upon the death of their wives, the *flaminica*, who assisted them in their duties and were governed by the same rules as their husbands. The *flamen* was distinguished by the *apex*, a conical cap in the top of which was fastened a pointed twig of olive wood bound at its base with a lock of wool. He was not required to take an oath, was an ex-officio member of the Senate, was entitled to the use of the *toga prætexta* and the curule chair. He was entitled to the assistance of a lictor, and for himself and for his house held the right of sanctuary and of pardon. He could not leave the city for a single night or sleep out of his own bed for three consecutive nights, mount or touch a horse, touch a dead body, or engage in a long list of occupations that were considered to contaminate him. The flamens were selected by the Pontifex Maximus from three candidates nominated by the pontifices. When the emperors were deified they had flamens, as the *flamen Augusti*. There were also *flamines curiales*, and a *flamen arvalium*. Consult Marquart, 'Romishe Staatsverwaltung' (1885).

Flameng, Francois, frän-swä flä-män, French painter: b. Paris 1859. He began his art studies under his father, Leopold Flameng (q.v.), the engraver, and studied subsequently under Cabanel, Hedouin and Jean Paul Laurens. He is an artist of distinguished ability as a figure painter, and among the most striking works of his are: 'The Girondins Summoned' (1879); 'The Bowlers' 1886); and 'Grolier and Alus,' which last hangs in the Grolier Club of New York.

Flamingo, flā-ming'gō, a peculiar web-footed bird of the group *Phœnicopteri*, which may be regarded as intermediate between the storks and the ducks, the long legs and necks giving it a resemblance to the former, while the webbed feet connect it with the latter. There are six species of true flamingoes, widely spread over the warmer regions of both hemispheres. Our North American species (*Phœnicopterus ruber*), once common all along the southern shores of the United States, but now almost exterminated even from Florida, and ranging southward to the Argentine Republic, is light vermilion with brighter wing coverts. The other forms are rosy white (scarlet on the wing coverts) with black wing-quills. All have small goose-like bodies, but the long legs and neck give them a height of four or five feet. Their most extraordinary part is the bill, which is large, swollen and bent upon itself so that the upper half is turned downward when the bird feeds, with its head twisted and crown downward. The edges of both upper and lower jaw are furnished with small transverse plates, which serve, as in ducks, for a sieve, allowing the escape of the mud, but retaining the small worms, crustaceans, mollusks, fishes, etc., on which the birds feed. The upper surface of the tongue is beset on the sides and base with flexible, recurved, horny spines. Flamingoes live and migrate in large flocks, warning one another of danger by a loud trumpeting note, which is the signal for the flock to take wing. When flying, they form a triangle.

They breed in companies in mud-flats or inundated marshes, where they spend most of their time wading about, raising up the mud into a small hillock, which is concave at the top so as to form a nest. In this hollow the female lays her one egg, and hatches it by sitting with her legs doubled up under her. The young, usually two in number, do not fly till they have nearly attained their full growth, though they can run very swiftly and swim with ease almost immediately after their exclusion from the shell. This bird was held in high repute among the luxurious Romans; and Apicius, so famous in the annals of gastronomy, is recorded by Pliny to have discovered the exquisite relish of the flamingo's tongue, and a superior mode of dressing it. When taken young they soon grow familiar, but they are not generally found to thrive in the domesticated state. The European flamingo (*P. roseus*) is abundant in marshy regions of Spain and southern France, and is found as far south as Cape Colony, and as far east as Lake Baikal. In northwestern India it may be seen in flocks numbering tens of thousands. Another very similar species (*P. minor*), but of less size and with the chin feathered, is found from Madagascar around the whole circuit of the shores of the Indian Ocean. Three

FLAMINGO (*Phœnicopterus antiquorum*).

other species are known in South America, *P. andinus* of the central Andes, the largest of the family; *P. jamesi*, of southern Peru and Chile, and *P. chilensis* of the region south of Brazil, which has greenish shanks. In addition to the various ornithologies, the reader may consult an article by H. A. Blake, 'Nineteenth Century' (December 1887); Chapman and Buck, 'Wild Spain' (1893); and F. M. Chapman, 'Bird Lore' (1902).

Flaminian (flā-min'i-an) **Way,** the northern road which led from ancient Rome. It was constructed by Gaius Flaminius the elder in 202 B.C. during his censorship, and led from Rome to Ariminum (Rimini) on the Adriatic, 222 miles. Remains of it are yet extant in various places.

Flamininus, Titus Quintius, tī'tus kwin'shi-us flam-ĭ-nī'nus, Roman general: b. about 230 B.C.; d. about 175. Elected consul in 198, he undertook the conduct of the war against Philip II. of Macedon. By pretending that his object was to remove from Greece the Macedonian yoke, he detached many of the Greek states from Philip, and defeated him at Cynoscephalæ (197) in Thessaly. By the treaty soon after concluded Philip surrendered all the Greek towns which he possessed in Europe and Asia, and paid a heavy contribution to the Romans. At the Isthmian games in 196 Flamininus proclaimed, to the great joy of the assembled Greeks, the freedom of those states which had been subdued by Macedon. In 195 he diminished the power of the tyrant Nabis of Sparta, after which he occupied himself in restoring internal peace and prosperity to Greece.

Flaminius, Gaius, ka'yus flā-min'i-us, Roman general: d. 23 June 217 B.C. He was tribune of the people in 232, consul in 223 and 217, and censor in 220. As tribune he carried against the opposition of the senate an agrarian law. In his first consulship he with his colleague attacked the Gauls beyond the Po, and was defeated. The senate then recalled the consuls, but Flaminius resisted the order by refusing to open the letter, and obtained a victory over the Insubrians. A triumph was refused him on his return, but he was rewarded with demonstrations of popular favor. The circus Flaminius and via Flaminia were the monuments of his censorship. In his second consulship he marched against Hannibal, and rashly giving battle, was slain near Lake Thrasymenas.

Flammarion, Camille, kä-mēl flä-mä-rē-ôṅ, French writer on astronomy: b. Montigny-le-Roi (Haute-Marne), 26 Feb. 1842. In 1858 he entered the Paris observatory as pupil, being transferred in 1862 to the Bureau des Longitudes, where he remained till 1866. Although still a youth, he had already published the first of his many works, namely: 'La Pluralité des Mondes habités' (1862; 36th ed. 1892); 'Les Mondes imaginaires et les Mondes réels' (1865; 21st ed. 1892); and 'Les Merveilles Célestes' (1866; 7th ed. 1881). For five years from about 1868 he made a study of the upper regions of the atmosphere during several balloon ascents. In 1882 he founded the monthly magazine 'L'Astronomie,' and in 1887 started the French Astronomical Society. M. Flammarion has gained considerable fame for original researches in astronomy, especially in connection with double and multiple stars, colors of stars, sun-spots, and the proper motion of the stars; but is much better known for his excellent, well-written and accurate popular hand-books. Among his other works are: 'Etudes et Lectures sur l'Astronomie' (1867–80); 'Dieu dans la Nature' (1867; 22d ed. 1892); 'Lumen' (1872; 40th ed. 1890); 'Voyages en Ballon' (1870; 20th ed. 1889); 'Vie de Copernic' (1872); 'L'Atmosphère' (1872); 'Histoire du Ciel' (1873); 'Petite Astronomie' (1877); 'Les Terres du Ciel' (1877); 'François Arago' (1879); 'Astronomie Populaire' (1880); 'Les Etoiles et les Curiosités du Ciel' (1881); 'Le Monde avant la Création de l'Homme' (1886); 'Les Tremblements de Terre' (1886); 'Uranie' (1889); 'Qu'est-ce que le Ciel' (1891); 'La Planète Mars et ses Conditions d'Habitabilité' (1893). Several books have been translated into English.

Flam'steed, John, English astronomer: b. Denby, near Derby, 19 Aug. 1646; d. Greenwich 31 Dec. 1719. He began his mathematical and astronomical studies at an early age, and in 1675 took orders in the Established Church. He still continued his astronomical observations, and was in constant correspondence with scientific men. He found the astronomical tables of the day to contain large errors, and was anxious to make more detailed and accurate observations. This having come to the knowledge of Charles II., he was appointed astronomical observer to the king, and carried on his observations at the Queen's House at Greenwich, until the observatory was built for him in 1676. Here he passed the remainder of his life amidst his astronomical labors, which are considered as the foundation of modern practical astronomy. He was so ill supported that he had to teach for his own support, and erect instruments at his own expense. In 1684 he was presented with a small living, and his father dying in the same year, he was enabled to provide some needful apparatus at his own expense, which, on his death, was claimed by the government as public property.

Flan'ders, Henry, American lawyer: b. Sullivan County, N. H., 13 Feb. 1826. He studied law and since 1850 has practised his profession in Philadelphia. He has published: 'Maritime Law' (1852); 'The Law of Shipping' (1853); 'Lives of the United States Chief Justices' (1855–8); 'An Exposition of the Constitution of the United States' (1869); 'Law of Fire Insurance'; 'Adventures of a Virginian.'

Flanders (French, *Flandre;* German and Flemish, *Flandern;* Dutch, *Vlaanderen*), a former country or district of Europe, now included in Holland, Belgium, and France. It stretched from the Schelde, below Fort Lillo, west along the Hond, or West Schelde, and west-southwest along the German Ocean to the entrance of the Straits of Dover, near Gravelines, and was bounded east by the duchy of Brabant, south by Hainaut, and west by the French provinces of Artois and Picardy. The origin of the name is unknown. It occurs for the first time, but in a very restricted sense, in the 7th century. The erection of the territory into a county took place in the 9th century, and was made by Philip the Bold, king of France, in favor of his son-in-law, Baldwin, of the Iron Arm. It afterward passed to the united houses of Spain and Austria, and ultimately to the latter, but underwent considerable curtailment by the conquests of the French in the west, when part of it became French Flanders, and is now included in departments Nord and Ardennes; and by the conquests of the Dutch in the north, who succeeded in including the most northerly portion of it in the province of Zeeland. The remainder still retains its ancient name, and forms the modern provinces of East and West Flanders, in Belgium (q.v.).

Flanders, East (Fr. *Flandre Orientale*), a province of Belgium, bounded north by Holland, east by the provinces of Antwerp and Brabant, south by Hainaut, and west by West Flanders; length, north to south, 34 miles; central breadth, east to west, 32 miles; area, 1,158 square miles. The surface forms an extensive plain, sloping gently eastward. It wholly belongs to the basin of the Schelde, which by itself, its tributaries, and canals connected with them, furnishes ample water communication. Its soil, partly of a sandy and partly of a clayey nature, is so industriously and skilfully cultivated that it has the appearance of a vast garden, and presents one of the richest rural landscapes which anywhere exists. The principal crops are wheat and flax, but almost all the plants which can be grown under the same latitude are cultivated with success. There are no forests properly so called, but owing to the general practice of planting hedge-row trees, there is no want of wood. In general, however, it consists of poplar and other soft-wood trees, and makes only indifferent timber. There are no minerals of any value, but manufactures have made great progress, and all the ordinary, as well as the fine tissues of wool, cotton, and flax, are well and largely made. There are also numerous tanneries, breweries, distilleries, soap-works, roperies, sugar and salt refineries, etc. The trade includes, in addition to these articles, flax, hops, and oil. For administrative purposes the province is divided into six arrondissements — Gand, or Ghent, the capital; Alost, Audenarde, Termonde, St. Nicolas, and Eecloo. Pop. (1901) 1,029,971.

Flanders, West (Fr. *Flandre Occidentale*), a province of Belgium, bounded north and northwest by the German Ocean, west-southwest and south by France, southeast by the province of Hainaut, east by East Flanders, and northeast by Holland; greatest length, north-northeast to south-southwest, 54 miles; greatest breadth, 48 miles; area, 1,249 square miles. The surface is generally flat, but a few low hills occur in the south and east, and a range of sand hills or downs lines the greater part of the coast. The most important crops are flax, both abundant in quantity and excellent in quality; oats, barley, hops, oil-seeds, tobacco, madder, and chicory. The cattle, of all sorts, are of excellent breeds; and fish, poultry, and game abound. The most important branch of industry is linen, ordinary and damask. Great quantities of lace also are made, and there are numerous breweries, distilleries, tanneries, dye-works, oil-works, soap-works, salt and sugar refineries, etc. The province is divided into eight arrondissements — Bruges (the capital), Courtrai, Ypres, Furnes, Thielt, Roulers, Ostend, and Dixnude. Pop. (1901) 805,236.

Flandin, Eugène Napoléon, nä-pō-lā-ôṅ ė-jen flăṅ-dăṅ, Italian painter and archæologist: b. Naples, Italy, 15 Aug. 1809; d. Tours, France, 1876. He published: 'Etudes sur la Sculpture Perse' (1842); 'Etudes sur la Perse moderne' (1842); 'Relation du voyage in Perse' (1843). In 1843–5 he traveled with Botta through the country of the Tigris, and illustrated his fellow traveler's 'Monuments de Ninive,' with drawings of the sculptures of Khorsabad. He finally made a full artistic exposition of Oriental life in his elaborately illustrated work, 'L'Orient' (1856); and also wrote 'Histoire de chevaliers de Rhodes' (1854).

Flan'drau, Charles Macomb, American writer of fiction: b. Minnesota 1870. He is the author of 'Harvard Episodes'; 'The Diary of a Freshman.'

Flan'drians, or **Flemings**, a subdivision of the Mennonite Anabaptist sect. They arose in the 16th century, and were rigid in their procedure. In 1630 A.D. the majority of them entered into a union, confirmed in 1649, with their more moderate brethren, who were often called Waterlanders.

Flandrin, Jean Hippolyte, zhoṅ ē-pō-lēt flăṅ-drăṅ, French historical and portrait painter: b. Lyons 23 May 1809; d. Rome, Italy, 21 March 1864. He worked under Ingres, and from him he imbibed that love of severe and definite form and that classical feeling which he used for his own ends in his religious painting. In 1832 he won the Prix de Rome by his 'Recognition of Theseus'; and before his five years' residence in Italy was completed he had produced his 'St. Clair Healing the Blind,' now in the cathedral of Nantes. Henceforward he was mainly occupied with decorative monumental work, though he also executed many admirable portraits. In 1842 he began his great frescoes of 'Christ Entering Jerusalem,' and 'Christ Going up to Calvary,' in the sanctuary of the Church of St. Germain-des-Près, Paris, deeply impressive works, which already entitled their painter to rank as the greatest religious painter of the century. The choir of the same church he adorned (1846–8) with figures of the Saints and the Virtues. He also decorated the Church of St. Paul at Nimes (1847–9), the Church of St. Martin d'Ainay at Lyons (1855), and painted the frieze of St. Vincent de Paul, in Paris, with a noble series of saints and martyrs. In 1855 he began his last great work in the nave of St. Germain-des-Près, consisting of subjects from the Old and New Testaments, of which some were left uncompleted at his death, at Rome, 21 March 1864. His 'Lettres et Pensées,' with a memoir and a catalogue of his works, were issued 1865. See 'Lives,' by Poncet (1864); 'Montrard' (1876).

Flandrin, Jean Paul, zhoṅ pōl, French painter: b. Lyons 8 May 1811; brother of the portrait and historical painter Hippolyte Flandrin (q.v.), and a landscape painter whose compositions are of an ideal character and represent a survival of the classical school of Poussin and Claude.

Flan'nan or **Flan'nen Islands**, or **The Seven Hunters**, a group of small rocky islands in Scotland, in the Outer Hebrides, included in the county of Ross and Cromarty, about 15 miles west-northwest of Gallon Head. They are frequented by large numbers of sea-birds, and sheep used to be pastured on some of them. There is a lighthouse of recent erection, standing at a height of over 200 feet, the structure itself being 75 feet high, with a light visible 24 miles.

Flannel, a woolen fabric of more or less loose texture and various degrees of fineness, much used as an article of clothing both in hot and cold countries, and for outer as well as inner garments, being very commonly worn next the skin. Flannel made in Wales from the wool of the native mountain sheep has the highest reputation.

Flannel-mouth, a local name for the great Mississippi catfish (*Ameiurus lacustris*). (See CATFISH.) Another fish, one of the suckers (*Catostomus latipinnis*) is so called in the neighborhood of the Rio Colorado.

Flannen Islands. See FLANNAN ISLANDS.

Flash, Henry Lynden, American author: b. Cincinnati, Ohio, 20 Jan. 1835. He served during the Civil War as volunteer aide on the staffs of the Confederate Gens. Hardee and Wheeler; and later edited the ‹Telegraph› and ‹Confederate› in Macon, Ga. He was the author of ‹Poems,› and of many popular ballads which appeared during the Civil War.

Flashlight, Electric. See FOG SIGNALS.

Flat Foot, or **Pes Planus**, a very common deformity of the foot due to a loss of the natural arch. A strong ligament holds the os-calcis and astragalus in such a position that an arch is formed by the bones of the foot and the weight of the body is transmitted through that arch. There is a congenital variety that is said to be due to lack of the normal fatty pad in the hollow of the new born infant's foot. During the first five years of life this fatty pad takes the place of the bony arch and if the pad be lacking the arch does not develop. The acquired variety affects those suddenly called upon to stand for long hours upon the feet. A very large number of nurses and soldiers and policemen suffer more or less with this deformity in their early months of training. Rickets, knock-knees, sprains and badly set fractures of the leg may give rise to flattening of the arch.

The bones are not changed from their normal shape except in the very young, but their relation to each other is altered. There is also a stretching of the extensor tendons of the foot and the muscles and fascia of the sole. Besides the flattening of the foot there is a more or less marked turning out of the toes and a tendency to walk on the inner side of the foot. This gait becomes quite characteristic.

In the acute cases particularly there is apt to be severe pain in the spring ligament, the inner malleolus or the ball of the great toe. Because of this, the affection is very commonly thought to be rheumatism, gout, or disease of the bone.

The normal marking of the sole of the foot is an impression of the heel, a narrow margin of the outside of the foot and a broad line made by the ball of the foot. When the arch becomes weakened there is a gradual increase of the outer margin until almost the whole foot makes its impression. This simple test is of great value.

Congenital flat foot may be greatly improved if discovered in time by manipulative massage, bandaging and the use of supports until the bony arch is formed. Acute cases of flat foot in adults sometimes require rest for a time. Properly made shoes without braces frequently suffice to prevent a return of the trouble. Others require the constant use of felt or well-adjusted steel springs in the shoes. Exercises of the extensors of the foot, massage and electricity are of value.

The bad cases of deformity that cannot be corrected require operation under an anæsthetic, the joints being forcibly freed and kept in normal position by plaster cast for a period and then kept up by a support.

Flat'bush, New York, formerly a town in Kings County, Long Island, but since 1900, a part of the borough of Brooklyn, New York. Before being incorporated in the city Flatbush had a population of 15,620. The locality is of considerable historic interest, having been the scene of a part of the battle of Long Island, 27 Aug. 1776.

Flatfish, a fish of the *Heteromomata*, including the families *Pleuronectidæ* and *Soleidæ*, which are characterized by their greatly compressed form, distorted skulls and the habit of lying and moving on the side. They are somewhat related to the cod family, and inhabit the seas of all parts of the world, more than 500 species, classified in some 55 genera, being known to ichthyologists. All are oval or elliptical in outline, very thin and flexible, and habitually rest, half covered, or move sidewise along sandy sea-bottoms, some species near shore, or even ascending rivers, others only in deep water. They are carnivorous, taking as food mainly mollusks, worms, sand-dollars and the like, found in such places, for the crushing of whose shells they are provided with strong teeth, chiefly developed on the inferior side of the mouth. The flatness of these fishes is not a broadening laterally but a compression of the body whereby they become high and thin in a dorso-ventral direction, lie over on one side (usually the left), and have the head permanently twisted to the side uppermost in their customary position. This, however, comes about only with age. The very young flatfish are born in the normal shape of fishes, and swim in the ordinary vertical position, but soon begin to assume the adult peculiarities. This tendency causes profound changes in structure. The skull gradually becomes so distorted that its facial part is twisted at right angles to the plane of the cranial part, and both eyes, set close together, look upward, so that the fish has a seeing and a blind side. In order to get into this position the eye of the under side is rotated around, or in some species right through the young skull, when the fry is only an inch or so in length and the bones not yet ossified. The curious condition of the dorsal fin in the flatfish is nevertheless a greater mark of distinction. The external ethmoid bone belonging to the blind side is much enlarged, and sends back a process outside the eye belonging to that side to meet another process from the cranial region of the skull. Thus, says Cunningham, the eye which has migrated is enclosed in a complete bony orbit, while the other (lower) eye is merely bounded on its outer side by the jaw muscles. It is on this bony bridge entirely foreign to the anatomy of an ordinary fish that the dorsal fin is supported, and is able to extend from the tail clear to the snout, not passing between the eyes, but separating the hidden from the exposed side. Similarly the ventral and anal fins form a continuous growth along the ventral keel, defining there the upper side from the lower. The lesser forward fins, like the mouth, are usually asymmetrical. They are able to swim well when they please, and sometimes appear at the surface, progressing with a curious sideways undulatory movement very graceful. This is a dangerous excursion, however, and flatfish as a rule cling to the bottom, trusting to be overlooked because of their close resemblance to the sand or mud.

The young flounder or other species is brown on both sides alike; but when it turns on one side and lies flat, the under side becomes nearly white while the upper assumes the color of the bottom upon which the fish habitually rests. This is an excellent example of protective resemblance. (See COLORATION, PROTECTIVE); and that it arises from the habits of the fish and is the effect of persistently keeping the under side in shadow, is plain from the fact, demonstrated by experiment, that when flatfish are confined in aquaria with glass bottoms, through which light is reflected upon the under side, color will develop there. Some flatfish are spotted, increasing their likeness to a pebbly bottom. All these circumstances make it evident that flatfishes originated from symmetrical ancestors related to those of the cod, but what were the inducing causes of the extraordinary changes that have characterized their evolution are not plain. Little help is derivable from palæontology for fossil flatfishes are extremely rare, the oldest known being a sole-like form from the Upper Eocene of southern Europe.

The group includes two families, the flounders (*Pleuronectidæ*) and the soles (*Soleidæ*). Jordan subdivides the former into three sections, namely *Hippoglossinæ*, halibut tribe; *Pleuronectinæ*, flounder tribe; and *Psettinæ*, turbot tribe. The soles are a small family distinguished by the hidden, adnate character of the gill-cover, the small, much twisted eyes and mouth, and the absence of teeth. The whole group yields excellent flesh, and furnishes some of the most important food-fishes of commerce as well as several regarded as especial delicacies. They are treated of at length in Goode's 'Fishery Industries,' Sec. 1 (1884); and in Jordan and Evermann's 'Fishes of North and Middle America' (1898). See FLOUNDER; FLUKE; HALIBUT; PLAICE; SOLE; TONGUE-FISH; TURBOT; WINDOWPANE.

Flathe, Heinrich Theodor, hīn'riH tā'ō-dōr flä'tĕ, German historian: b. Tanneberg, near Nossen, Germany, 1 June 1827. He attended the Fürstenschule in Meissen, studied philology and history in Leipsic and in 1867 was appointed teacher in the Fürstenschule at Meissen. His main achievement was the revision and rearrangement of F. W. Bottiger's 'Geschichte des Kurstaats und Königreichs Sachsen' (1867), which he transformed into a new work, for he not merely added new details, but rewrote much of the main argument. He has also among other works written 'Allegemeine Weltgeschichte' (1883).

Flathead, or (properly) **Salish Indians**, a tribe of Indians with uncompressed skulls, as distinguished from the «peaked-heads» who did compress their skulls, and who gave the others the name of Flatheads. These Flatheads are a superior tribe, originally dwelling around the Flathead Lake and River in northwestern Montana; much respected by the traders and explorers as at once very brave against their enemies (chiefly the Blackfeet) and honorably requiting friendly treatment. The famous Flathead mission, the most successful in the Northwest, was established among them in 1841 by the Jesuit missionary P. J. De Smet. They are now located on the Jocko reservation in their old territory, confederated with the Pend d'Oreilles and joined with the Kootenais, the whole numbering 1,280.

Flather, John Joseph, American mechanical engineer: b. Philadelphia, Pa., 9 June 1862. He was graduated from the Sheffield Scientific School of Yale, and after several years' experience in American and foreign machine shops was instructor in mechanical engineering at Lehigh University 1888–91; professor of the same at Purdue University 1891–8; and he has filled a similar post at the University of Minnesota from 1898. He has published: 'Treatise on Steam Boilers' (1889); 'Rope Driving' (1892); 'Dynamometers and the Measurement of Power' (1900).

Flat'tery, Cape. See CAPE FLATTERY.

Flat'ulence. See INDIGESTION.

Flatworms, worm-like animals of the phylum *Platyhelminthes*; especially those of the order *Turbellaria*, characterized by oval outline and decided flatness of body. See *Classification* in article ANATOMY; also PLANARIAN WORMS.

Flaubert, Gustave, güs-täv flō-bār, French novelist: b. Rouen, France, 12 Dec. 1821; d. Rouen 8 May 1880. His greatest novel was his first, 'Madame Bovary' (1857). He next wrote a historical novel, 'Salammbô,' the scene laid in the most flourishing period of Carthage — a splendid description of ancient Punic life, but having lively interest as a story; 'The History of a Young Man' (1869), like 'Madame Bovary,' a pessimistic picture of social life; 'The Temptation of St. Anthony' (1874), a piece of imaginative writing dealing with philosophical problems; and 'Three Stories' (1877), which had a favorable reception. The posthumous novel, 'Bouvard and Pécuchet' (1881) is a satire on humanity in general. His comedy, 'The Candidate' (1874), failed on the stage. See Tarver, 'Gustave Flaubert' (1895); Faquet, 'Flaubert' (1899).

Flav'el, John, English Nonconformist: b. Bromsgrove, Worcestershire, about 1630; d. Exeter 29 June 1691. He was graduated at Oxford University, inducted into the rectory of Dartmouth, Devonshire, in 1656, but dispossessed and ejected for nonconformity in 1662. During the remainder of an active ministry he preached from house to house and wrote devotional works, which were long popular, and among which are: 'Husbandry Spiritualized' (1669); 'Divine Conduct' (1678); 'The Touchstone of Sincerity' (1697); 'The Soul of Man' (1698); etc.

Flavian Cæsars, flā'vi an sē'zarz, the Roman emperor Vespasian and his sons and successors, Titus and Domitian, who were of the house of Flavius.

Flav'in, a yellow or orange dyestuff. American flavin is got from quercitron bark, and is said to be the same as quercitrin.

Flax (*Linum usitatissimum*). The use of flax has a greater antiquity than any other commercial fibre. It was cultivated and manufactured by the Swiss lake dwellers in the Stone Age in Europe, well preserved specimens of straw, fibre, yarn, and cloth being preserved in the museums. This ancient flax, however, was from another species, *Linum angustifolium*. The Egyptians produced and used flax thousands of years ago, and the Chaldæans and Babylonians carried its use to the highest state of textile development. Three thousand years ago the Phœnicians extended the culture, and the Greeks and Romans made it a household industry, and it became the aristocratic fibre. It is claimed that the ancient Mexicans knew of both flax and hemp, and its culture in this country goes back to the earliest date of our civilization.

A bast fibre, it may be considered, next to cotton, the most valuable and universally employed textile in the whole range of vegetable fibres. While the plant can be grown in nearly every portion of the temperate world, it is produced commercially in Great Britain and Ireland, Denmark, Sweden, Belgium, Holland, France, Germany, Russia, Austria, Spain and Portugal, portions of Africa and Asia, Japan and the Australian colonies. It thrives in Canada, the United States, and Mexico and in some of the South American countries. Good flax has been grown as far north as Alaska, and the flax of Archangel is famous.

Its cultivation was brought to this country by the American colonists, the records showing that considerable quantities were grown in eastern Massachusetts as early as 1630. Its growth was early extended to other States, though for the most part it was a household rather than commercial industry. In the fifties of the last century three quarters of a million pounds of flax were produced in the United States, Vermont, Connecticut, New York, and New Jersey leading in the culture. With the increased use of cotton fine flax culture steadily declined, and while, as late as 1869, 13,000 tons of flax were produced, a very small proportion was fine line, the bulk being mere tow for the bagging factories. A year or two later, when jute was admitted free of duty, the industry collapsed, At the present time we are growing flax to the extent of a million acres annually, but for the seed, for linseed-oil manufacture, and not for the fibre. The straw, which is rough and coarse, is largely thrown away, although in recent years attempts are being made to use the rough product for paper.

Good commercial fibre could be grown in many localities, notably in Michigan, Wisconsin, Minnesota, Oregon, and Washington. In a series of government experiments, conducted by the writer in the Puget Sound region of Washington, flax-straw was produced from which was hackled out a fibre valued by experts at $500 per ton. Very little line flax is produced at the present time, however, our commercial supply coming largely from Russia, Holland, Belgium, and Ireland; a little comes from Italy and Canada. Much of the "Irish flax" is grown in Belgium and sent to Ireland for preparation.

Nearly every country producing commercial flax has established grades and marks save the United States and Canada. In portions of Russia the grades bear the names of the districts where grown. The grades of Archangel flax are known by the terms first, second, or third Crown, etc., and first Zabrack, second Zabrack, while Riga flax is graded from the standard K as HK, PK, HPK, HSPK, etc. Holland flax is graded by roman numerals or by double numerals, as $\frac{\text{II}}{\text{IV}}$ $\frac{\text{I}}{\text{V}}$ VI, VII, etc., Belgian flax also by numerals except Friesland flax, which is lettered, as D, E, Ex, F, Fxx, and so on to Gxxx. French flax is known by the districts where produced and Irish flax by the counties where the flax is grown (see 'Descriptive Catalogue Useful Fibre Plants of the World,' p. 222). Our importations of all kinds of raw and hackled flax last year amounted to 8,466 tons, worth $2,227,141.

The culture of flax requires a deep, well-tilled soil, in high state of fertility, such as moist, deep, strong loams upon upland; a wet soil is disastrous and clays are therefore avoided; and a soil filled with the seeds of weeds is equally fatal to flax culture. The land must be deeply plowed and reduced to fine tilth by harrowing and rolling. In the preparation of the soil, especially in Europe, a systematic rotation of crops is practised, flax occupying the same land not oftener than once in 5 or 10 years. Imported Riga seed gives the best results, although Belgian Riga (Belgian seed produced from one sowing of Riga seed) gives a fine fibre. The common seed of the oil-mills should never be used for fibre culture. When flax is grown for the production of seed alone, to be sold to the oil-mills, the ground is seeded at the rate of two to three pecks to the acre. For fibre culture one and a half to three bushels is the proper quantity per acre.

After the seed has vegetated and is about two inches high the weeding begins, for no fine flax can be produced if the crop is choked with weeds. Flax is harvested by pulling the straw out of the ground roots and all, the straw being laid in handfuls to dry, and afterward made into bundles, which are stacked in the field. Practice varies, however, in different countries as to the handling before the retting period. In Flanders the greatest care is given to drying and storing, in order to keep the flax clean and bright for the final process of retting.

There are three methods of soaking or retting the straw: Dew retting is the simplest and the least careful, the straw being spread over the field like hay, to be retted by the dew, and by the action of the elements. Pool retting is practised by immersing the straw in pools of stagnant water, the softest water giving the best results. The pools are dug in the ground for the purpose, though a great deal of the Irish flax is retted in "bog holes." Retting in running water is the third method, this form of retting being practised in Belgium; the famous Courtrai flax is retted in the sluggish and murky waters of the river Lys, the straw, in bundles, being placed in large crates and weighted with paving stones until the crates sink sufficiently to fully cover the flax. The flax of Courtrai, retted in the Lys, is the finest flax in the world. It is very light in color, clean, and even, and shows a superior tensile strength. The flax is given two immersions, the straw being taken from the crates and carefully dried before the second immersion.

The first operation in cleaning or extracting the fibre is to pass the straw through a breaker, which loosens the woody portions of the stem, and reduces them to fragments, to facilitate the next operation, the scutching, which whips out the «chive» and all waste matters and leaves the pure flax fibre. In former times the scutching was done by hand, though now machinery is generally used. The scutched flax is subsequently hackled or dressed by repeated combings, which removes the short and broken or tangled fibre, these combings producing tow. Each hackling adds to the quality of the fibre, and of course to the cost. Flax is usually imported in the scutched form, the hackled flax known as «dressed line.» The cheaper grades of flax come from Canada and Russia, the medium and finer grades from Holland, Belgium, and Ireland. The product is used in the United States for threads, twine, and crash, as no fine linen is woven in America. Mexico produces some good flax, and there are linen mills in Mexico city which produce fair grades of fabric. For the details of flax culture and manufacture, consult 'Special Reports' (Nos. 1, 4, and 10), office of Fibre Investigations of the Department of Agriculture; 'Spinning the Threads,' by A. R. Turner, Jr., in Jubilee number of 'New York Dry Goods Economist,' and (Etudes sur La Culture le Rouissage et el Teillage du Lin,' by Alfred Renouard. See CORDAGE; CORDAGE INDUSTRIES; FIBRE; LINEN.

CHAS. RICHARDS DODGE,
Commercial Fibre Expert.

Flax'man, John, English sculptor and draughtsman: b. York, England, 6 July 1755; d. London 7 Dec. 1826. From his earliest years he exhibited and cultivated his talent for designing, and was also attracted by the picturesque conceptions of Greek mythology. He began to study at the Royal Academy in 1770, earning for some time a living by making designs for Wedgwood, the potter, and other persons. He went to Italy in 1787, and acquired the highest reputation by three series of designs, the illustrations to Homer, Æschylus, and Dante. He became a member of the Royal Academy 1797, and professor of sculpture there in 1810. The monument to Lord Mansfield in Westminster Abbey, the group of 'Cephalus and Aurora,' 'Psyche,' the group of the 'Archangel Michael and Satan,' are among his best works. He executed many exquisite bassi-relievi, compositions from Scripture subjects, and marked by some special religious sentiment. The monuments to Nelson, Howe, and Reynolds in St. Paul's are by his hand. One of his latest and finest productions is the 'Shield of Achilles.' The sculptures and sketches of Flaxman are now deposited and exhibited in a gallery called the «Flaxman Hall,» at University College, London. His 'Lectures on Sculpture' appeared in 1829, passed through a new edition in 1866.

Flaxseed, the seed of the flax plant (*linum*) largely used for domestic and medicinal purposes, produced in large quantities in the south of Europe, Egypt, parts of Asia and in the United States. (For a detailed description of the plant see FLAX; and for its commercial qualities other than seed, see FIBRE and LINEN.) The seeds of flax are dark brown, glossy, oval oblong, flattened, with acute edges, and pointed at one end. The seed is rich in an oil of such superior drying qualities as render it an indispensable ingredient in paint and varnish, and in the manufacture of linoleum, oilcloth, printer's ink, patent leather and other products and manufactures. The cultivation of the plant for fibre requires harvesting before the seed is fully ripe, which impairs the quality and reduces the quantity of the crop of flaxseed. The cultivation of flax for the seed requires a seeding of 2 or 3 pecks to the acre, and while it yields an increase of seed, the fibre straw is coarser; hence flax must be raised exclusively either for fibre or for seed. European countries cultivate flax for fibre, while the United States, Argentine and British India produce the world's commercial crop of flaxseed.

Introduction in America.— Flax for fibre was introduced in the United States soon after the landing at Plymouth. The seed for which there was obviously a limited domestic demand, gradually developed as an article of commerce. So long ago as 1791 the exports of flaxseed from the United States amounted to 292,460 bushels. In the same year began the manufacture of linseed oil in this country. In 1810 there were 283 linseed oil mills located in 14 States, 171 mills being in the State of Pennsylvania. The total annual output of these mills amounted to 770,583 gallons, representing 300,000 bushels of seed. In 1839 the first cargo of flaxseed ever brought into the United States was imported from Russia, and a few years later ships carrying ice to India brought flaxseed on the return voyages. From 1850 to 1870 India shipped a larger quantity of flaxseed to the United States than was produced in this country. From 1850 to 1860 half the entire crop here was grown in Ohio and Kentucky. The linseed oil mills divided or arranged themselves about 1891 into two groups, eastern and western. The former utilized the India imports of seed, while the western mills used the home product. In 1892 the United States took rank among the surplus flax-producing nations of the world and became an exporter of importance. In 1894 a short crop necessitated the import of 4,000,000 bushels. In 1903 there were 13 mills of large capacity in the Eastern States, 4 in Buffalo, 2 in New York, 3 in Philadelphia and other individual mills at Pittsburg and Allegheny, Pa., and Troy and Amsterdam, N. Y. These combined mills crush annually upward of 12,000,000 bushels of seed.

The Western Crop.— The flaxseed industry has migrated from its original western home in Ohio and Kentucky, State by State, until its present area includes North Dakota, South Dakota, Minnesota, Iowa and Wisconsin (known as the northwestern crop), and in Kansas, Missouri, Nebraska, Oklahoma and Indian Territory (known as the southwestern crop). Up to 1869, Ohio was the leading producing State. In 1879 Illinois produced the largest crop, 1,812,438 bushels. In 1889 North Dakota took the lead with a production of 7,776,610 bushels, and in 1902, out of a total production in the United States of 29,284,880 bushels North Dakota produced 55 per cent or 15,552,000 bushels. There are two varieties of seed produced in the West.

The small-grained seed of the Southwest yields an average of 17 pounds of oil to the bushel, while the larger-grained seed of the Northwest yields 20 pounds of oil to the bushel (56 pounds).

PRODUCTION OF FLAXSEED IN THE UNITED STATES.

District	1849	1879	1902
	Bushels	Bushels	Bushels
Northwestern crop......	315,506	6,010,700	26,966,600
Southwestern crop......	13,696	970,956	1,856,240

Russia	18,022,000	16,194,000
Argentine	8,639,000	15,354,000
British India................	17,116,000	13,041,000
Austria	735,500	1,131,000
France	345,000	611,000
Other countries..............	1,511,100	1,910,000
Total	66,347,600	72,241,000

The manufacture of linseed oil in the West has become largely localized in cities on and near the Great Lakes. There were 5 mills in Minneapolis in 1902, 6 in Chicago, 2 at Toledo, and 1 each at Cleveland, Milwaukee, South Bend, Ind., and Redwing, Minn. In the northwestern States of Iowa, North and South Dakota, there are but 3 mills, the bulk of all the western crop going to Chicago. Flaxseed in its natural state has no domestic uses on the farm, so that internal commerce involves the entire crop.

Flaxseed Products.— The principal product as understood is linseed oil. The residue after the extraction of the oil is the by-product the oilcake, a valuable cattle food, which, when ground, is known to commerce as linseed oil meal. Out of a crop like that for 1902 (29,000,000 bushels), there could be manufactured over 67,000,000 gallons of oil and upward of 1,000,000,000 pounds of oilcake. Of this vast quantity of oil the foreign demand only amounts to 100,000 gallons a year. Linseed oil has many uses and the monopoly of its field is so complete it has no substitutes nor adulterants. Probably 75 per cent of the oil manufactured is compounded with pigments and gums and used as paint and varnish. The remainder is utilized in making linoleum, oilcloth, printer's ink, waterproof fabrics not made of rubber, enamel for buttons, for making soap and for a few medicinal purposes. The oilcake, used only as a cattle food finds an extensive market abroad. It is highly prized by European stockraisers, but little appreciated in America. About 80 per cent of the oilcake product is exported. Belgium alone bought 148,263,752 pounds in 1901. In the fiscal year 1901–2 oilcake to the value of $5,665,392 was shipped to foreign countries, and the average amount exported for five years prior to 1902 was 488,891,125 pounds. In the manufacture of linseed oil from flaxseed two processes are used, one known as the «old» or hydraulic press process, and the other as the «new» or naphtha process. The old process is in use generally throughout the United States, the new process being represented in 1902 by a single mill in Chicago. In December 1902 there were 40 linseed oil mills in operation in the United States. They contained 750 presses with a crushing capacity, if operated 250 days in the year, of 25,000,000 bushels, with an output of 70,000,000 gallons of oil.

AVERAGE PRICE OF FLAXSEED (PER BUSHEL).

Month	1891	1901	1902
January	1.19¼	1.66½	1.65¼
April	1.20¼	1.61	1.72½
July	1.03¼	1.84½	1.55
October	.95½	1.49½	1.19½

ACREAGE, PRODUCTION, AND VALUE OF FLAXSEED IN THE UNITED STATES IN 1902.

States and Territories	Acreage	Yield per acre	Production	Price per bushel Dec. 1	Farm value Dec. 1
	Acres	Bushels	Bushels	Cents	Dollars
Wisconsin	41,000	12.1	496,100	120	595,320
Minnesota	667,500	10.4	6,942,000	107	7,427,940

The value of the flaxseed crop as compared to the value of other crops raised in the United States in 1902, will be of interest:

Value of flaxseed crop...................	$30,814,661
Value of rye crop........................	17,080,793
Value of buckwheat crop..................	8,654,704
Value of barley crop.....................	61,898,034
Value of tobacco crop....................	57,503,510

Flea-beetles, small leaf-beetles of the tribe *Halticini*, of the family *Chrysomelidæ*, differing from other forms of this family by their extraordinary leaping power due to the enormously developed hind femora. Many of them are injurious to vegetation from their habit of eating the starting leaves full of holes, causing the drying up and death of the plant; hence certain species are known, as «tobacco flea,» "potato flea," "cabbage flea," etc. In their larval state some species live on the root system of various weeds, the adults doing the principal damage to useful plants. Some species are also leaf-miners, while a few feed on the upper surface of leaves like the young of common leaf-beetles, but most species feed on both surfaces. One of the best remedies is bordeaux mixture, doubly efficient when mixed with Paris green and administered in the form of a spray. See LEAF-BEETLES.

Flea-hopper, either of two species of injurious minute black bugs of the family *Capsidæ.* The commonest is the garden flea-hopper (*Halticus uhleri*), which feeds and breeds normally on clover, but attacks all garden vegetables, commonly on the under sides of leaves, which it punctures so as to cause the death of the tissue in small irregular white patches. It somewhat resembles a flea-beetle (q.v.), but is remarkable in being dimorphic, a portion of the females having well-developed wings, the remainder being short-winged. The best remedy is kerosene emulsion as an under spray, and the avoidance of planting susceptible crops after the cutting of clover fields. A related species is known as the false flea-hopper (*Agalliastes associatus*).

Flea-louse, one of the jumping plant-lice of the family *Psyllidæ,* familiarly represented by a pest of the pear-tree (q.v.). Some of the species make galls.

Fleabane. See ERIGERON.

Fleas, minute wingless insects with bodies covered by a strong armor of fine scaly plates and mouth-parts formed for sucking. They constitute the order *Siphonaptera* and are related to the *Diptera.* Everyone is familiar with these troublesome parasites of man and domestic animals, but few persons have studied them sufficiently to know the larval and pupal stages, or to recognize the fact that there are many species. Only recently has it been established that the flea most annoying to human beings in America is not the human flea of the Old World (*Pulex irritans*), but the so-called dog-and-cat flea (*Pulex serraticeps*). Both species are of cosmopolitan distribution, but the former is fortunately extremely rare in this country, while the latter is to be found everywhere. Observations conducted by the United States Department of Agriculture have shown that the development of these insects is hastened by a moist or humid atmosphere. The egg stage is very short, th larvæ, which are worm-like, spin cocoons in which the pupal stage is formed in from 7 to 14 days after hatching and the imago appears five days later, showing that in the warmest weather an entire generation may develop in little more than a fortnight. Fleas will develop successfully in any situation where they are not too much disturbed, as in rugs, mats, or in straw or litter on which cats or dogs have slept; and they are also carried from one place to another by rats and mice and other animals. Dr. C. F. Baker ascertained in 1895 that there were 47 valid species of fleas in the United States; and probably this number might be doubled if all of the parasites of our larger animals were known. While many persons are indifferent to the presence of fleas others suffer severely from their attacks. Very many alleged cases of "hives" have been found to be produced by fleas, and epidemics of fleas in restricted areas as, for example, in several neighboring houses, have been traced to the body of an animal which had died near by The fleas desert the dying body of their host, jump on the clothing of any person passing, and are thus carried from house to house. One means of protection against them consists in avoiding carpets, and keeping the floors painted and covered with rugs, which should be frequently moved, swept and aired. Household pets should be kept out of the house during the summer time; in fact, it is better to exclude cats entirely, because they cannot be washed and freed from parasites so readily as dogs. Rats and mice also carry these and other parasites. The best remedy for those who suffer from fleas is to apply ammonia as strong as can be borne and as soon as possible to the bite, which in some persons is followed by an eruption as big as a dime, attended by severe itching. The free use of baking soda would serve nearly the same purpose where ammonia cannot readily be obtained. Consult: Howard & Marlatt, 'Household Insects of the United States,' issued by the Department of Agriculture.

Fleece Golden, in Grecian mythology, the fleece of gold taken from the ram on which Phrixus and Helle escaped from being sacrificed.

Fleece, Order of the Golden, a military order instituted by Philip the Good, Duke of Burgundy, at Bruges, 10 Jan. 1429, on the occasion of his marriage with the Portuguese princess, Isabella. The order now belongs to both Austria and Spain. See GOLDEN FLEECE, ORDER OF.

Fleet, (1) A tidal stream, so called from the swiftness of its current, which flowed by the walls of old London city; the title is also applied to a creek; an inlet or arm of the sea, as North-fleet, etc. (2) Fleet Street, London, derives its name from the Fleet ditch. (3) The Fleet, or Fleet Prison, an historic prison in London, so called from its being situated by the side of the Fleet ditch. In it were confined persons committed by the ecclesiastical courts and the courts of equity, exchequer, and common pleas. It existed from the 12th century until its abolition in 1846. (4) Fleet books, the original records of the marriages celebrated in the Fleet prison, between 1686 and 1754. (5) Fleet marriages, marriages performed clandestinely and without banns or license by the poor chaplains in the Fleet prison, previous to 1754, when they were declared illegal by the Marriage Act.

Fleet'wood, Charles, English soldier: b. Northamptonshire, England; d. Stoke Newington, London, 4 Oct. 1692. He was of good family, studied law, was elected member of Parliament in 1646, and appointed governor of the Isle of Wight in 1649. He was made lieutenant-general of cavalry in Cromwell's army, distinguished himself at the battle of Worcester (1651) and married Bridget, Henry Ireton's widow, the daughter of Cromwell. He was put in command of the troops in Ireland, where he resided as Lord Deputy until 1655. He was appointed general of Richard Cromwell's army 18 Oct. 1659, but on the promotion of Monk in December 1659, he resigned. After the Restoration he retired to obscurity at Stoke Newington.

Fleetwood, George, English parliamentarian: b. in Buckinghamshire, England; d. in America about 1665. He represented his native shire in the Long Parliament (1647). He signed the death warrant of the king, raised a regiment of horse for Cromwell's army and was by the latter raised to the peerage. By the government of Charles II. he was condemned to death as a regicide, but on changing his allegiance, the sentence was mitigated to confiscation of his estates, and he emigrated to America.

Fleetwood, or **Brandy Station, Battle of.** Gen. Hooker, suspecting that Gen. Lee was gathering his forces on the upper Rappahannock for a movement northward, and informed that Gen. Stuart's Confederate cavalry was at Culpeper Court House, ordered Gen. Pleasonton, who was at Catlett's Station, to cross the Rappahannock at Beverly and Kelly's Fords, attack Stuart, and ascertain Lee's intentions. Pleasonton had the cavalry divisions of Buford and Gregg, and Hooker sent him two picked provisional infantry brigades of 3,000 men, under Gens. Ames and Russell, making in all, cavalry and infantry, an effective force of 10,900 men. Stuart had five brigades of 10,200 men. At daybreak 9 June 1863 Buford, with his cavalry and one brigade of infantry, crossed at Beverly Ford and encountered one of Stuart's brigades, under command of Gen. Sam Jones, and a severe contest ensued, in which the 8th New York cavalry, Col. B. F. Davis, was routed and its commander killed. A charge of the 8th Illinois cavalry drove Jones back two miles, where he joined Stuart and the two brigades of Wade Hampton and W. H. F. Lee. Meantime Gregg, with his cavalry division and an infantry brigade, crossed the river at Kelly's Ford, and pushing back Robertson's brigade, approached Fleetwood Hill from the east, as Buford moved on Brandy Station from the northwest. Fleetwood Hill is a few hundred yards north of Brandy Station, and a hard hand-to-hand struggle ensued at both points, with varying success. Buford held his own near Brandy Station, but Gregg, at Fleetwood Hill, was finally compelled to withdraw, leaving three of his guns in the hands of the enemy. Pleasonton, satisfied that a great part of Lee's army was in his front, recrossed the Rappahannock with about 100 prisoners. The Union loss was 484 killed and wounded and 382 missing. The Confederate loss was 485, of whom 301 were killed or wounded. This engagement marks the beginning of the Gettysburg campaign. Consult: 'Official Records,' Vol. XXVII.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. III.

E. A. CARMAN.

Fleischer, Heinrich Leberecht, hīn'riH lā'be-reHt flī'sher, German Orientalist: b. Schandau, Saxony, 21 Feb. 1801; d. Leipsic 10 Feb. 1888. He was professor of Oriental languages at the University of Leipsic 1836–88. Beside editing Ali's 'Hundred Sayings' (1837), and other works, he wrote a 'Critical Dissertation on Habicht's Glossary to the First Four Volumes of the Thousand and One Nights' (1836); 'Grammar of the Modern Persian Languages' (1875); 'Kleinere Schriften' (1885–8).

Fleming, George. See FLETCHER, JULIA CONSTANCE.

Flem'ing, John Ambrose, English electrical engineer: b. Lancaster, England, 1849. He was educated at the Royal College of Chemistry and St. John's College, Cambridge, and has been associated for many years with the progress of electrical science. He has published: 'Short Lectures to Electrical Artisans' (1885); 'Treatise on the Alternate Current Transformer' (1889–92); 'Electric Lamps and Electric Lighting' (1894); 'Magnets and Electric Currents' (1897); 'Waves and Ripples in Water, Air, and Ether' (1902); etc.

Fleming, May Agnes Early (MRS.), Canadian story-writer: b. New Brunswick 1840; d. 1880. She was a prolific author of romances, mostly sensational, among them being: 'Guy Earlscourt's Wife'; 'Lost for a Woman'; 'Pride and Passion.'

Fleming, or **Flemming, Paul,** powl, German lyric poet: b. Hartenstein, Saxony, 5 Oct. 1609; d. Hamburg 2 April 1640. As an attaché of an embassy to Russia and Persia, he had an opportunity (1635–9) of studying many peoples. His 'German Poems,' which appeared in 1642, has been often republished.

Fleming, Richard, English prelate: b. Yorkshire about 1360; d. 1431. At first a supporter of Wiclif's doctrines he subsequently, when bishop of Lincoln, became staunchly orthodox and is remembered as the prelate who dug up and burned the body of Wiclif and cast the ashes into the Swift. He planned a college at Oxford to be a bulwark against heresy, but the present Lincoln College was, however, not founded till after the bishop's death.

Fleming, SIR Sandford, Canadian engineer: b. Kirkcaldy, Fifeshire, Scotland, 7 Jan. 1827. He went to Canada in 1845 where he constructed the Inter-Colonial Railway through Nova Scotia, New Brunswick and Quebec. He was engineer in chief of the Canadian Pacific Railway 1871–80, and has published: 'The Inter-Colonial: a History, 1832–76'; 'England and Canada'; 'Time and its Notation'; etc. He was knighted in 1897.

Fleming, William Hansell, American Shakespearian scholar: b. Philadelphia, Pa., 23 Aug. 1844. He was educated at Princeton University and has published: 'How to Study Shakespeare' (1897–9), and edited the 'Bankside Shakespeare.'

Flem'ingsburg, Ky., a town and county-seat in Fleming County, on the Covington, F. & A. R.R. Pop. (1900) 1,711.

Flem'ington, a town and county-seat of Hunterdon County, N. J., on the Pennsylvania, the Lehigh Valley, and the Central Railroad of New Jersey, 50 miles west of New York. Pop. (1900) 2,145.

Flemish Art. See FLEMISH SCHOOL.

Flemish Bond, in bricklaying, a particular mode of disposing bricks in a wall, so as to tie and break joints. It consists of a header and stretcher alternately.

Flemish Brick, European brick used for paving; 72 will pave a square yard. They are of a yellowish color, and harder than the ordinary bricks.

Flemish Language and Literature. *Vlämisch* or *Duytsch*, the Low German vernacular spoken by the Vlamingen or Flemings inhabiting the Belgian provinces of East and West Flanders, parts of Holland and the French department of Nord, is akin to the Frisian and to the Hollandish or Dutch which is its younger branch. The latter differs from Flemish in having been reformed and simplified, while Flemish retains the greater part of the archaic features of its 16th century spelling, pronunciation, and words and forms of speech of French and Spanish origin. Since Belgium became an independent kingdom in 1830, a strong desire has been manifested to foster Flemish traditions and to cultivate and promote its language and literature; before that date its history is identified with that of Dutch language and literature. (See HOLLAND.) Among early Flemish literature is the 'Spiegel historical' (historic mirror) of Jacob van Maerlant (1235–1300), a translation of 'Boece' or 'Boethius' by Jacob Velt of Bruges in the 15th century, and the 'Hive of the Catholic Church,' by Philip van Marnix (1569). The modern movement to rehabilitate the vernacular was largely due to the efforts of Jan Frans Willem who before the separation of Belgium from Holland had strenuously advocated its use as a literary language. With the able co-operation of such authors as Van Ryswyck, Ledeganck, Rense, Van Duyse, Blieck, Serrure, David Conscience and others, the movement made great progress, received official support, and was crowned with success in 1886 when the Koninklije Vlaamsche Akademie (Royal Flemish Academy) was founded and the use of Flemish, as well as French, was adopted as the legal and official language of the kingdom. Prominent amid modern Flemish literature is the verse of Ledeganck: 'De drie Zustersteden,' 'De Hut in 't Wowd,' etc.; of Ryswyck, 'Antigonus,' 'Eppenstein,' and 'Oorspronkelikje Verhalen'; of Van Beers, 'Begga,' 'Levensbeelden' and 'Gevoel en Leven.' Among works of fiction are Hendrick Conscience's 'Artevelde'; Delcroix's 'Geld of Liefde' and 'Philippine van Vlaanderen'; Sleeckx's 'In 't Schipperskwatier' and 'Dirk Meyer'; and Sneiders' 'De gasthuisnon.' Other well-known novelists are Bergmann, Madame Courtmans, and the two poetesses, Rosalie and Virginie Loveling, poets also including Dantzenberg, De Cort, and Van Droogerbroeck. Representative drama is Sleeckx's 'Meester en Knecht,' and 'Zannekin.' Consult: Willems, 'Sur la langue et la littérature neerlandaises, par rapport aux provinces méridionales des Pays-Bas' (1818); Vercoullie, 'Spraakleer van het Westvlaamsch' (1894); Hamelius, 'Histoire politique et littéraire du mouvement flamand' (1894).

Flemish School, a school of painting which originated in Flanders in the early part of the 15th century, with the invention, or at least the first practice, of painting in oil. It has been generally attributed to Jan Van Eyck, who was accustomed to varnish his distemper pictures with a composition of oils. In course of practice he came to mix his colors with oil instead of water, which rendered them brilliant without the trouble of varnishing. From this and subsequent experiments arose the art of painting in oil. The chief early masters of the school were Jan Van Eyck and his brother and sister, Hubert and Margarete, Matsys, Mabuse, Memling, Weyden, and Moro; to the second period belong Rubens, VanDyck, Snyders, Jordaens and the younger Teniers.

Flensburg, flens'boorg, Prussia, a town in the province of Schleswig-Holstein, 20 miles from the town of Schleswig. It was a place of importance as early as the 12th century, but subsequently suffered much from wars and conflagrations. It is again prosperous, and is now the most important town in Schleswig. The industrial establishments include ship-building yards, sugar-refineries, tobacco-factories, soap-works, foundries, breweries, distilleries, etc. In 1866 it fell to Prussia, along with the duchy of Schleswig-Holstein. Pop. (1901) 48,992.

Flesh (or muscle) is composed of the proteids, myosin, musclin, myoglobulin, and myo-albumin, together with varying amounts of fats, salts, and nitrogenous extractive substances. Of the three classes of foodstuffs needed in the human economy, meat supplies most of the proteid and fat, while the vegetable kingdom supplies the carbohydrates. The proteids are more properly the tissue-building elements, while the fats and carbohydrates are more readily oxidizable, and supply the body with energy. Proteids must be taken as such, since the human economy cannot cause conversion of the other sorts of food into proteids. The minimum of these various substances for the proper preservation of life has not been positively determined, but approximately the average healthy man requires 100 grams of fat, 400 grams of carbohydrate, and 100 grams of proteid per diem. The necessary amount of proteid material can be obtained from the vegetable kingdom, and there is no doubt that some systems are better suited for this diet; but to the large majority of individuals a mixed diet, containing a certain amount of meat, is more readily taken care of. The meat proteids are usually more quickly and completely digested.

The nitrogenous extractive substances, ceratine, the xanthin bases, and the like, are also of value to the system because of their power of exciting gastric secretions and stimulating circulation. The various meat extracts contain a large proportion of these substances, and most of them have little else. An overabundance of meat very frequently causes a nervous, irritable condition. This is less true of the so-called white meats, a difference not to be explained on the ground that the white meats contain less of the extractives, since the opposite is the case. As a general rule the diet of the well-to-do in America is entirely too high in food-value, but particularly in the amount of albuminous foods. These constant errors find their expression in the well-nigh universal complaint of dyspepsia and so-called uric-acid disturbances. Such intoxications are almost sure to follow if more animal food is taken than can be digested and absorbed. Putrefaction of the unabsorbed food takes place, with generation of toxic substances and absorption of them into the general circulation.

Flesh-fly, any of a large group of showy flies (family *Sarcophagidæ*), the more familiar and typical members of which breed in decaying flesh. Some, however, pass their larval stages in dung, or decaying vegetables, or are parasitic in the wounds and sores of animals and man. Most of them look like large house-flies, sometimes bright with metallic blue or green, or gray with black stripes: common names are "blue-bottle" (for *Lucilia cæsar,* which often comes into houses in stormy weather), or "green-bottle," for the "blow-flies" (q.v.) of the genus *Calliphora.* The common flesh-fly of Europe (*Sarcophaga carnaria*) is a pest that does not appear in the United States, but we have a very similar and equally troublesome species in *S. sarraceniæ.* The directness with which these flies find and utilize a piece of decayed meat, for the deposit of their eggs, or their living maggots, avoiding fresh meat equally accessible, is regarded as an evidence that they are under the control of an impulse of a chemical character rather than merely following a sense of smell.

Fleshly School, The. See DECADENTS.

Fletch'er, Alice Cunningham, American ethnologist: b. Boston, Mass., 1845. She is the originator of the scheme by which loans are made to Indians in order that they may buy lands and build houses. She is now employed in the management of the Peabody Museum of American Archæology and Ethnology, and is the author of 'Indian Story and Song from North America' (1900).

Fletcher, Andrew, of Saltoun, Scottish political writer and patriot: b. Saltoun, Haddingtonshire, 1655; d. London, September 1716. Having distinguished himself in opposition to the court he deemed it prudent to retire to Holland; and on his non-appearance to a summons from the lords in council he was outlawed. In 1685 he joined the enterprise of the Duke of Monmouth. He subsequently joined the Scottish refugees in Holland, and when the revolution of 1688 took place returned to England with William of Orange, resumed possession of his estate, and became a member of the convention for settling the new government in Scotland. In 1698 he printed 'A Discourse on Government in Relation to Militias'; and also, 'Two Discourses Concerning the Affairs of Scotland.' His tracts and some of his speeches appeared in one volume, entitled: 'The Political Works of Andrew Fletcher, Esq.' (1737). Consult Omond, 'Fletcher of Saltoun' (1897).

Fletcher, Benjamin, English colonial governor. He was appointed by William and Mary in 1692, after serving during the war in the Low Countries, as well as in Ireland. When William Penn was for a time deprived of his proprietary rights he acted as governor in Pennsylvania (1693–4). He was at last forced to resign from his post in New York, and many charges were made against him. Consult: Wilson, 'Memorial History of the City of New York' (1892).

Fletcher, Giles, English poet: b. Watford, Hertfordshire, about 1549; d. London March 1611. He was ambassador to Russia in 1588, but his description of that country, 'Of the Russe Common Wealth,' appearing in 1591, was suppressed. It was reprinted for the Hakluyt Society 1856. He also wrote: 'Licia: Poems of Love' (1593).

Fletcher, Giles, English poet: b. about 1588; d. 1623. He was a son of Giles Fletcher the elder, and wrote the poem, 'Christ's Victory' (1610). A new edition appeared in 1824.

Fletcher, James Cooley, American clergyman and author: b. Indianapolis, Ind., 1823. Between 1851 and 1865 he traveled widely as a missionary in Brazil, and was at one time secretary to the United States legation at Rio de Janeiro. In 1869–73 he was consul at Oporto, Portugal, later was a missionary in Naples, Italy, and from 1877 was resident at Indianapolis. His 'Brazil and the Brazilians,' early editions of which contain the name of D. P. Kidder as associate author, was long the authoritative English work on the subject.

Fletcher, John. See BEAUMONT, FRANCIS, AND FLETCHER, JOHN.

Fletcher, Joseph Smith, English journalist and novelist: b. Halifax, Yorkshire, 1863. He has written extensively for newspapers under the pseudonym "A SON OF THE SOIL," as well as novels and collections of short stories which have been very popular, and several of which have been widely read in the United States. His published books include: 'Anima Christi' (1884); 'When Charles the First was King' (1892); 'Poems' (1892); 'The Quarry Farm' (1893); 'The Wonderful Wapentake' (1894); 'Where Highways Cross' (1895); 'Mistress Spitfire' (1896); 'Ballads of Revolt' (1896); 'Life in Arcadia' (1896); 'At the Gate of the Fold' (1896); 'God's Failures' (1897); 'The Making of Matthias' (1897); 'The Builders' (1897); 'The Paths of the Prudent' (1899); 'From the Broad Acres' (1899); 'Morrison's Machine' (1900); 'The Harvesters' (1900); 'A Picturesque History of Yorkshire' (1899–1900); 'The Three Days' Terror'; 'The Golden Spur' (1901); 'Bonds of Steel'; 'The Investigators' (1902); 'In the Days of Drake'; 'At the Blue Bell Inn.'

Fletcher, Julia Constance (pseudonym "GEORGE FLEMING"), American novelist; b. Rio Janeiro, Brazil, 1858. She is a daughter of James Cooley Fletcher (q.v.). She has resided for years in Italy and in London. Her novels are: 'Kismet' (1877); 'Mirage' (1878); 'The Head of the Medusa' (1880); 'Andromeda' (1885); 'The Truth about Clement Ker' (1889); 'For Plain Women Only' (1895); and 'Little Stories about Women' (1897). She has also written the plays: 'Mrs. Lessingham' (1894); 'A Man and His Wife' (1897); 'The Canary' (1899); 'The Fantasticks' (1900).

Fletcher, Lazarus, English mineralogist: b. Salford, England, 3 March 1854. He was educated at Balliol College, Oxford, and has been keeper of minerals in the British Museum from 1880. He has published: 'Introduction to the Study of Meteorites' (1881); 'Introduction to the Study of Minerals' (1884); 'The Optical Indicatrix' (1892); 'Introduction to the Study of Rocks' (1895).

Fletcher, Phineas, English poet: b. Cranbrook, Kent, April 1582; d. about 1650. He was a son of Giles Fletcher the elder and a cousin of John Fletcher (q.v.). He was the author of 'Sicilides,' a pastoral drama (1614); 'The Purple Island and Piscatory Eclogues' (1633). 'The Purple Island' is an allegorical description of man, founded upon an allegory in the ninth canto of the second book of the 'Faerie Queene.' It is composed in the Spenserian manner, and is not without passages of strong fancy and beauty of description. In the first five cantos, however, the reader loses the poet in the anatomist — a character but little adapted to the handling of poetry. When, however, he steps from the physical to the intellectual man, he not only attracts, but secures attention by a profusion of images, many of which are distinguished by much boldness of conception and brilliancy of coloring. The ‹Piscatory Eclogues› have considerable sweetness of versification, and much descriptive elegance. Milton was indebted to both Phineas and his brother Giles for different passages of the ‹Paradise Lost› and ‹Paradise Regained.›

Fletcher, Robert, American surgeon: b. Bristol, England, 1823. He was graduated at the Royal College of Surgeons 1841; came to the United States, and was surgeon of an Ohio regiment during the Civil War. He afterward became principal assistant librarian of the surgeon-general's office at Washington, D. C., and professor of medical jurisprudence in the Columbian University. He has published: ‹Paul Broca and the French School of Anthropology› (1882); ‹Human Proportion in Art and Anthropometry› (1883); ‹The New School of Criminal Anthropology› (1891); ‹Scopelism› (1897).

Fletcher, Robert Howe, American soldier and author: b. Cincinnati, Ohio, 21 July 1850. He entered the United States Naval Academy at 17, and at graduation was transferred to the army where he served on the Indian frontier and in California till 1886. Since 1898 he has been curator of the Mark Hopkins Institute of Art at San Francisco. He has published: ‹A Blind Bargain›; ‹The Johnstown Stage›; ‹Marjorie and Her Papa.›

Fletcher, William Isaac, American librarian: b. Burlington, Vt., 28 April 1844. He has been librarian of Amherst College from 1883 and is the author of ‹Public Libraries in America› (1895); and was joint editor of ‹Poole's Index to Periodical Literature.› He has also edited continuations of the latter (1882–1900); the ‹A. L. A. Index to General Literature› (1893); and the ‹Co-operative Index to Periodicals› (1883–91).

Fleur-de-lis, fler-de-lē, an heraldic emblem probably derived from the iris-plant. Some of the great families of France (most of whom are now extinct) bore the emblem on their shields from the very commencement of the practice of blazoning, and a large number of families in Germany, Sweden, Switzerland, and other parts of Europe have borne the fleurs-de-lis on their coats of arms from the 12th century. The great popularity of this emblem in France dates from the 13th century. The royal coat of arms of France consisted of three golden lilies on a blue ground, with the device, ‹*Lilia neque nent neque laborant.*› The shield of France was anciently, in heraldic language, *semé de fleurs-de-lis*, that is, bore this emblem scattered over the shield. It is commonly believed that it was Charles V. (1364–80) who reduced the number to three; but this is disproved by the fact that two seals have been preserved, the one belonging to Philip the Fair (1285–1314), the other belonging to Philip of Valois (1328–50), both of which bear three fleurs-de-lis; and the town library of Rouen contains a collection of charts relating to the celebrated abbey of Savigny, to one of which, bearing the date 1212, a seal is attached, which is still in a state of perfect preservation, representing three fleurs-de-lis exactly similar to those used on the shield of France. Hence it appears that the use of this emblem in a triple form is much more ancient than is usually thought. See HERALDRY.

Fleurus, fle-rüs, a town in Belgium, province of Hainaut, seven miles northeast of Charleroi. It has manufactures of coarse woolens and flax, with some tanneries and salt-works, and a trade in agricultural produce. In the vicinity, in August 1622, the Spaniards under Gonzales defeated the army commanded by Ernst von Mansfield; 1 July 1690, the French under Marshal Luxembourg defeated the Germans under Prince Waldeck; and 26 June 1794, the French republican forces under Marshal Jourdan defeated the Austrian army. The battle of Ligny, also, is sometimes known as the battle of Fleurus, Ligny being only about two miles from Fleurus. Pop. (1901) 6,264.

Fleury, Andre, Hercule de, än-drā ar-cül de fle-rē, a cardinal and prime minister of France under Louis XV.: b. Lodève, Languedoc, France, in 1653; d. 29 Jan. 1743. Coming to court, he won general favor by his pleasing person and fine understanding; became bishop of Fréjus; and, through the interest of Madame Maintenon, was appointed instructor to Louis XV. In 1726 he was made cardinal, placed at the head of the ministry, and from his 73d to his 90th year he administered the affairs of his country with great success.

Fleury, Claude, clōd, French Church historian: b. Paris, France, 6 Dec. 1640; d. there 14 July 1723. His learning and unaffected simplicity made him a notable figure at the court of Louis XIV., and later at that of Louis XV., whose confessor he became. An ‹Ecclesiastical History› (1691–1720) forms his claim to enduring renown; the work coming down to 1414, at which point a later writer has attempted, though not sympathetically, to round out the master's performance. ‹A History of French Law› (1674) and a ‹Historical Catechism› (1679) are less important achievements.

Fleury, Maurice de, mō-rēs de, French physician: b. Bordeaux 1860. He studied under his father at Bordeaux, and practised in the hospitals there and at Paris. His specialties are nervous complaints and the physical and intellectual training of children, so as to produce a sound mind in a sound body. He has published many valuable contributions to the subjects of his special study. Such are: ‹Contribution à l'étude de l'hysterie senile› (1890); ‹Traitement rationnel de la neurasthénie› (1894); ‹Pathogénie de l'épuisement nerveux› (1896); ‹Introduction à la médecine de l'esprit› (1897); ‹L'âme du criminel› (1899); and ‹Le corps et l'âme de l'enfant› (1899).

Fleury-Husson, Jules. See CHAMPFLEURY.

Flexibility, in physics, the property which all bodies possess to a greater or less degree, and which is evinced in their disposition to yield or change their form in a direction at right angles to their length, through their own weight or by means of any pressure or strain applied to them. Pieces of the same material differ from each other in the degree of flexibility they exhibit in proportion to their length and thickness. See PHYSICS.

Flexner, Simon, American pathologist: b. Louisville, Ky., 25 March 1863. He was graduated from its University of Louisville as M. D. in 1889. He then became a post-graduate student at Johns Hopkins University and subsequently pursued his pathological studies at the University of Strasburg. He was professor of pathology, Johns Hopkins University 1891–8; and of pathological anatomy 1898–9, and has been professor of pathology in the University of Pennsylvania since the year last named. He was also director of Ayer Chemical Laboratory, Pennsylvania Hospital, 1901–3; and pathologist of University Hospital and Philadelphia Hospital 1899–1903. His ability was further recognized by his being chosen in 1902 director of the Rockefeller Laboratory of Research in New York, established to promote the study of the origin of disease. Among his publications are: 'The Pathology of Tox-Albumin Intoxication'; 'Micro-organisms'; 'The Bacillus Pyogenes Filiformis'; 'The Aetiology of Dysentery'; 'Terminal Infections'; 'Experimental Pancreatitis'; 'The Nature of Snake Venoms,' and many other papers and monographs relating to bacteriological and pathological subjects.

Flexure, in mechanics, is a species of strain in which a solid body is distorted so that certain of its original planes become converted into cylindrical or conical surfaces. The term is most commonly used in connection with beams, where it signifies the elastic yield of the beam under the influence of its load. When a beam is supported at both ends and loaded in the middle, it sags in such a manner that its originally straight longitudinal fibres become curved into approximately circular arcs. The radius of these arcs is very large, of course, in practical construction, where the beams are composed of steel or wood. In a beam that is supported and loaded as described above, the upper fibres of the beam are in compression, and the lower ones in tension. The compressive strains in the upper parts, and the tensile strains in the lower parts, decrease toward the middle of the beam, and somewhere about the middle there is a surface (called the "neutral surface," or "neutral axis"), on which there is neither tension nor compression. The flexure of such a beam is measured by the depression of its centre under the influence of the load; this depression being directly proportional to the product of the load by the cube of the length of the beam between supports, and inversely proportional to the continued product of the horizontal thickness of the beam, multiplied by the cube of its vertical depth, and again by the value of Young's modulus for the material of which the beam is made. (See ELASTICITY; STRENGTH OF MATERIALS.) Consult also, Rankine, 'Useful Rules and Tables.'

Flick, Lawrence F., American pathologist: b. Carroll Township, Cambria County, Pa., 10 Aug. 1856. He was educated at the Benedictine College near Latrobe, Pa., and was graduated in medicine at Jefferson Medical College, Philadelphia, in 1879. He took up tuberculosis as a specialty and early in his career began a movement for the prevention of this disease. In June 1888, he read a paper upon the contagiousness of phthisis before the Medical Society of the State of Pennsylvania, showing that houses which had been occupied by consumptives gave the disease to subsequent occupants, and that the malady was essentially a contact disease. He subsequently published many monographs upon this topic, and 1890 started a movement for the establishment of consumption hospitals which culminated in the founding of the Rush Hospital for diseases of the chest. In 1892 he founded the Pennsylvania Society for the Prevention of Tuberculosis, of which he was president for some years. In 1895 he helped to found the Free Hospital for Poor Consumptives and was elected its president. In 1903 he was entrusted with the establishment of the Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis and was appointed its medical director.

Flick'el, Paul, powl, German artist: b. Berlin 8 April 1852. He studied three years in the Art School at Weimar, and in 1874 went to Düsseldorf and in a year began his career as a landscape painter. He traveled for the sake of studying art in Germany and Austria. In 1877 he continued his wandering in Italy and on the spot painted many pictures, such as 'The View of Naples from Capo di Monte'; 'Garden at Monte Carlo'; 'Fountain of the Villa Borghese,' scenes in which he showed a skilful management of bright sunlight effect, and complete mastery in handling the luxuriant vegetation of the south. His pictures of mountain forest scenery in Austria attracted notice and his 'Beech Forest,' which was based on studies made near Prerau, Moravia, gained for him the "Great Gold Medal" at the Berlin exhibition of 1886.

Flicker, one of the many local names of the North American golden-winged woodpecker (*Colaptes auratus*). This name, derived from one of the bird's characteristic calls, is coming into far more general use than formerly. A description of the bird will be found under WOODPECKER.

Flick'inger, Daniel Kumler, American bishop of the denomination of United Brethren: b. Sevenmile, Ohio, 25 May 1824. In 1857-85 he was corresponding secretary of the United Brethren Missionary Society, in 1885 became foreign missionary bishop, and in that capacity made 12 journeys in Africa. His publications, besides a volume of sermons, include: 'Off-Hand Sketches in Africa'; 'Ethiopia'; 'The Church's Marching Orders'; 'Our Missionary Work.'

Fliedner, Theodor, tā'ō-dōr flēd'nĕr, German Lutheran clergyman: b. Eppstein, Nassau, Germany, 21 Jan. 1800; d. Kaiserswerth 4 Oct. 1864. He became pastor in Kaiserswerth 1822. He gradually amassed in this poor parish an endowment fund for a church, school and poorhouse. In 1833 he founded an asylum for released female convicts, and in 1835 an infant school, at Düsseldorf, the earliest in Germany; a similar institution was organized by him at Kaiserswerth, the year following. In the same year he founded the Deaconesses' association, which was his greatest and most notable work. Among his writings, which are principally devotional and educational, may be mentioned 'Das Buch der Martyrer.'

Flies, two-winged insects of the order *Diptera* (q.v.), whose larvæ are legless, soft, and eruciform, and are termed "maggots." The group is world-wide in its distribution, and probably quite as numerous as either the beetles, or the group of wasps, bees, ants, etc. It is now known to contain about 40,000 species, most of which are incalculably numerous in individuals; so that "swarms" of flies is a proverbial expression. Entomologists believe that 8 or 10 times 40,000 species really exist. This vast abundance is due to the plenitude of their food, and to their fecundity; and it is accompanied by a very high state of organization, so that certain families of flies are held by some students to stand at the head of the insect tribe in specialization of structure. Intellectually, however, they are far behind the *Hymenoptera;* and to this fact, to the small size and unattractive appearance of most specimens (although great brilliance of color is to be found among some families), and to the comparatively uniform and uninteresting nature of their metamorphoses, are to be charged the relatively small amount of study that has been given to the group. The life-history of the ordinary flies is detailed below; but many peculiarities exist in other families of the order. "With some," says Howard, "no eggs are laid, and living larvæ issue from the body of the female. Such flies then become practically viviparous or 'larviparous.' With others, although these are few in number, the development within the body of the female goes even farther, and when the insect emerges from the body of its mother it is already in the pupal condition. Such forms are called 'pupiparous.' . . . Many species — comprising, in fact, whole families — are aquatic or subaquatic in their early stages, and some possess the faculty of living under what appear to be most disadvantageous conditions." Some of the flies of the family *Ephydridæ* (whose eggs or larvæ are eaten by American Indians,— see AHUATLE; KOO-CHAH-BEE) live in the strongly alkaline lakes of the Far West where little else can exist.

Flies are mainly day-flies, and fond of sunshine, but some appear only at night or in the dusk; a section of the tribe does not fly at all, being wingless and parasitic. They live in the most diverse manner; some attack large animals and suck their blood; some prey on smaller insects; some suck honey, and in search of it take part in the cross-fertilization of flowers (see FLOWERS AND INSECTS); and many find their food in decaying animal and vegetable matter. A large number of dipterous larvæ eat refuse or carrion,— whence arise serious evils to mankind,— others feed inside growing vegetables; and some maggots prey, or are parasitic upon, other animals.

A type of the group is found in the house-fly (*Musca domestica*), which represents the great family *Muscidæ*, in which most of the familiar flies about houses and stables are included, and its life-history represents that of its kind generally. Its eggs are laid preferably on horse-manure, but also on human or other excrement, decaying vegetables, etc., and hatch in six or eight hours, producing white maggots. These mature in four or five days, when their skins harden and turn brown, forming a puparium, or case, within which the true pupa forms, and five days later gives birth to a perfected fly. Thus a total life cycle requires in midsummer only about 10 days, and a dozen generations may thus be born in warm climates within a single season. As each fly deposits on the average 120 eggs, and as the maggots of 1,200 house-flies may be sustained by a pound of manure, the possible rapidity of their multiplication is apparent. Most flies live but a few weeks, and toward the end of the season they die with great rapidity, becoming infested with reddish mites, which suck their juices, or with fatal fungous diseases (see FUNGI). In warm houses a few may survive a winter, but as a rule all adult flies die in the fall, and the species survives and recovers in the spring from the eggs or pupa left over winter in the manure-heap or other feeding-place. It is plain that attempts to mitigate the annoyance and danger resulting from many flies may best be directed toward the destruction of their eggs and young. That such destruction is desirable and the duty of society is plain when one considers the vast amount of injury these insects may do. Many sorts attack vegetables and fruit, for example the hessian-fly, which is perhaps the most destructive insect in the United States, the apple-fly, the gall-flies, fruit-midges, potato-scab gnat, and others. Others harm domestic animals, as the bot-flies, sheep-ticks, horn-flies, tsetse, and all the horse-flies, bee-killing robber-flies and bee-flies, black-flies, mosquitoes, and many more. This catalogue of harmfulness (to which can be opposed only the beneficial work done by the tachina-flies which cause the death, by parasitism, of other kinds of injurious insects) becomes of small importance, however, beside the enormous evil flies do in spreading virulent diseases from man to man and place to place. Were this not so it might be true, as formerly alleged, that their services as scavengers, as parasites, and in the cross-fertilization of plants, balanced the damage caused by some, and left something to their credit.

Flies as Carriers of Disease.— Consideration of the habits of house-flies and their relatives will show how prone they are to feed upon excrementitious matter, and to be attracted to any decaying or purulent substance. When this is the product of wounds, sores or diseased bodies it is likely to contain the germs of disease; and these may be sucked into the blood or cling to the body of the insect. If, then, the fly alights upon a human being or a susceptible animal, and punctures the skin with its sucking proboscis (for ordinary flies do not "bite," properly speaking), it is likely to leave in the puncture some of the germs it has fed upon, and so infect the person with the disease to which they give rise. Wounds may thus be inoculated with "blood-poison"; and certain diseases, grouped as "myiasis" may arise from taking into the stomach, in eating spoiled vegetables, minute flies (*Anthomyia*) breeding in them. Even vegetable diseases may be so transmitted, as is the case with the "scab" of potatoes, which, according to Hopkins, is spread from plant to plant by the visits of a fungus-gnat (*Epidapus scabiei*).

That this theoretical transmission of disease actually occurred has been demonstrated since the latter part of the 19th century by observation and experiment. It was first ascertained of certain mosquitoes, whose responsibility for much if not all of the malaria from which men suffer was shown. This may be found more fully treated under Mosquitoes (q.v.), where the agency of these small ubiquitous flies in spread-

REPRESENTATIVE FLIES.

ing other diseases is also shown. Dr. Joseph Leidy attributed the spread of gangrene in the hospitals at Washington during the Civil War to the flies; a few years later it was shown that gad-flies which had settled upon the dung of cattle afflicted with anthrax would communicate the disease to healthy kine. In 1888 an Italian investigator showed that flies fed upon a bacillus culture would drop virulent bacilli in their ordure, capable of infecting new cultures; further experiments in India showed that flies fed with a culture of the bacilli of bubonic plague and of Asiatic cholera survived and conveyed the plague to man. An English physician asserted that typhoid fever was spread by insects; and this was abundantly proved during the prevalence of that disease in the military camps during the Spanish-American war of 1898. Flies which have access to the excreta of patients and afterward alight upon food, so infect the food that whoever eats it is in danger of falling ill with the fever. Howard demonstrated that the common house-fly was the principal agent in this transmission. Subsequent investigations showed that the danger of the propagation by flies (and other household insects) was equally great in diphtheria and yellow fever. In another series of cases, as among mosquitoes, the fly acts as intermediary host for disease germs which develop in its blood to the point where they are virulent when introduced into the circulation of man or beast. Such is the case with the African tsetse fly (q.v.), which transmits a greatly dreaded cattle-disease. The purulent ophthalmia, known as «pink-eye,» and particularly prevalent in the South, is facilitated by minute gnats of the genus *Hippelates*.

Dr. L. O. Howard, of the United States Department of Agriculture, has given special attention to this matter, and has found that no less than 77 species of flies frequent human excrement and are therefore liable to obtain and carry disease germs. As the innumerable insects themselves are beyond reach, the measures for protection must be preventive. Dr. Howard says that in order to avoid epidemics of typhoid fever it is necessary to abolish the box privy, prevalent in rural and village districts, and substitute earth-closets, where water-closets cannot be installed; to place stable manure in receptacles and treat it with chloride of lime to destroy the maggots, throwing a shovelful over each day's addition. Pantries, dining-rooms and kitchens should be carefully screened to keep out flies; and especial pains taken in summer to keep flies out of sick-rooms. Detailed instructions and the reasons for them are given by Howard in his pamphlet, ‘How Insects Affect Health in Rural Districts,’ issued as Farmers' Bulletin 155, by the United States Department of Agriculture.

Classification.— The classification of the *Diptera* has proved difficult. An early division was based on the structure of the antennæ: *Nemocera* — those having the antenna thread-like and with 6 to 36 joints; and *Brachycera,* those with the antenna three-jointed and bristle-like. A later and more widely accepted subdivision was based upon the way the pupa-case splits on emergence of the fly; in the *Orthorapha,* the pupæ escape from the larval skin through a T-shaped orifice; in the *Cyclorapha* the pupæ escape through a circular opening at the anterior end. American entomologists, following the special investigations of D. W. Coquillet, now usually divide the order into two sub-orders based upon the character of the mouth-parts, and characterized as follows:

Sub-order Proboscidea.— Antennæ conspicuous, inserted at upper end of the face, sometimes many-jointed, proboscis usually furnished with terminal lips, body rather soft and brittle, legs approximated, wings usually present and frequently furnished with a discal cell; adults oviparous or larviparous, never in all their stages living externally on mammals, birds, or honey-bees.

In this group are placed, in order, the following important families: *Tipulidæ* (crane-flies), *Culicidæ* (mosquitoes), *Cecidomyiidæ* (gall-gnats), *Mycetophilidæ* (fungus-gnats), *Simuliidæ* (black-flies), *Leptidæ* (snipe-flies), *Stratiomyiidæ* (soldier-flies), *Tabanidæ* (horse-flies), *Bombyliidæ* (bee-flies), *Asilidæ* (robber-flies), *Syrphidæ* (syrphus-flies), *Œstridæ* (bot-flies), *Tachinidæ* (tachina-flies), *Sarcophagidæ* (flesh-flies), *Muscidæ* (house-flies), *Anthomyiidæ* (fruit-flies), *Trypetidæ* (fruit-flies), *Ephydridæ* (edible salt-water flies), and *Oscinidæ* (grass-stem flies); besides various less important ones. Each is more particularly described elsewhere in this work.

Sub-order Eproboscidea.— Antennæ usually inconspicuous, commonly inserted near the middle of the sides of the face, and composed of from one to three joints, the apex furnished with a style or bearing several long bristly hairs, proboscis never furnished with terminal lips, body integument tough and leathery, legs on one side of the body usually widely separated from those on the other side, wings, when present, never furnished with a discal cell; adults pupiparous, living externally upon mammals, birds or honey-bees.

This second sub-order comprises only two families, the parasitic bird-ticks (*Hippoboscidæ*) and the bat-ticks (*Nycteribidiidæ*), which owe their vernacular names to their resemblance to true ticks in appearance and habits.

Bibliography.— L. O. Howard's ‘Insect Book’ (New York 1901) contains the latest and most fully illustrated general account of the flies, and also a large list of books on the subject, especially those relating to systematic description. S. W. Williston has an excellent illustrated account in ‘The Standard Natural History,’ Vol. II. His ‘Manual of American Diptera’ (New Haven 1896); Comstock's ‘Manual for the Study of Insects’ (Ithaca, N. Y., 1895); Packard's ‘Half Hours with Insects,’ and ‘Text-Book of Entomology’; and Miall's ‘Natural History of Aquatic Insects’ (1895), may be consulted with profit.

Flight. Flight, strictly speaking, is progress through the air in any desired direction by an agent or object heavier than the air, as opposed to the floating of an object lighter than the air, such as a balloon. Animals accomplish flight mainly by means of wings, which may be special organs as in the insects, or modified fore legs, as in the case of bats and birds. The wings of insects are always thin membranes supported by a stiffer framework. In bats they consist of extensible membranes stretched over the immensely elongated fingers and joined also to the sides of the body and the hind legs. The wings of birds are composed of long stiffened feathers attached to the rudimentary fingers and to the bones of the forearm; the individual feathers overlapping one another so as to form a continuous more or less arched surface. The tail feathers constitute another sail area which plays an important part in flight, while in many bats a continuation of the flight-membrane between the hind legs has much the same function.

Besides these special organs the structure of aërial creatures is modified in many other respects with a view to facilitating flight. Thus the hollow bones of birds are lighter than the solid bones of terrestrial animals and relieve birds of much unnecessary weight; while the general shape of the bird's body and the smooth rounded contour of its feather covering are calculated to give the least possible resistance to the air during flight. Birds are also provided with large distensible air sacs under the skin, the function of which has been a matter of much dispute, but which, as suggested by von Leudenfeld, may aid in shifting the centre of gravity of the body, a matter of the utmost importance to the bird in holding to its course or in turning in flight. The centre of gravity, we may note, is also kept well below the plane of the wings by the distribution of the heavy parts of the body on the pectoral side. So that as the bird flies the heavy breast muscles, which constitute the bulk of its weight, are well down while the wings are attached to the back of the thorax. Thus the body becomes essentially a weight hung directly below an outstretched sail area.

So much for the general structure of flying creatures. Turning now to the principles of flight we have as the main agencies (1) the muscular propulsion on the part of the bird; (2) the support offered to the "sail area" by the air; (3) the force of the wind both in raising and in propelling the bird. Mechanical and physical problems are involved in the study of flight which it will be impossible to consider here, but one or two principles may be mentioned which are of fundamental importance, and the application of which may be seen in all forms of flight. We know that the resistance (that is, support) of the air to a flat surface is greatly increased when the surface is traveling rapidly through the air in its own plane, and it follows that when a bird is once on the wing the buoyancy of the air relative to it is greatly heightened; and having gained a certain momentum it will be possible for the bird to sail some distance without loss of altitude. Again when a flat surface is sailing diagonally through the air the maximum pressure (that is, support) of the air is not under the centre of the surface, but under the forward edge. It is on this principle that we find a tendency to force up the anterior edge of the wings of a sailing bird and in order to counteract it the bird is compelled to shift the centre of gravity of its body farther forward. To do this it may draw the wings back, spread the tail or perhaps extend the head and neck. On the same principle to turn the direction of flight it is merely necessary to flex or raise one wing or one side of the tail. Flight proper may be of two sorts, (1) by flapping the wings, and (2) by soaring. The former is the most familiar and is practised by all birds, while the latter is possible only for birds of large expanse of wing, such as vultures, eagles, gulls, etc.

In taking flight it is very important for the bird to "get a start," as we say; that is, to acquire some relative velocity, and to accomplish this we often see birds which are about to fly run along the ground for a few steps or flap along the surface of the water, while starting head toward the wind with wings properly spread accomplishes the same result. Rising into still air by flapping is very laborious work and some heavy-bodied birds, as the loons, for instance, are utterly unable to take flight when confined within a small area.

When once in the air and fairly started in flight the wing action is far less laborious than at the start, and the upward stroke is often relative to the body only and not necessarily a muscular effort. When this stroke is active, the individual feathers, as instantaneous photographs show us, are more or less separated to reduce the resistance of the air on the recovery. Most birds mingle flapping and straight sailing in various ways, and when once on the wing flight is mainly a matter of presenting their sail area to the air currents in such a way as to gain the greatest benefit from them.

Soaring is flight in circles with set wings and without any visible muscular action on the part of the bird. In spite of this the bird is able to mount higher and higher in the air, gaining impetus enough on the flight with the wind to carry it above its initial altitude when returning on the other half of the circle against the wind. Many theories have been advanced to explain the "soaring bird," some of them purely fantastic, but the true solution of the problem seems still to be lacking. Suffice it to say that this method of flight is possible only in the presence of currents of air, and that the unequal velocity of air at different altitudes doubtless has much to do with it.

Aëronauts naturally look to birds for suggestions in artificial flight, and the great superiority which they exhibit over the best flying machine so far constructed may be seen in Prof. Langly's comparison of his aërodrome which has repeatedly flown from a half to three quarters of a mile, with a condor. The machine with a weight of 30 pounds and a supporting area of 54 square feet is driven by an engine of one and a half horsepower, while the bird weighing 17 pounds has a sail area of only 9.85 square feet and a propelling power of but .043 horsepower. Birds vary very much in wing power according to their method of flight; the humming-bird and pigeon being abundantly supplied with wing muscles to maintain their rapid strokes, while the frigate-bird, a notorious "sailer," is remarkably weak in muscular development. The speed of flying birds also varies greatly. The best flyers of which we have definite record are the carrier pigeons, which travel from 30 to 50 miles an hour, while an albatross, caught and tagged by sailors, was recaptured, according to Lucas, 12 days later, 3,150 miles distant.

Our familiar small birds do not travel at anything like such a rate, but their endurance is very great, as we can realize in view of their migrations, which often reach from the northern United States to equatorial South America, while the small waders travel from one end of the hemisphere to the other. See MIGRATION.

Flying creatures occur among mammals, reptiles, and fishes. The extinct pterodactyls were evidently experts on the wing, and some of them constituted the largest flying animals of which we have any record. Of mammals the bats are the only true flyers, the flying squirrels and lemurs having merely parachute-like expansions of skin on the sides of the body which when the legs are stretched out enable them to sail obliquely downward from the tree tops to the lower branches.

In the flying-fish (q.v.) there is an enormous development of the pectoral fins which simulate wings. Their flight, however, consists only of a short sail through the air on an impetus gained as they leap from the waves with the fins rigidly extended.

Consult: E. J. Marcy, 'Vol des Oiseaux' (Paris 1890); Prof. Chas. S. Roy, article 'Flight,' in 'Newton's Dictionary of Birds' (1896); Prof. S. P. Langley, 'The Greatest Flying Creature,' Smithsonian Report 1901.

Flightless Birds. Certain birds are quite unable to fly, or fly very poorly, or use their wings only as paddles or balancers, or in extreme cases have lost not only the use of wings, but the wings themselves have disappeared. Examples of this degeneration will be found treated of in the articles upon APTERYX; DODO; GAREFOWLS; MOA; OSTRICH; PENGUIN; RATITÆ; SOLITAIRE.

Flinch, a card game said to have had its origin in Kalamazoo, Mich., and to have been invented by a man named Flinch. The game is played with a pack of 150 cards, numbered consecutively from 1 to 15, there being 10 cards of each numeral. All are of the same color; there are no hearts, diamonds, clubs or spades, and the court cards, are, of course, also missing. The cards are shuffled, and 10 cards are dealt to each player for his flinch pile, then 5 more to each to play with. Each player must place his flinch stack face up, with only the top card exposed. The other five cards are kept in hand, spread out like a fan to see the numbers, for flinch has not as yet the dignity of indexed-edged cards. The object of the game is to get rid of the flinch pile, and whoever first succeeds wins the game. To this end the flinch pile must be played from whenever possible. When this is not done, the opponent will call «flinch,» and the player will have to draw a card from the opponent's flinch pile and place it on the bottom of his own. In case two or more of the opponents call «flinch» at the same time, the negligent player must draw a card from the pack. The game may be played by any number from two to eight. After shuffling, the entire pack is usually stacked up criss-cross into hands of five, to facilitate drawing new hands.

Flinck, Govaert, Dutch painter: b. Cleves 25 Jan. 1615; d. Amsterdam 2 Feb. 1660. At Amsterdam, where he took up his permanent residence, he became a pupil of Rembrandt, whose manner and technique he so closely imitated that he comes nearer to the master than any other of his pupils, with the exception of Eeckhout. He was much sought after as a portrait painter, and has also left many religious pictures and a few genres, such as 'Die Wachstube,' which is equally Rembrandtesque in subject, conception and treatment.

Flind'ers, Matthew, English navigator: b. Donington, Lincolnshire, England, 10 March 1774; d. London 19 July 1814. He did much toward mapping out the coastline of Australia. In his first voyage of discovery he started in 1795 from Port Jackson, and skirting the southeast coast reached Van Diemen's Land. In a subsequent voyage of discovery, on which he was despatched by the British government with but poor equipment, he sailed along the south coast to Cape Leeuwin, and the bay which now bears his name. He next explored the east coast of Australia, from Port Stephens to Cape Palmentone; threaded the formidable Barrier Reefs, and coasted the Gulf of Carpentaria. Then turning back he made for Europe, by way of Sydney. He was shipwrecked on this voyage and detained by the French in Isle de France for seven years. From the effects of this imprisonment he never recovered. On his arrival home he published 'A History of Terra Australis.' The coast of South Australia was long called after him Flinders Land. His name is still attached to the southernmost county in Eyre Peninsula, and to Flinders Island, off that coast; to the Flinders Range in South Australia, rising near the head of Spencer Gulf, and running north (highest peaks, 3,100 feet); also to a town in Victoria, 61 miles southeast of Melbourne. See Life by Thynne (1896).

Flinders-Petrie, William M. See PETRIE, WILLIAM MATTHEW FLINDERS.

Flindersia (named after Captain Matthew Flinders), a genus of trees of the order *Meliaceæ,* allied to the mahogany, to which, however, it is generally inferior. The trees of this genus are tall, with a correspondingly great diameter, and furnish large quantities of valuable timber. *F. australis,* the Queensland ash, is used in Australia for staves, etc.; *F. oxleyana* is a hardwood tree yielding excellent material for cabinet-work, and also furnishing a yellow dye. The wood of *F. greavesii* is used in housebuilding, for which it is well adapted by its durability.

Flint, Austin, American physician: b. Petersham, Mass., 30 Oct. 1812; d. New York 13 March 1886. He was graduated at the medical department of Harvard College in 1833. After practising in Northampton, Mass., Boston, and Buffalo, where he established the Buffalo 'Medical Journal' in 1846, he was one of the founders, and for six years a professor, of the Buffalo Medical College. He was a professor in Louisville University 1852-6; professor of pathology in the Long Island College Hospital in 1861-8; president of the New York Academy of Medicine in 1872-5, and of the American Medical Association in 1884. He was the author of numerous text-books, clinical reports and medical papers.

Flint, Austin, American physician, son of the preceding: b. Northampton, Mass., 28 March 1836. He was graduated from the Jefferson Medical College, Philadelphia, 1857, and removing to New York in 1861 became professor of physiology in Bellevue Hospital Medical College, and surgeon-general in 1874. He has published 'Text-book of Human Physiology'; 'Physiology of Man; 'The Source of Muscular

Power'; 'Chemical Examinations of Urine in Disease'; etc.

Flint, Grover (originally **Flint Grover**), American writer: b. New York 27 June 1867. He was graduated at Harvard in 1888 and from 1892-4 served in the United States army as cavalryman. In 1896 he went to Cuba and served with a Cuban insurgent army, and returning to the United States, some months later, married a daughter of John Fiske (q.v.). He served in Cuba in the Spanish-American war and subsequently went to the Philippines as a lieutenant of volunteers. He has published 'Marching With Gomez, With Historical Introduction by John Fiske' (1898).

Flint, Timothy, American author: b. North Reading, Mass., 11 July 1780; d. Salem, Mass., 16 Aug. 1840. He was a Congregational minister during 1812-4; subsequently he devoted himself to editorial work, descriptive writing, and fiction. In these departments his most important work is included in: 'The Geography and History of the Mississippi Valley'; 'Indian Wars in the West'; and 'Francis Berrian'; 'George Mason;' and 'The Shoshone Valley.'

Flint, Weston, American librarian: b. Pike, N. Y., 4 July 1835; d. Washington, D. C., 6 April 1906. He was graduated at Union College in 1860, and at the law department of Columbia University in 1877. He was United States consul to China 1871-4; librarian of the Scientific Library, United States Patent Office, in 1877-87; and was appointed librarian and secretary of the board of trustees of the Public Library in Washington in 1898. His publications include: 'Catalogue of the Library of the United States Patent Office' (1878); 'Catalogue of Additions to the Library of the United States Patent Office, 1878-82'; and 'Statistics of Libraries in the United States, Canada, and Washington' (1893).

Flint, Mich., a city and county-seat of Genesee County, on the Flint River and on the Chicago and Grand T. and the Flint and P. M. R.R.'s; 64 miles northwest of Detroit. Flint has a court-house, the State Institution for the Deaf and Dumb, a private retreat for the insane, a high school, waterworks, gas and electric lights, public library, a national bank, and several daily, weekly, and monthly periodicals. It has a large number of saw-mills, carriage and wagon factories, flour- and woolen-mills, bicycle-works, brewery, etc., and an assessed property valuation of about $13,000,000. Pop. (1901) 13,103.

Flint, or **Flintshire,** North Wales, a maritime county having on the north the Irish Sea and on the east the river Dee and Cheshire, with the county of Denbigh on the west. Its area is 256 square miles, and it is the smallest county in Wales. The low and sandy coast becomes fertile along the estuary of the Dee. A range of hills running parallel to the Dee rises in the highest part to 825 feet. The Carboniferous rocks underlie Flintshire, and the chief minerals are coal, iron, copper, lead, zinc, and limestone. Mining is the principal industry, and there are some manufactures of cotton, pottery, chemicals, etc. The chief towns are Flint, St. Asaph, Mold, Holywell, and Hawarden. Pop. (1901) 81,490.

Flint, Wales, a market town and seaport, in Flintshire, 13 miles southwest of Liverpool. It has a handsome parish church in the Gothic style, erected in 1848. Near the town, on the shore of the estuary, stands the ancient castle of Flint, an object of some historical interest. It was completed by Edward I., and was the prison of Richard II. It has remained in ruins since 1667. Flint is on the Chester and H. R.R. Pop. (1901) 4,624.

Flint, a massive variety of quartz, somewhat resembling chalcedony, but more opaque, and commonly of a gray or smoky-brown color, darker in the interior than on the surface. It occurs abundantly in the United States and in various other parts of the world. In England and France it occurs chiefly in the chalk formations, and a microscopic examination of it often shows the remains of diatoms and other minute organisms, from whose silicious skeletons the silica of the flint was doubtless largely derived. In other cases the flint was probably formed by the replacement of lime by silica held in solution by the ground water. The coloring matter of flint is chiefly carbonaceous matter, with some iron sesquioxide. Flint was used for many ages in the manufacture of stone implements, a use for which it is well adapted by its hardness, and also from the fact that it breaks with a conchoidal fracture, leaving sharp cutting edges. Previous to the invention of matches, flints were greatly used for the production of fire, the flint being struck repeatedly against a piece of steel, from which it detached small particles that were rendered red-hot by the friction. These were caused to fall into a mass of very dry and highly inflammable matter, known as "tinder," which took fire from them as dry grass beside a railroad takes fire from the sparks of passing locomotives. Before the invention of the percussion cap, flints were also used on musket locks, for igniting the powder.

Flint Glass. See GLASS.

Flint Implements, tools, weapons, etc., made of silicious or flinty stones; a term particularly denoting implements used by man before the use of metals. See STONE AGE.

Flint Mill, (1) In pottery, a mill in which burnt flints, having been previously stamped to reduce them below a certain size, are ground to powder for mixing with clay to form slip for porcelain. The flint-mill is a strong circular pan 10 or 12 feet in diameter, having a bottom of quartz or feldspar blocks, and a runner or runners of hard silicious stone, called chert, lime in any form being inadmissible, as it forms a flux for the other material which would vitrify in the seggars or become blistered by the escape of carbonic acid. (2) In mining, a mode formerly adopted for lighting mines, in which flints studded on the surface of a wheel were made to strike against a steel, the blows producing a quick succession of sparks, which lighted the miner at his work.

Flint River, one of the largest rivers in Georgia, rising near Atlanta and flowing 300 miles to the Gulf. It drains an area of 8,000 square miles.

Flintlock, the old-fashioned lock for firearms, in which the cock held a piece of flint, and came glancing down upon the steel cap of the pan which contained the priming. See FIREARMS; MUSKET.

Floating Battery, a vessel strengthened so as to be shot-proof, or as nearly so as possible, and intended for operating in comparatively smooth water, for defending harbors or attacking fortifications. The most notable attempt to make use of floating batteries against maritime fortresses, till the time of the Crimean war, was during the siege of Gibraltar in 1782, when batteries of this description, invented by the Chevalier d'Arçon, were employed at first with considerable effect. On this occasion, however, they turned out in the end a complete failure, being destroyed by the red-hot shot directed against them from the fort. After this failure no more attention was paid to them until Napoleon III. suggested the use of floating batteries, protected by iron plates, in attacking the Russian fortresses in the Black Sea and the Baltic. The suggestion was actually carried out, and the floating batteries then constructed proved very effective in 1855, during the operations against Sveaborg and Kinburn, as well as on subsequent occasions.

Floating Bridge. See Bridge.

Floating Docks. See Docks.

Floating Fern. See *Filicales* (4), under Ferns and Fern Allies.

Floating Gardens. See Floating Islands.

Floating Houses, abodes so constructed as to be movable at will upon the surface of a river or other water. Floating houses form whole streets in Bangkok, being anchored in rows and capable of being moved from one position to another. From the depth of water, large vessels of from 200 to 300 tons burden can sail up to this picturesque town and pass alongside the houses of the inhabitants. These floating houses are made of bamboo stems, wicker-work, and palms, with a veranda in front; and they are built on large rafts. See Bangkok.

Floating Islands, islands formed either by the aggregation of driftwood in rivers and the deposition thereon of soil and vegetable matter, or by the detachment of portions of a river-bank or lake-shore. Tall trees are sometimes seen standing erect on such islands as they are carried down by the river current. Floating islands are sometimes seen 50 or 100 miles distant from the mouth of the large rivers of America, Asia and Africa. Portions of the alluvial soil from river-deltas, held together by the roots of mangroves and other trees, are sometimes detached by hurricanes or typhoons and then swept out to sea; such islands have been met with in the Philippines, in the seas of the East Indies, and in the Pacific. A floating island is mentioned by Herodotus as existing in Egypt. Others were known to Roman writers. Those on Lake Vadimona were, according to the younger Pliny, capable of supporting sheep. Loch Lomond in Scotland long possessed a floating island, which has now, however, disappeared or become attached to one of the stationary islands of the loch. In Ireland large masses of peat float about some of the bogs. In England, in Lake Derwentwater, there is an instance of an island which appears and disappears from time to time in the same spot. Perhaps the most satisfactory of the many theories which have been proposed to account for this phenomenon is that which attributes its rising from the bottom of the lake, where it ordinarily rests, to the permeation of its mass by marsh-gas during hot weather, the upward motion being assisted by the growth of buoyant water-plants on its surface. Between 1696 and 1829, similar islands were observed at irregular intervals, generally, however, after great droughts and violent storms, in Lake Rålang in the Swedish province of Småland. Oceanic floating islands sometimes perform important service in the transportation of vegetable seeds from place to place, also in the distribution of animal species, by carrying insects, land mollusca, and small mammalia, more rarely reptiles. Darwin met with islands floating on Lake Tagua-Cagua in Chile which passed from side to side of the lake and carried cattle and horses as passengers. In Northern India, and on the borders of Tibet, and Persia, floating gardens are often erected by the natives, for the purpose of raising melons, cucumbers, and other similar vegetables and plants, which require a very aqueous soil for their cultivation. These gardens, however, are of a very fragile nature, and rarely exceed a foot in depth of soil, their prime structure being composed of wicker-work, interlaced with reeds and wattles, and covered with matting, over which the earth is placed. In the Vale of Cashmere the lakes contain floating gardens devoted to the same purpose, but these are in reality portions of the marshy ground made to float artificially by cutting through the roots of the reeds and other plants about two feet below the surface. The Chinese, too, devote considerable attention to this style of horticulture, but more by way of ornamentation. Floating gardens, or *chinampas,* also existed in Mexico before the Spanish conquest. Clavigero describes them as formed of wicker-work, the stems of water-plants, and mud, the largest sometimes having on them a tree or a hut. Both flowers and vegetables were grown on them.

Floats. (1) In angling, the quill or cork from which the bait line is suspended, and whose motion indicates the bite of a fish. (2) An inflated bag or pillow to sustain a person in the water. (3) The small piece of ivory on the surface of the mercury in the basin of a barometer. (4) The hollow, metallic ball of a self-acting faucet, which floats on the water in the cistern or boiler. (5) A raft, or collection of timber fastened together for conveyance down a river. (6) In hydraulic engineering, one of the boards or paddles attached to the radial arms of a paddle wheel or water wheel. (7) In machinery, a single-cut file, or one in which the teeth are parallel and unbroken by a second row of crossing teeth. The usual horizontal obliquity of the teeth relatively to the central line of files is 55°, but single-cut files are much less inclined, and the teeth of floats are sometimes square across the face of the file. (8) In plastering, a plasterer's trowel used in spreading or floating the plaster on to a wall or other surface. The long-float is of such a length as to require two men to use it. The hand-float is that in ordinary use. The quirk-float is used in finishing moldings. An angle-float is shaped to fit the angle formed by the walls of a room. (9) In masonry, a polishing-block used in marble working; a runner. (10) In shoe making, the serrated plate used by shoemakers for rasping off the ends of the pegs inside the boot or shoe. (11) In tempering, a contrivance for affording a copious stream of water to the heated steel surface of an object of large bulk, such as an anvil or die in the process of tempering. The rapid production of steam prevents the constant contact of cold water when the object is merely dipped, as a body of steam intervenes. The dashing stream of water constantly exposes a new body of water to the hot surface, and makes the hardening more complete. (12) Theatrical: A stage name for the footlights, derived from the use of a row of oil-pans, with floating wicks, along the stage-front, previous to the invention of gas.

Float-stone, a variety of opal, or hydrated silica, occurring in concretionary masses of such a porous texture that they float on water. They are of a gray or white color, break with uneven fracture, and sometimes have a hard nucleus of a flinty appearance.

Flodden, flod'n, a village in Northumberland, England, about five miles southeast of Coldstream, near which was fought the celebrated battle in which James IV. of Scotland was defeated by the Earl of Surrey (9 Sept. 1513). See SCOTLAND.

Floe-rat. See SEAL.

Flogging, the infliction of stripes or blows with a whip, lash, or scourge, especially as a judicial punishment. In Britain it long existed as a punishment in the army and navy; but it was totally abolished in the former in 1881, and in the latter it is practically extinct. It was made a punishment for certain violent crimes, such as garrotting, in 1863; and for juvenile offenders in 1847 and 1850. In these cases, however, the number of stripes is limited by law, 50 being the maximum in some instances, 25 in others, and so on. A judge in sentencing a prisoner to flogging must specify the instrument and the number of stripes. In the case of juveniles under 14 years of age the instrument must be a birch rod, and the number of stripes must not exceed 12. The punishment of the knout in Russia and of the bastinado in the East are severe forms of this punishment. In the United States, flogging was discontinued in the navy and on merchant vessels in 1850. In the army, it was abolished 1861. As a means of prison discipline, it has been used till very recently, and its disuse is a subject of debate. For the subject of its use as a legal punishment for certain offenses, see FLAGELLATION; WHIPPING-POST.

Flood, flud, **Henry,** Irish orator and politician: b. near Kilkenny 1732; d. Farmky, county Kilkenny, Ireland, 2 Dec. 1791. He was educated at Trinity College, Dublin, and Christ Church, Oxford, entered the Irish parliament in 1759, and soon became the most prominent and eloquent member of the popular opposition. He was privy councilor for Great Britain as well as for Ireland in 1775, and vice-treasurer for Ireland 1775-81. In 1783 he had a personal dispute in the house with Grattan, when a remarkable display of the power of invective was made on both sides. He afterward became a member of the British Parliament for Winchester and Seaford. His speeches were published in 1787. See Lecky: 'Leaders of Public Opinion in Ireland' (1872).

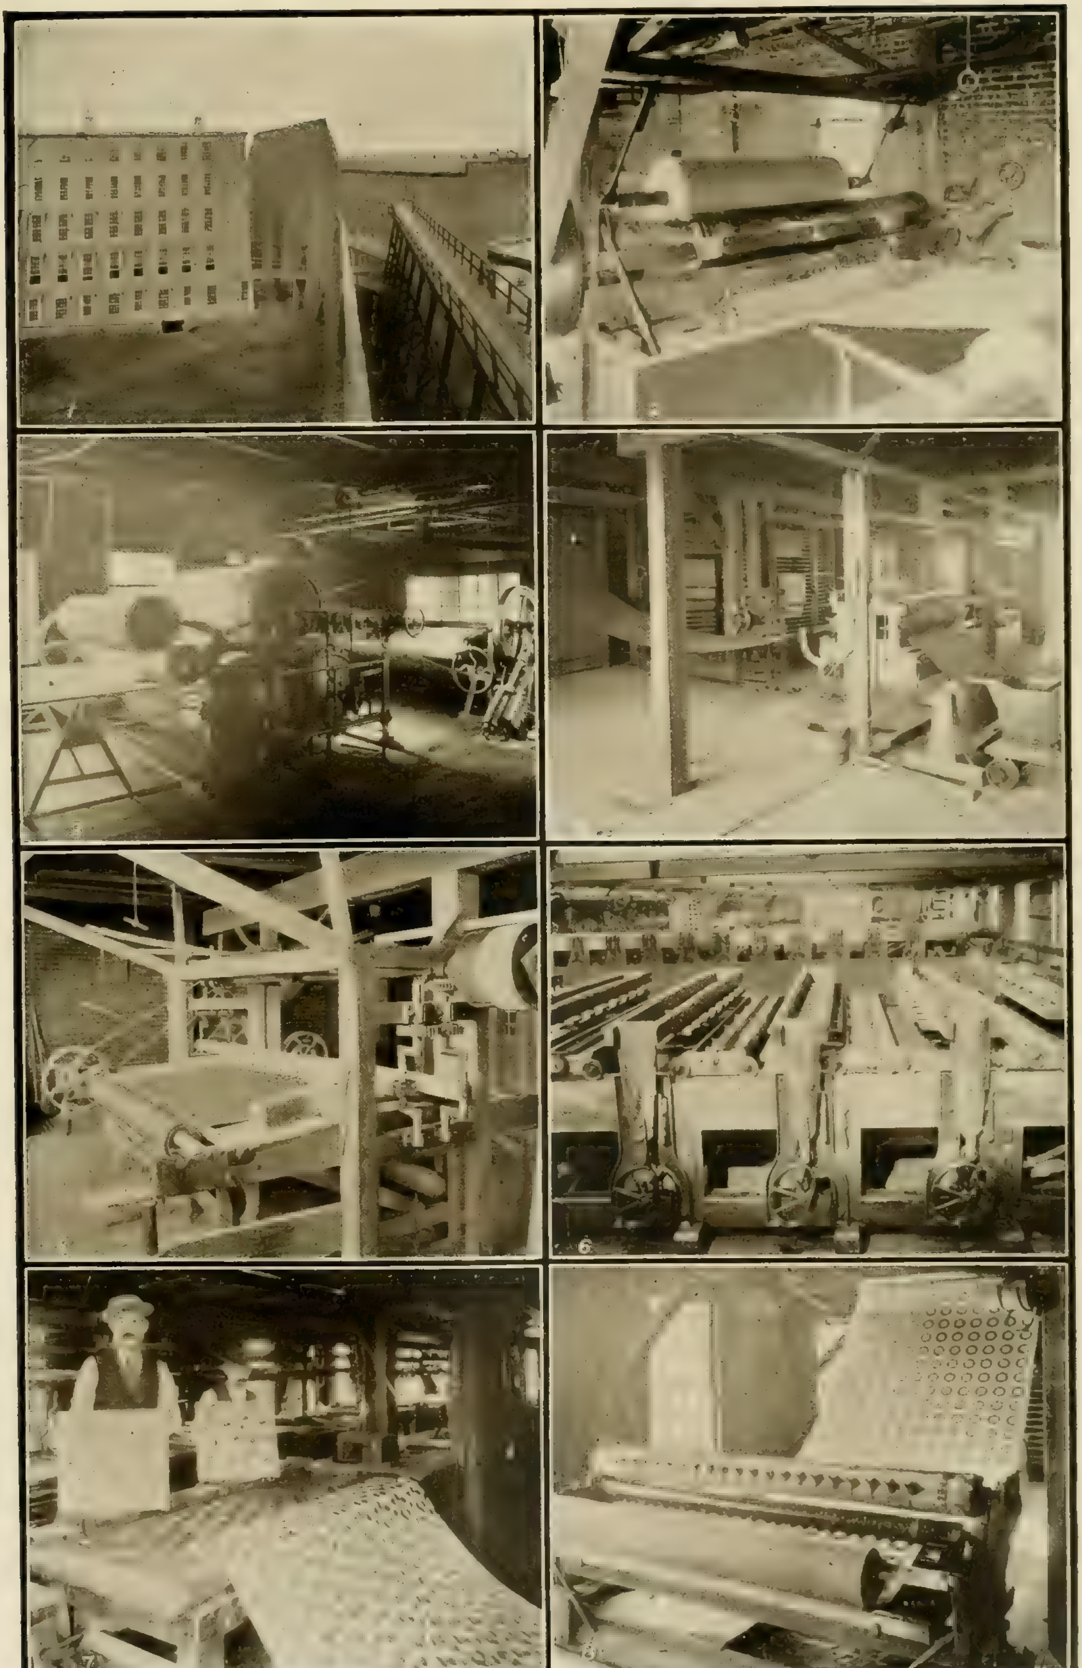
Flood, Theodore L., American Methodist clergyman: b. Williamsburg, Pa., 20 Feb. 1842. He served in the Federal army in the Civil War, entered the Methodist ministry, and after an active pastorate of 15 years became connected with the Chautauqua movement. He edited the Chautauqua Assembly 'Herald,' which began its monthly issue at Meadville, Pa., in 1877, and became 'The Chautauquan' in 1880. He retired from its editorship and ownership in 1899. He has been active in various denominational and commercial enterprises and was an unsuccessful Republican candidate for Congress in 1892.

Flood Plain, the plain formed by a river in broadening its valley. The first work done by a river is to cut a trench-like valley, this having been cut so deeply that the slope of the river-bed toward the sea so slackens the current of the river that it cannot carry its load of detritus, this detritus is partly dropped. Then the upbuilding of the river channel causes the river current to swing from side to side. In this way first one side, then the other of the valley is attacked by the river. In time of flood the plain of waste thus accumulated may be entirely covered by the swollen river. The flood plain of the Mississippi west of Tennessee is 50 miles wide. See RIVER; VALLEY.

Floods and Inundations are caused by excessive rains, giving rise to an overflow of the rivers; by the bursting of the banks of rivers, lakes, and reservoirs; by the sudden melting of ice and snow; and by irruptions of the sea, produced by high tides, wind-storms driving the sea-water inland, earthquakes, volcanic outbreaks, and the bursting of sea banks. The felling of forest trees throughout extensive tracts of mountainous country also tends to make the rivers which have their origin there swell rapidly after a heavy rainfall; good and complete drainage of land has the same tendency. (For the Noachian flood, see DELUGE.) The subjoined list embraces some of the most disastrous floods and inundations of which we have record.

684 A.D. Japan; 780 sq. m. of Isle of Shikoku covered by sea.
968. Persian Gulf; many cities destroyed and new islands formed by irruption of sea.
1014. Many English seaports destroyed by sea.
1098 or 1100. East of Kent inundated; Goodwin Sands formed.
1100 or 1108. Flanders inundated.
1161 or 1165. Sicily; irruption of sea; thousands drowned.
1170. Holland and Friesland; great flood.
1173. Holland; Zuyder Zee much enlarged.
1219. Nordland, Norway; lake burst; 36,000 people perished.
1228. Friesland; invasion of sea; 100,000 people drowned.
1277. Friesland; the Dollart formed.
1286–7. Holland on both sides of Zuyder Zee inundated in consequence of a storm.
1396. Holland; islands of Texel, Vlieland, and Wieringen separated from mainland, and Marsdiep, the channel between Texel and North Holland, formed.
1421 or 1446. Holland; 72 villages inundated, of which 20 permanently, about 100,000 persons drowned, Biebosch formed east of Dordrecht, and this town separated from mainland.
1521. Holland; 100,000 lives lost by an inundation.
1570. Holland; storm drove in the sea, destroying numerous villages and 20,000 people in Friesland.
1617. Catalonia, Spain; 15,000 perished in floods.
1629. Mexico (city) inundated.
1642. China, at Kaifong; 300,000 drowned.
1646. Holland and Friesland inundated; loss of life, 110,000.
1726. Floods and inundations all over Europe.
1745. Peru; Callao destroyed by irruption of sea caused by earthquakes.
1767. England; irruption of sea on east coast.

MANUFACTURE OF OIL-CLOTH.



1. Fire Wall and Railroads.
2. Sizing Machine.
3. Calender End of the Sizing Machine.
4. Painting Machine and Drying Racks.
5. Rubbing Machine.
6. Printing Machine Running Nine Colors.
7. Hand Printing a Mosaic Pattern.
8. Varnishing the Printed Oil-Cloth.

1782. Formosa; west side of island submerged, and Taiwan destroyed.
1787–8. India, in Northwestern Provinces and Punjab; 15,000 lives lost by floods.
1791. Cuba; floods from excessive rain; 3,000 drowned.
1811. Hungary; 24 villages swept away by overflow of Danube.
1813. Austria, Hungary, Poland, and Prussian Silesia; floods caused by rains; 4,000 perished in Poland, 6,000 in Silesia.
1824. St. Petersburg and Cronstadt; 10,000 lives lost from overflow of Neva.
1825. Denmark; sea broke through from North Sea to Limfjord, making northern Jutland an island; one third of Friesland submerged by rising of sea and rivers.
1840. France; overflow of Saône and Rhone swept away many villages and inundated Lyons, Avignon, Nimes, Marseilles, etc.
1851. Northern China; Yellow River burst its banks, and made a new outlet into Gulf of Pechili.
1852. Floods throughout Europe from Belgium to Switzerland.
1856. South of France; floods did damage to extent of $28,000,000.
1868. Peru; Arica and Iquique nearly destroyed by earthquake waves.
1874. United States; Mill River valley (Mass.) inundated by bursting of a dam; 144 drowned. Also floods in western Pennsylvania; 220 drowned.
1875. Disastrous floods throughout central Europe, in United States, Burma, India, and West Indies.
1876. China floods in northern provinces; in Bengal 200,000 persons perished from inundation of a tidal wave.
1883. Java and Sumatra; parts submerged by volcanic wave. (See Krakatoa.)
1887. China; the Hoang-ho in Ho-nan; millions of lives lost.
1889. Johnstown, Pa.; reservoir burst; 2,209 lives lost.
1891. Consuegra, Spain; 1,200 lives lost.
1893. Queensland; great destruction of property.
1896. Japan; 27,000 lives lost.
1900. Galveston, Tex.; 6,000 lives lost and 3,000 buildings destroyed.
1903. Kansas City, Mo., and Mississippi River towns; millions of dollars in property destroyed; few lives lost.
1903. Heppner, Oregon; cloudburst; 300 lives lost.

Floor. (1) In building, the surface on which a person walks in a room or house. It may be of masonry, bricks, tiles, concrete, earth, boards. The term usually refers to boards laid close together and nailed to timbers which are termed joists. (2) In geology and archæology, the part of a cavern corresponding in situation to the floor of a house. Here frequently there is now cave earth, covered, and therefore hermetically sealed for the purpose of the investigator, by stalagmite, which has been formed by droppings from the stalactites hanging from the roof. (3) As a nautical term, the bottom part of the hold on each side of the keelson; the flat portion of a vessel's hold. (4) In hydraulic engineering, the inner piece of the two which together form the bucket of an overshot water wheel. (5) In mining, the bottom of a coal seam; the underlay on which the coal, lead, or iron ore rests. (6) To take the floor: To rise to address a public meeting; also to stand up to dance (Irish).

Floor-cloth, or Oil-cloth. The basis of floor-cloth is a strong, open canvas, woven of flax, with a slight admixture of hemp. Owing to its great width, 6 to 8 yards, it has to be woven in special looms. It is made in lengths of from 100 to 113 yards. A length of 60 to 100 feet is stretched in a frame, brushed with glue-size, and rubbed with pumice-stones. It then receives two or three foundation coats of paint on each side. This is a thick paint, commonly made of linseed oil and ochre, and is laid on with a trowel. Each coat on the front is smoothed with pumice-stone. When this operation is completed the cloth is transferred to the printing-room, where the pattern is printed by blocks, as in calico-printing. There is a block for each color.

Floquet, Charles Thomas, sharl tō-mä flō-kā, French statesman: b. St. Jean de Luz 5 Oct. 1828; d. Paris 18 Jan. 1896. He began life as a lawyer in Paris, where he defended the Republican journalists. On the fall of the empire he was appointed one of the deputy mayors of Paris, but was forced to resign on account of his complaisance toward the Red Republicans. Later he was elected to the Paris municipal council and in 1876 became one of the deputies for Paris. He sat in the Chamber till 1882, when he was appointed Prefect of the Seine; re-entered the Chamber in 1882 and was elected its president in 1885, but resigned in April 1888, to become prime minister. In 1889 he was again elected president of the Chamber. He aspired to the presidency of the republic, for which office he was the Radical candidate in 1887; but his career was cut short by the Panama Canal scandal, and he lost his seat in the elections of 1893.

Floquet, Pierre Amable, pē-ār ä-mäbl, French historian: b. Rouen, France, 9 July 1797; d. Formentin 6 Aug. 1881. He made Normandy's annals and personages the objects of his painstaking study in 'Norman Anecdotes'; 'History of the Parliament of Normandy' (1840-3); and 'Studies in the Life of Bossuet' (1855), the last two of which were crowned by the Academy.

Flo'ra, the Roman goddess of flowers and spring, whose worship was established at Rome in the earliest times. She is represented as a beautiful female, with a wreath of flowers on her head or in her left hand; in her right hand she generally holds a cornucopia. Her temple at Rome was situated near the Circus Maximus, and her festival, the Floralia, was celebrated from 28 April to 1 May. The later Romans identified Flora with the Greek goddess Chloris. In botany Flora signifies the plants of a region collectively, as Fauna signifies the animals. In astronomy an asteroid discovered by Hind, 18 Oct. 1847.

Flore'al, flō-rā-äl («month of flowers»), the eighth month in the calendar of the first French republic (1794). It began 20 April and ended 20 May. See CALENDAR.

Flor'ence, William Jermyn (stage name of BERNARD CONLIN), American comedian: b. Albany, N. Y., 1831; d. Philadelphia, Pa., 1891. He began his career as an actor at Brougham's Lyceum, N. Y., in 1850, and soon became a great favorite with the public, especially in such characters as 'Bob Brierly'; 'Sir Lucius O'Trigger,' which latter he played to Joseph Jefferson's 'Bob Acres' with great success in a series of joint performances during the last two years of his life. He was the author of several Yankee and Irish plays.

Florence of Worcester, English chronicler: d. 1118. He was a monk of Worcester, wrote 'Chronicon and Chronicis,' a compilation from Marianus, an Irish monastic chronicler, which is of the highest authority in early British and Irish history.

Florence, Ala., a city and county-seat of Lauderdale County, on the Tennessee river, and on the Memphis and C., the Louisville, and the

Nashville R.R.'s. Here are the Florence Synodical Female College, the State Normal College, Mars Hill Academy, Florence Institute, Paxton high school, a Congregational school, several churches, and a number of weekly newspapers. The city has manufactories of iron, cotton, wagons, ice, flour, stoves, etc., and an assessed property valuation of over $2,000,000. Pop. (1900) 6,478.

Florence (in Italian, *Firenze*), a province of Italy; area, about 2,262 English square miles. The surface is beautifully diversified by mountains, valleys, and plains. The climate is generally mild and healthy, and the soil very fertile, producing wheat, maize, beans, and all kinds of leguminous crops. The vine, olive, orange, citron, and fig thrive well in the low grounds; while the mountainous districts afford excellent pasture, admirably adapted for the rearing of sheep. The minerals include mines of copper, lead, and mercury; and quarries of marble, alabaster, and fine building stone. Pop. (1901) 939,054.

Florence (Italian, *Firenze*), a famous walled city of central Italy; on both sides of the Arno, 187 miles northwest of Rome. It stands in a richly wooded, well-cultivated, and beautiful valley, encircled by the Apennines. Its shape is nearly a square, the sides of which almost correspond with the cardinal points; the Arno intersects it from southeast to northwest, three of the quarters into which it is divided being situated on the right, and the fourth on the left bank of the river. The communication between the opposite sides of the river is maintained by means of seven bridges. Florence contains a great number of magnificent edifices and squares, generally adorned with statues, columns, or fountains; there are no fewer than 170 churches, 89 convents, 2 royal, and many other palaces, 12 hospitals, and 8 theatres great and small. Each angle of a street presents an architectural view fit to be drawn for a scene in a theatre. Many of the houses are palaces, fitted up with great magnificence, and some of them contain valuable galleries of pictures. The streets are mostly wide and straight; and they are admirably paved with angular blocks of sandstone.

The Piazza Reale is the largest square; it has a fine marble fountain, and an equestrian statue in bronze of Duke Cosmo I., by John of Bologna. The Piazza del Mercato Vecchio, in the centre of the city, has a marble column from which Florence radiates for one mile on each side. The Arno is decidedly superior to the Tiber at Rome. The bridge Santa Trinita, built of marble in 1559 by Ammanate, is designed in a style of elegance and simplicity unrivaled by the most successful efforts of modern artists. The bridges, and quays by which the river is bordered, afford fine views of the river, Florence being in this respect much superior to the "Eternal City." The duomo, or cathedral, a vast edifice, coated with marble, about 500 feet in length, and 384 feet in height to the top of the cross, stands in a spacious square. The church of Santa Croce, called the Pantheon of Florence, is interesting from its containing the remains and tombs of four of the greatest men of modern Italy, or indeed of modern times — Michelangelo, Galileo, Machiavelli, and Alfieri. Among the palaces are the Palazzo Vecchio, or Old Palace, inhabited by the Medici when citizens of Florence, which was begun in 1298, and finished in 1550. It is in a massive, severe, and gloomy style, with a tower 268 feet high, and is now occupied by the principal public offices. Adjoining it is the Piazza del Palazzo Vecchio, a square containing a fine collection of statues, and a noble arcade, the Loggia di Lanzi, under the porticoes of which are magnificent groups of sculpture. The Palazzo Pitti, erected in 1440, the ordinary residence of the king of Italy, is a vast and heavy structure; it is furnished in the most costly manner, and is enriched with a great number of the choicest works of art and vertú and an excellent library. Attached to this palace are the Boboli Gardens, laid out by Cosmo I. in 1550, in the classical style. Connected with these gardens is the botanical garden, a museum of natural history, the Fontana anatomical collection in wax, etc. Another fine palace, the Riccardi (built in 1440), has a noble gallery with a ceiling painted by Luca Giordano, and a library of 40,000 volumes, open to the public. But the crowning glory of Florence is its Grand Gallery, occupying the upper floor of the Ufizi, a building erected after a design of Vasari, by Cosmo I., consisting of two parallel corridors or galleries, each 448 feet in length, and 72 feet apart, united at one end by a third corridor. This contains some masterpieces of statuary, as the world-renowned 'Venus de Medici,' 'The Knife-Grinder,' the 'Fawn,' 'Niobe and Her Children,' etc. The collection of pictures comprises superb examples of all the best schools, and is said to surpass even that of the Vatican. A splendid apartment, known as the Tribuna, contains the rarest treasures of the collection, and is in itself a wonder of art, with its cupola inlaid with mother-of-pearl, and its rich marble pavement. Besides the Riccardi and Laurentian libraries, the Magliabecchi Library, containing a rare, extensive, and valuable collection of books, is also open to the public.

The literary and educational institutions of Florence are both numerous and important. At the head of these is the famous Academia della Crusca. The charitable institutions are numerous, extensive and well conducted. The common people of Florence are well clothed and have a comfortable appearance; and there are, as compared with most other Italian towns, few beggars, priests, and monks. The citizens are friendly, cheerful, and hospitable. The encouragement given under the government, to artistic and scientific studies, has conferred advantages on Florence unknown in most other parts of Italy. All sorts of foreign publications are met with here; and the facilities it affords for gratifying a taste for the fine arts, the beauty and security of the city and environs, and its salubrity and cheapness, make it, on the whole, a more desirable residence even than Rome. Manufactures silks, straw hats, articles of vertú, as intaglios, etc., jewelry, porcelain, perfumery, etc. Florence has produced more celebrated men than any other place in Italy, or, perhaps, of Europe; among others may be specified Dante, Petrarch, Boccaccio, Villani, Cosmo and Lorenzo de Medici; Galileo, Michelangelo, Leonardo da Vinci, Benvenuto Cellini, Alberti, Lapo Brunelleschi, Giotto, Andrea del Sarto, Machiavelli; Popes Leo X. and XI., and Clement VII., VIII., and XI.

Florence owes its origin to a colony of Roman soldiers sent thither by Octavianus after the victory of Perugia, to whom he allotted part of the territory of the colony of Fiesole, established about 40 years before by Sylla. Little more is known of it under the empire, and hardly any remains exist of that period, except some relics of an amphitheatre and a few inscriptions. Christianity was established here in the third century, and early in the fourth a Bishop of Florence attended a council at Rome. In the beginning of the 12th century the city had risen into importance through the industry and enterprise of its inhabitants, who had now commercial establishments in the Levant, France, and other parts, and had become money-changers, money-lenders, jewelers, and goldsmiths. In the latter end of the 14th century the wealthy family of the Albizzi became chief rulers in Florence. These again were overthrown in 1434 by Cosmo de Medici, a popular citizen and princely merchant, who assumed the first place in the state. On the fall of the republic in the 16th century a member of a lateral branch of the Medici, the line of Cosmo having become extinct, was placed by Charles V. as Duke of Florence. The ducal dynasty of Medici continued to rule till the year 1737, when, becoming extinct, they were succeeded by Francis of Lorraine, afterward emperor of Germany. From this period the history of Florence merges into that of Tuscany, until its amalgamation with the kingdom of Italy. From 1865 till 1871 it held the dignity of capital of the kingdom, the seat of government being transferred to it from Turin. It then received a considerable increase of population, and consequently a number of broad new streets have been constructed on the site of the old fortifications, and of late years its precincts have been extended in every direction. Pop. (1901) 205,589.

Florence, S. C., a city and county-seat of Florence County, on the Atlantic C. L. R.R. It has a bank and several newspapers. Pop. (1900) 4,647.

Florentine Experiment, in physics, an experiment made in 1661 by some academicians at Florence to test whether or not water was compressible. They enclosed it in a globe of thin gold, afterward hermetically sealed. In compressing the globe the water, instead of yielding, forced its way through the pores of the gold, and stood in drops on its outer surface. See PHYSICS.

Florentine Fresco, a kind of painting, first practised at Florence during the flourishing period of Italian art, for decorating walls. Like common fresco, the lime is used wet, but in this mode it can be moistened, and kept damp and fit for painting upon. See FLORENCE; ITALY.

Florentine Lake, in painting, a pigment prepared from cochineal. It is now obsolete, the greater durability in oil-painting of the lake prepared from madder having entirely superseded those prepared from cochineal.

Florentine Mosaic, the term applied to the art of inlaying tables and other plane surfaces with *pietra dura* and *pietra commerse,* carried on principally at Florence. See ART; FLORENCE; ITALY.

Florentine School, an Italian school of painting during the 14th and 15th centuries remarkable for greatness; for attitudes seemingly in motion; for a certain dark severity; for an expression of strength by which grace is perhaps excluded; and for a character of design approaching to the gigantic. The Tuscan artists, satisfied with commanding the admiration, seem to have considered the art of pleasing as beneath their notice. This school has an indisputable title to the veneration of all the lovers of the arts, as the first in Italy which cultivated them. See ART.

Flores, Juan José, hoo-än' hō-sā' flō'rāz, Venezuelan soldier and statesman: b. Porto Cabello, Venezuela, 1801; d. Guayaquil, Ecuador, 1 Oct. 1864. He distinguished himself as Bolivar's lieutenant in the war that secured the independence of South America. In 1823 he was governor of Pasto, and head of the army in Ecuador. His victory at Tarqui (1828) ended the war with Peru and he was made president of the republic of Ecuador (1831–5). He filled the same office in 1839 and from 1843 to 1845, when he resigned in consequence of a revolution stirred up by the liberals. He was defeated by Mosqueza in the war with Columbia at the battle of Cuaspuda, in 1863.

Flores, Venancio, vā-nän'thî-ō, South American soldier and statesman: d. Montevideo, Uruguay, 19 Feb. 1868. In 1853 he took part in an insurrection against Giro, the president of Uruguay and was elected president of the republic in January 1854. The two parties in the government were the Colored (Liberals), and the Whites (Conservatives), and the former being the stronger had elected Flores. A division in this party made it possible for a former president, Oribe, to land with troops, and Flores laid down his office, and in 1858 took refuge in Buenos Ayres. He returned later and with the help of Brazil stormed the city of La Florida in 1864 and in 1865 made a triumphant entry into Montevideo, and assumed the title of provisional governor of the republic. On 4 May 1865, he concluded a treaty of alliance with Brazil and the Argentine republic in the war against Paraguay. He won over the party of the Whites by his clemency, regained the presidency in 1866, but was assassinated on his way to the city hall, or capital of Montevideo.

Flores, flō'res. (1) *Endé* or *Mandfirei Floris,* a large island (Dutch) of the Indian Archipelago, forms one of the chain of islands which extend east from Java; length, about 200 miles; breadth, about 50 miles. It has a mountainous surface, with several volcanic peaks, one of which, Lobetobie, is 7,200 feet high. Little is known of the interior. Sandal-wood, once abundant, has become scarce. Endé, near the middle of the south coast, is said to be the principal port, and to have safe anchorage for any number of ships. The passage between the east end of the island and those of Solor and Adenara is called Flores Strait; and the part of the Pacific north of the Flores chain and south of Celebes is called the Flores Sea. (2) The most western island of the Azores, about 30 miles long by 9 miles broad, with a hilly surface, containing an extinct crater now converted into a lake. The chief products are wheat, pulse, and poultry, and great numbers of small cattle are reared. (3) An island of the North Pacific, off the west coast of British America, opposite to Vancouver's Island; lat. 49° 20′ north; lon. 125°

45′ west; length, northwest to southeast, 15 miles; breadth, from 2 miles to 6 miles. (4) A small island off the coast of Uruguay. (5) A river in Brazil in the province of Piauhy.

Florez, Henrique, en-rē'keth flō'reth, Spanish historian: b. Valladolid, Spain, 14 Feb. 1701; d. Madrid 20 Aug. 1773. He was an Augustinian ordinary who taught theology and history by presenting dogmas and annals from the standpoint of their human interest. 'Sacred Spain' (1747–73), and 'Memorials of Catholic Queens' are his most important works.

Florian, Jean Pierre Claris de, zhōṅ pē-ār clä-rē dē flō-ryäṅ, French poet: b. near Anduza, Gard, France, 6 March 1755; d. Sceaux, France, 13 Sept. 1794. He made his début with some pleasing farces (1779), and added greatly to his fame with the two pastoral stories, 'Galatea' (1783), and 'Estelle' (1787); sentimental romances in the dominant taste of that time. He also wrote: 'Medleys of Poetry and Literature'; and 'Florian's Youth,' in which he recounts the story of his boyhood. In 1788 he became a member of the French Academy. While there, engaged in finishing his poem, 'Ephraim,' he was arrested by the orders of the Committee of Public Safety, but the fall of Robespierre saved him from the guillotine.

Floriculture in America.— Growing flowers as a business was unknown in America previous to about 1825; and, indeed as late as 50 years ago it was impossible to buy cut flowers in some of our leading cities. Owing to the increase of population of the eastern cities, and consequent increase of wealth and luxury, a demand for flowers began to be felt in the second quarter of the last century; and thus began the development of commercial floriculture in this country. This branch of horticulture first became prominent in the vicinity of Philadelphia and Boston. In the early days more wealth was centered in these cities, and the people there paid more attention to luxuries in home surroundings. New York was less prominent in the development of this industry. From 1830 to 1840 floriculture made considerable progress, owing to improved methods in the construction and management of greenhouses, as well as to the increased demand for flowers. The application of hot-water heat to greenhouses gave an impetus to the work, making it possible to grow better plants than had been done when heated air conducted through brick flues was the only means of keeping out the frost. Since the Civil War the development of the industry has been rapid and varied, as to extent and methods, and as to the kinds of flowers cultivated. Up to about 1885 the cultivation of plants was the leading feature of floricultural work; but since that time the rapid increase of wealth and luxury in the large cities has developed a tremendous demand for cut flowers, thus making this branch of the business the all-important one for the florist. This increased demand for cut flowers has led to specialization in floriculture and has produced the best work of the florist. Older flowers, such as the once popular camellia, have been dropped, and the rose, carnation, violet and chrysanthemum have been substituted. In this way floriculture, as we find it to-day, has been gradually evolved. There are two distinct departments of the word, viz., the growing of plants, and the cultivation of cut flowers. The plants grown mostly are various kinds of palms, ferns, rubber plants and dracænas; also ornamental a. . bedding stock for out-door purposes. There has been specialization in both of these main branches of floriculture. For instance, certain growers devote all their energies to palms; others concentrate on ferns; others raise bedding-plants exclusively. In flower-growing there has been even greater specialization; and it would now be difficult to find an important establishment where more than one of the leading flowers is grown. While one florist will grow roses exclusively, another will devote all his time and ingenuity to the improvement of the carnation, a third will grow nothing but violets, and a fourth will concentrate on chrysanthemums. These four flowers are the most important cut flowers, their commercial importance being in the order named. The most recent statistics on floriculture in the United States are to be found in the United States Census of 1900. At that time there were 8,799 floricultural establishments, representing an investment (land, equipment, etc.), of $52,462,419, and selling flowers and plants to the amount of $18,759,464 annually. About two-thirds of this amount was realized from cut flowers, the rose bringing in $6,000,000, the carnation $4,000,000, the violet $750,000, the chrysanthemum only $500,000, owing to the shortness of the season. The annual expenditure for labor was $4,155,179, or 22.6 per cent. of the total receipts. Since the figures given above are something less than the wholesale price, and the profit of the retailer is about 100 per cent., it is clear that the public spends annually some $30,000,000 on flowers.

There are few adequate treatments of floriculture. As among the best may be mentioned: Henderson, 'Practical Floriculture'; Hunt, 'How to Grow Cut Flowers'; Taft, 'Greenhouse Management.' Consult also Bailey's 'Garden-Craft' series, and his 'Cyclopedia of American Horticulture.' See BOTANY; BREEDING PLANT; HORTICULTURE; FLOWER; FLOWER AND INSECTS; GARDEN; INFLORESCENCE; GREENHOUSE; CROSS-FERTILIZATION; FERTILIZATION, ETC.

Florida (Sp. flowery, a name given to the country by Ponce de Leon because he discovered it on Easter Day, Sp. *Pascua florida* or *de flores*, flowery Easter; or, according to some authorities, on account of the exuberance of flowers which he saw), the southeasternmost State of the Union, sometimes called "the Everglade State," and also "the Peninsular State." It is situated between lat. 24° 30′ and 31° N. and lon. 79° 48′ and 87° 38′ W. Alabama and Georgia bound it on the north, the Atlantic Ocean on the east. On the South, Florida Strait, which connects the Gulf of Mexico with the Atlantic, separates the peninsula from Cuba, and the Bahamas. West of the peninsula and south of the western extension of the State is the Gulf

of Mexico. The extreme western boundary is the Perdido River in Alabama.

Florida is mainly a peninsula of irregularly rectangular form. The northern part is continental, and extends about 400 miles from east to west. From north to south the peninsula extension is about 375 miles in length, and nearly 100 miles in width, the total length of the State north and south being about 450 miles. From Biscayne Bay, near its southeastern extremity, stretches a series of islets or keys, the only one of importance being Key West, situated at the lower end of the chain.

The physical features of the State are decidedly dissimilar to those of the other Southern States. The geological upheaval resulting in its formation left neither table-land nor mountain from which to view ocean and gulf, the most elevated portion of the State barely reaching the dignity of a hill-country. Its area is 58,680 square miles, 4,440 being lakes, lagoons, and rivers. Its coast-line, excluding islands, is 1,145 miles, 470 miles of it being in the Atlantic Ocean. Capital, Tallahassee.

Surface, Soil and Drainage.— The northwestern part, continuing the Alabama uplands, is a hilly rolling country sinking to a flat strip of coast. The east is part of the Atlantic coastal plain. The peninsula is a surface of sand and marsh, lying in the north on a basis of Upper Eocene or Vicksburg limestone; in the south on one of coral whose southern extremity is the bounding wall of the Gulf Stream, silted up at the end into the "keys." These have spread by deposits and vegetable growth into habitable islands, and in the course of ages will be joined to the peninsula, which itself is yet but land in the making. Almost everywhere the water lies close below the surface, which is dotted with springs, some of which are charged with carbonates and sulphuretted hydrogen; many fresh and of immense size, and of crystal clearness. One of the most famous is near St. Augustine, two miles out at sea, and boils so violently that the waves break against it as against a sunken reef. Another large one is in St. George's Sound, opposite Lanark. The wonderful Silver Spring, at the head of navigation on the Ocklawaha River, near Ocala, Marion County, has an estimated outflow of 300,000,000 gallons daily. The Blue, in the same county, the Wekiva in Orange County, and the Wakulla near Tallahassee, are also famous.

As the soil is a mere surface deposit with no volcanic upheaval, the State has no real hills; but the centre has a watershed in the shape of a ridge from 100 to 300 feet high, with a summit level 200 miles north of the strait, from which low sand-terraces decline each way to the sea, with countless lakes and swamps at their bases. Many of the lakes are aggregates of the great springs before mentioned. The largest is Okeechobee in the south, 1,200 square miles in area and 25 feet above the sea-level, its waters sinking into the Everglades; a bordering rim of sand about 25 miles wide divides it from the Atlantic. Others are Monroe, Georgia, Kissimmee, Crescent, Dexter, Apopka, Harris, Orange, and Eustis. Most of them are shallow and usually connected by fresh-water streams. On the higher levels the terraces are covered with a magnificent growth of large pine-trees; on the lower levels are prairies and marshes timbered with cypress-trees, and in which are "hummocks," which are dry elevations, covered with a great variety of hardwood, and cabbage-palms. The basins of the draining streams are mostly marshy jungles of cane-brake and vines and semi-tropical trees. In the southernmost portion are the remarkable Everglades, forming a district 160 by 60 miles in extent, and containing 3,600 square miles, both land and water; and overflowed marsh hidden by tall grass, and thickly dotted with dry "hummocks" ranging in size from those just large enough to stand on, up to those covering a square mile or more, and covered by a jungle of vines and shrubs, pine, and palmetto. The eastern part is a maze of these islands and small shallow bayous. The islands were once really such in the ocean, the water around them having silted up and been overgrown with vegetation. The Everglades are separated from the Gulf by extensive cypress swamps; the forests extend down the west coast, narrowing out around the cape, and stretch up along the Atlantic coast. The latter, except in the extreme north, is almost harborless, a line of narrow sand-spits with interior lagoons, the type of the whole southern coast; but the gulf side, otherwise formed in the same fashion, is pierced with many deep bays and harbors — Pensacola, Santa Rosa, St. Andrew's, St. George's, Appalachee, Tampa, Hillsboro, Charlotte Harbor, Oyster, Ponce de Leon, Cedar Keys, etc.

The great river of Florida is the St. John's, rising in Cypress Swamps, just north of the Everglades, and flowing north parallel with the ocean, threaded on a series of lakes; 150 miles from its mouth becoming a mile wide, and in its lower course six or seven, a miniature Amazon in size and character and draining a similar country. Pleasure-steamers navigate it 250 miles, and the tributary swamp-rivers several hundred more. Its total course is 350. The Kissimmee, flowing into Lake Okeechobee from Kissimmee Lake, is also a favorite of tourists and sportsmen. The leading streams of the west are the Suwanee; the great Appalachicola from Georgia, 90 miles long under that name, with a course of nearly 600 through the Chattahoochee; the Choctawhatchee (180 miles), and Escambia (250 with the Conecuh) from Alabama, the latter navigable to the Conecuh.

Climate.— The climate of Florida is not subject to prolonged and severe winters with great ranges in temperatures. The annual precipitation is from 58 to 60 inches, ranging from 6 to 8 inches in the fall and winter — the dry season — to 18 to 20 inches during the summer. The normal sunshine is about 60 per cent. The normal mean temperature for January ranges from 60° to 70° F., that for July being 80° and above. The hottest months are June, July, and August, the heat being tempered by frequent showers. Already famed as the Riviera of America, offering hope to the invalid and pleasure and comfort to the robust, Florida occupies a unique place among the States of the Union. The large immigration of a rich and cultured class has had a great influence on the social, political, and business development of the State.

Flora and Fauna.— These are naturally affiliated to those of the West Indies and South America. The forests are estimated at 25,000,000 acres, two thirds the area of the State; largely consisting of live-oak, hickory, long-leaved pine, pitch-pine, and cypress. Prof. A. H. Curtis, a distinguished botanist, says that Florida has a greater variety of trees than any other State in the Union. Florida has many trees peculiar to itself, or almost so, in the United States — the wild orange, cocoanut, and Indian almond, mahogany, satinwood, and manchineel, cachibou and kino-gum, etc. The tropical fruit acclimated there is noted below. The alligator, green turtle, and sponge, indicate the tropic nature of the State.

Fish and Fisheries.— Florida's enormous coast-line in the mid-continental seas gives its fisheries the greatest extent and value of any State south of Virginia; they employ seven or eight thousand men. Foremost is that of the red snapper, utilizing some 200 vessels besides hundreds of boats, the headquarters being Pensacola; the catch is over $2,000,000 a year, mostly packed in ice and sent North. Shad, mullet, and green turtle are also caught in large quantities. The sponge fishery is peculiar to Florida, and centres in Key West; it has produced as much as $250,000 a year. Alligators are caught for their skins.

Agriculture and Forest Products.— The rich phosphatic soil mingled with decaying vegetation, the large rainfall, and warm climate render Florida enormously fertile, and dictate its representative crops. It of course raises corn and other cereals for its own use — in 1902 it produced 5,180,000 bushels of corn from 600,000 acres of land — and at last report had over 500,000 neat and 80,000 dairy cattle; but its chief export crops are semi-tropical. Sugarcane, Sea Island cotton, and rice; 160,000 bushels a year of the last named; sweet potatoes, over 2,000,000 bushels a year; Irish potatoes, 200,000 bushels; peanuts, over 1,000,000 bushels; cassava, nearly 10,000,000 pounds; tobacco, 1,600,000 pounds in 1902; with some 7,000,000 watermelons and 3,500,000 muskmelons a year, besides general market-gardening products for the North, are the typical field crops of the State. Several thousand acres are devoted to watermelons for the seed alone, for which there is an extensive northern market. The orchard crops are rich in tropical products — lemons (2,357 boxes in the census year), limes (22,714 boxes), grape-fruit (2,306 boxes), guavas (1,645,000 fruit), Japanese plums (75,110 fruit), olives, figs (66,680 pounds), cocoanuts (136,600 nuts), etc.; but the two leading crops are oranges and pineapples. The former has been subject to immense vicissitudes. Early in the nineties it was the one speculation of central Florida, and the product rose to 5,000,000 boxes in one year; then the terrible cold wave of 1894–5 froze millions of young trees to the roots, often splitting them in two. The older trees, where well handled, generally survived, but another cold wave in 1899 — giving native Floridans the unprecedented sight of several inches of snow — destroyed a large part of those also; the two disasters killed three fourths of all the orange trees in the State. The crop sank to 125,000 boxes or so, and most of the growers abandoned the business, thinking a permanent change of climate had set in; but it is now known that these frosts occurred now and then in earlier times as well, and growers are recovering courage, though the industry is shifting toward the southwest coast. The crop for 1902 was about 750,000 boxes, over treble that for the census year. The next greatest orchard crop — though peaches and pears are considerably grown — is the pineapple, raised mainly in the southeastern counties. Florida in the census year produced nearly 3,000,000 of the fruit, against 440 from California and none from any other State.

In 1902 the Florida East Coast & Drainage Sugar Company was formed to drain the Everglades, which will reclaim some millions of acres of valuable agricultural land.

The forest products are usually ranked under manufactures. The lumber and timber product of Florida in 1899–1900, with the tar, turpentine, and ship stores, amounted to $17,572,999, or nearly as much as all the rest of the State's manufactures together. The turpentine and rosin — 236,778 barrels of the former, 772,537 of the latter — were valued at $6,469,605, and the industry employed 15,073 hands, or toward half the industrial workers of the State. The industry has grown from almost nothing within the decade, there being in 1890 only 484 hands and $191,859 product.

Minerals.— Florida has no metals, and its mineral industries are of rock and earths. The chief is the mining of phosphate rock for fertilizers (q.v.), in which it rivals any other district of the world. It is in various forms — hard and soft rock, land and river pebble, and vertebrate remains. The hard rock — much the most valuable, containing 80 per cent phosphate of lime — is found in a belt skirting the Gulf from Tallahassee nearly to Tampa. It was discovered in 1888, and since then the product has risen to some 750,000 tons a year of all kinds — 500,000 being hard rock, nearly all exported to Europe, principally Germany. The river pebble is only worked on the Peace and Alafia rivers, by dredges and pumps. Most of the fuller's earth used in the United States is also from Florida. At Ellenton, on the Manatee River, 60,000 tons has been produced in a year, and at Quincy 30,000 tons. Some $40,000 a year of kaolin also goes out.

Manufactures.— The greatest industry of Florida, aside from the forest products, is the tobacco and cigar manufacture, of which the heart is Tampa and Key West; it was developed by the immigration of Cuban cigarmakers, and still uses mainly Havana leaf. Some 300,000,000 cigars a year are turned out, and the total value of tobacco products manufactured in the census year was $10,891,286; the industry employed 6,461 wage-earners. The fertilizer industry from phosphate rock amounts to over $500,000 a year, against less than $100,000 in 1890, and nothing two years before. Wooden boxes and barrels, cedar for lead-pencils, sugarcane syrup, cotton-seed oil, and meal are also to some extent exported, though the consumption is largely at home. Jacksonville has two establishments for canning pineapples, guavas, etc.

Commerce and Transportation.— Florida's position makes it the natural outlet for exports to the West Indies; but till late years unimproved harbors and inferior railroad equipment have checked its commerce. Within the past 15 years, however, Congress has expended over $6,000,000 on its river and harbor improvements (appropriating nearly $3,000,000 more in 1902); and its railroad lines have more than trebled in mileage, and increased in even greater ratio in quality of service. The mainland harbors on its immense peninsular coast-line, with its noble

island port Key West, do an export trade of toward $20,000,000 a year, with some $2,000,000 of imports. About 3,000 vessels a year, of over 2,500,000 gross tons, clear from Florida ports. The chief exports are timber and lumber (over $7,500,000 a year), naval stores, fruits, corn, cotton, tobacco and cigars, phosphate rock and fertilizer, fish, and horses, mules, and cattle to Cuba. The largest exporting places are Pensacola, Tampa, Jacksonville, and Key West. There are important steamer lines running from Jacksonville to Charleston, New York and Boston; from Tampa to Havana and Porto Rico (great sums having been recently expended on its terminal facilities); from Key West to Havana, Galveston, New Orleans, and New York; and from Miami to Nassau and Cuba; also coasting lines from Fernandina, Apalachicola, Carrabelle, and Punta Gorda. There is much tourist and business navigation on its fine rivers and bays. The railroad mileage is now some 3,500, of which 2,800 is main track; there are several through express trains to and from the North daily, and three great trunk lines traverse the peninsula — the Atlantic Coast Line, Seaboard Air Line, and Florida East Coast.

Banks.— On 1 Jan. 1902 there were 25 incorporated banks in the State, with assets of $6,149,852.82; and capital, surplus, and undivided profits of $1,169,645.70. Five of these were savings banks or had savings departments, with assets of $2,632,928.31.

Finance.— The assessed valuation of the State is slightly over $100,000,000; and there is no floating debt, but a surplus of $228,074.19 in the treasury on 1 Jan. 1903. The bonded debt is $350,000 in 7's of 1871, and $925,000 in 6's of 1873. The State tax is five mills. The county taxes produce over $1,250,000 a year, the school districts over $70,000.

Education.— At the end of 1902 there were about 2,400 public schools, and 2,799 teachers, 1,782 of them female. The average monthly salary was $44.49 for white males and $35.44 for white females. Total paid for salaries, $569,733.33; total expenditure on schools, $775,000, or about $1.35 per capita; about half the average for the Union, and one of the lowest averages among the States. The average attendance for the year was 55 days for white children, 41 for colored. The illiterates above 10 number over one fifth of the population. This is misleading, however, unless classed by color: the illiterate whites numbered 19,184 out of 297,812, or 6.4 per cent, while the illiterate colored numbered 65,101 out of 230,730, or over 35 per cent. The educational status is gradually improving. There are some 30 high schools in the State. The Constitution provides for two normal schools, a white and a colored; the former is at De Funiak Springs, the latter at Tallahassee. There are also three private normal schools. For colored secondary education there are three institutions at Jacksonville and one at Live Oak. For whites there are, besides the State Agricultural College at Lake City, seminaries for East Florida at Gainesville, West Florida at Tallahassee, South Florida at Bartow. There are also several private and denominational colleges, including the John B. Stetson University at Deland, affiliated with the University of Chicago, and Rollins College at Winter Park.

Charitable and Penal Institutions.— There is a State hospital for the insane at Tallahassee accommodating about 1,000 patients, and treating some 300 new ones a year; a school for the blind and for deaf-mutes at St. Augustine; and a State reform school. The State penitentiary at the end of 1902 had 1,033 inmates; 449 received during the year, of whom 413 were colored. The State farms out its convicts for mining phosphate, etc.

Religious Denominations.— The strongest in the State are the African Methodist Episcopal, the Methodist Episcopal South, the Regular Baptist South, the Regular Baptist Colored, Roman Catholic, Methodist Episcopal, Protestant Episcopal, Presbyterian, Disciples, and Congregational.

State Government.—The Constitution is of November 1886, and made sweeping changes from the former one in the direction of democracy. The State and county officers had formerly been mostly appointed by the governor, and the Supreme Court justices were appointed for life; under the present Constitution all are elected, except circuit judges, and the judges' terms are six years. The governor is elected for four years, and cannot be re-elected for an immediately succeeding term. His salary is $3,500. His veto may be overridden by a two thirds vote of the members present in both Houses. In case of vacancy, the succession devolves on the president of the Senate and the speaker of the House successively. The legislature consists of 32 senators and 68 representatives, and meets biennially, with sessions limited to 60 days except at their own expense. There is a railroad commission to enforce reasonable rates of freight and passenger carriage. The divorce law requires two years' residence. Counties have local option at the request of one fourth of the registered voters. There are 1,258 militia. The State has two representatives in Congress. It is overwhelmingly Democratic in politics; in the legislature of 1903 there are 67 Democratic representatives and one Republican.

Population.— 1830, 34,730; 1840, 54,477; 1850, 87,445; 1860, 140,424; 1870, 187,748; 1880, 269,493; 1890, 391,422; 1900, 528,542. The foreign-born numbered 23,832, mostly West Indians. The colored population was 230,730, or a little over two fifths. The present population, based on estimates of the census officials, is about 575,000.

The State has 45 counties, which, with their capitals, are as follows:

Alachua, Gainesville.
Baker, MacClenny.
Bradford, Starke.
Brevard, Titusville.
Calhoun, Blountstown.
Citrus, Inverness.
Clay, Greencove Springs.
Columbia, Lake City.
Dade, Miami.
De Soto, Arcadia.
Duval, Jacksonville.
Escambia, Pensacola.
Franklin, Apalachicola.
Gadsden, Quincy.
Hamilton, Jasper.
Hernando, Brooksville.
Hillsboro, Tampa.
Holmes, Westville.
Jackson, Marianna.
Jefferson, Monticello.
Lafayette, Mayo.
Lake, Tavares.
Lee, Myers.
Leon, Tallahassee.
Levy, Bronson.
Liberty, Bristol.
Madison, Madison.
Manatee, Braidentown.
Marion, Ocala.
Monroe, Key West.
Nassau, Fernandina.
Orange, Orlando.
Osceola, Kissimmee.
Pasco, Dade City.
Polk, Bartow.
Putnam, Palatka.
St. John, St. Augustine.
Santa Rosa, Milton.
Sumter, Sumterville.
Suwanee, Live Oak.
Taylor, Perry
Volusia, Deland.
Wakulla, Crawfordville.
Walton, DeFuniak Springs.
Washington, Vernon.

The chief cities are Jacksonville, on the St. John's, with a population of 28,429, in 1900, increased to about 40,000 in 1903; Pensacola, in the extreme west, 17,747; Key West, 17,114; Tampa, on the west coast, 15,839. No other place has as much as 5,000 people; and only two over 4,000 — St. Augustine, on the east coast, 4,272, and Lake City, between Jacksonville and Tallahassee, 4,013. Between 3,000 and 4,000 are Gainesville, Ocala, Palatka, Fernandina, and Apalachicola. Tallahassee, the capital, has 2,981.

History.— The earliest attempted colonization of the North American mainland was in Florida, and the first white settlement was St. Augustine. Juan Ponce de Leon discovered the coast a little north of St. Augustine 27 March 1512; was made governor, and authorized to colonize the "Island of Florida," as it was then supposed to be, in 1513; and sought there for the "Fountain of Youth." Thenceforward it was the highway of Spanish explorers. Vasquez de Ayllon raided it for slaves 1520–6, Pánfilo de Narvaez began his fatal expedition westward in 1528 from Pensacola Bay; Hernando de Soto his in 1539 from Tampa Bay; Tristan de Luna in 1559 explored northward from Pensacola Bay. Coligny designing to found a Huguenot colony and refuge in the New World, René de Laudonnière in 1564 built Fort Caroline on the St. John's; in 1565 Pedro Menendez de Avilèz captured the fort, massacred the French there and in two detachments outside, "not as Frenchmen but as heretics," and built St. Augustine; in 1567 Dominique de Gourgues in turn exterminated the Spaniards at the settlement that had replaced Fort Caroline, "not as Spaniards but as assassins." St. Augustine was overlooked; but in 1586 Sir Francis Drake destroyed it. All through the 17th and early 18th centuries the Spaniards in Florida harassed, or set on the Indians to harass, the English colonies, from St. Augustine as headquarters, especially after Georgia was settled; and St. Augustine was repeatedly attacked by colonial expeditions. The Spaniards did but little toward settling the country, however. In 1763 East and West Florida — the latter west of the Apalachicola, and including parts of modern Alabama and Mississippi — were ceded to Great Britain, and in the next 20 years more than 25,000 whites had settled there. In 1783 it was retroceded to Spain, and most of the English settlers withdrew. In 1795 West Florida was sold to France. After the Louisiana Purchase of 1803 the United States claimed up to the Perdido as part of "Louisiana"; the claim was not then pressed, for fear of war; but in 1810, the Spanish monarchy being overthrown and the king a prisoner, the United States took possession of all but Mobile, which was occupied in 1813 during the War of 1812. Meantime and afterward, the Southern States found East Florida an intolerable thorn in their flesh. The so-called Spanish "government" there was mere anarchy, partly from there being no stable home government to control it; Indian bands raided Georgia and escaped over the border, British and Spanish traders intrigued with them, and it was an Alsatia for fugitive slaves which drove the slaveholders wild. Congress authorized Madison to take "temporary possession" in 1811, but nothing was done; in 1818 Jackson invaded it to punish Spanish assistance to the Seminole raids and withholding fugitive slaves, captured St. Mark's and Pensacola, and hanged Arbuthnot and Ambrister, two British adventurers making their account by furnishing supplies and possibly other help to the Indians. The district being both profitless and untenable to Spain, she ceded it to the United States by treaty of 22 Feb. 1819, in exchange for government assumption of $5,000,000 claims of American citizens against Spain. The latter only ratified it in 1821 (see ANNEXATION). In March 1822 it was admitted as a Territory. The two sections, East and West Florida, both from geographical and political reasons, had no sympathy with each other, and repeatedly petitioned Congress for separation, without avail. Especially West Florida, as late as 1869, voted for annexation to Alabama, which offered the State $1,000,000 for it; but no further steps were taken. On 11 Jan. 1839 a convention framed a constitution for the State of Florida; but it was not admitted to the Union till 3 March 1845, paired with Iowa, as a slave State with a free State. The Constitution, forbidding emancipation of slaves by the legislature, roused a violent debate in Congress over admission. From 1835 to 1842 raged the bloody Seminole war (q.v.), ending in the deportation of the tribe to Indian Territory in 1843. On 10 Jan. 1861 an ordinance of secession was passed, 62 to 7; and on 4 Feb. the Florida delegates took their seats in the Confederate Congress. The government posts nearly all fell into Confederate hands; but Fort Pickens, off Pensacola, was retained, and formed a nucleus for recapture. After 1863, however, the Union forces were employed in other quarters; and by the battle of Olustee, 20 Feb. 1864, the State was lost to the Union till the close of the War restored it. On 13 July 1865 a provisional government was formed; on 25 October a State convention met, and on the 28th annulled the ordinance of secession. A new constitution was adopted without slavery, and a legislature organized in 1866; but on 2 March 1867 it was brought under the Reconstruction Act, and became a part of the Third Military District. A constitution of 25 Feb. 1868 chose officers to hold till January 1873, and by act of 25 June 1868 Florida reorganized as a State. Reconstruction conditions here were as anarchic and deplorable as elsewhere (see ELECTORAL COMMISSION; RECONSTRUCTION); but in the last 20 years the enormous investments of Northern capital in industries and railroads, the national expenditures on harbors, etc., have made it a strong and thriving State. Consult: Norton, 'Handbook of Florida' (1892); Fairbanks, 'History of Florida' (1871); Barbour, 'Florida' (1884).

CHAS. H. SMITH,
Secretary Board of Trade, Jacksonville.

Florida Agricultural College, an important educational institution at Lake City, Florida, established in 1884. It is under the direct control of a State board appointed by the governor. There are 200 students of both sexes.

Florida Blanca, José Moñino, hō-sā' mōn-yē'nō flō-rē'thä blän'kä, COUNT OF, Spanish statesman: b. Hellin, Murcia, 21 Oct. 1728; d. Seville 20 Nov. 1808. He was Spanish ambassador at Rome during the pontificate of Clement XIV., and particularly distinguished himself by his activity in the abolition of the order of the Jesuits, and in the election of Pius VI. In 1777 he became minister of foreign affairs, and at once acquired almost unlimited authority in Spain. He introduced post-coaches, and caused the post-roads to be made practicable; directed his attention to the most important subjects of general police, particularly in the capital; embellished Madrid, and was on every occasion the active friend of the arts and sciences. His attack upon Algiers in 1777, and the siege of Gibraltar in 1782–3, were unsuccessful; but the result of his co-operation with the English colonies of North America in securing their independence was more favorable to Spain. After the accession of Charles IV., his enemies succeeded, in 1792, in effecting his disgrace. He was imprisoned in the citadel of Pampeluna, but was soon restored to liberty and banished to his estates. He appeared once more upon the political stage in 1808, when he was president of the extraordinary Cortes.

Florida Cape. See CAPE FLORIDA.

Florida, Gulf of. See FLORIDA STRAITS.

Florida Jay. See JAY.

Florida Keys, or **Reefs,** in Florida, a chain of small islands, keys or reefs, and sandbanks, extending southwest from Cape Florida, about 220 miles. They are very considerable in number, but only a few are of any importance. Among these may be mentioned Cayo Largo, Indian Key, Long Island, Old and New Matacombs, Cayo de Boca, and Key West, on which the city of Key West is built.

Florida Straits, or **New Bahama Channel.** The gulf waters separating Florida from Cuba and the Bahamas, and traversed by the Gulf Stream. The total length is 300 miles, with a width of from 50 to 150 miles.

Florida, Treaty of. In American history, a treaty signed between Spain and the United States, 22 Feb. 1819, by which Spain conceded the Floridas to the United States. Until the final ratification of the treaty Congress had passed a law empowering the President to appoint a governor, and Gen. Andrew Jackson assumed command of the Florida region. Gen. Jackson issued a proclamation at Pensacola requiring obedience to United States authority. See FLORIDA; UNITED STATES — ARBITRATION IN THE.

Florin, the name of a coin first struck in Florence in the 13th century. The silver florins of Holland are worth about 40 cents. The British and Austrian florins are each worth 50 cents. The English florin was first coined in 1849. See NUMISMATICS.

Florio, Caryl. See ROBJOHN, W. J.

Florio, John, English lexicographer and translator: b. London of Italian parents about 1553; d. 1625. He taught French and Italian in Oxford University, and was appointed by James I. teacher of languages to the queen and Prince Henry. His chief works are his great Italian and English dictionary, 'A World of Words' (1598, improved edition 1611), and his translation of 'Montaigne' (1603).

Floris, flō'ris, **Frans** (originally **de Vriendt**), Flemish painter: b. Antwerp 1517; d. there 1 Oct. 1570. He was called by his contemporaries the Raphael of Flanders. He went to Italy, where his taste, particularly in design, was improved by the study of the masterpieces of Michelangelo; but he never equaled the grace and purity of form which distinguished the Florentine and Roman masters. His style was grand; but his coloring and his figures are reproached with dryness and stiffness. Most of his works, and in particular his triumphal arches, made on the occasion of the entry of Charles V. and Philip II. into Antwerp, and his 'Twelve Labors of Hercules,' have often been engraved by skilful artists. His paintings are to be met with in Flanders, Holland, Spain, Paris, Vienna, and Dresden.

Flor'izel, in Shakespeare's 'Winter's Tale'; the Prince of Bohemia, hero of the drama, and the lover of Perdita.

Flo'rus, Roman historian, of the 2d century A.D., probably a native of Spain or Gaul. He is variously styled in the manuscripts; in some L. Annæus Florus, in others L. Julius Florus, in others L. Annæus Seneca, and in one simply L. Annæus. He wrote an abridgment (epitome) of Roman history in four books, from the foundation of the city to the first time of closing the Temple of Janus, in the reign of Augustus. His style is florid, and not sufficiently simple for history. The best edition is that of Duker (Leyden 1744); later ones are by Titze (1819) and Seebode (1821).

Floss Silk, the portions of raveled silk broken off in reeling the silk from the cocoons, carded and spun into a soft coarse yarn, and used for common fabrics. See SILK.

Flotow, Friedrich (frēd'riH flō'tō) **von,** German musical composer, b. Teutendorf, Mecklenburg-Schwerin, 27 April 1812; d. Wiesbaden 24 Jan. 1803. His earlier operas (which include one called 'Rob Roy') did not find favor among the Parisian opera-house directors, so he had to content himself with performances in the private theatres of the aristocracy. This brought him gradually into notice, however, and his 'Naufrage de la Méduse' was publicly produced in 1839. 'Alessandro Stradello' was first performed at Hamburg in 1844, and his most successful opera, 'Martha,' was originally given at Vienna in 1847. His subsequent works, such as 'Indra' (1852), 'Rübezahl' (1854), 'Albin' (1856), 'L'Ombre' (1869), achieved but small success.

Flotsam, Jetsam, and **Ligan,** in law, flotsam, or floatsam, is derelict or shipwrecked goods floating on the sea; jetsam, goods thrown overboard which sink and remain under water; and ligan, goods sunk with a wreck or attached to a buoy, as a mark of ownership. When found such goods may be returned to the owner if he appear; if not, in England, they are the property of the crown. See DERELICT; SALVAGE.

Flounder, any of several of the more common and useful flat fishes (q.v.) of northern waters. The commonest American species are the "summer" and "winter" flounders. The latter (*Pseudopleuronectes americanus*) is dark rusty brown, more or less spotted, about 15 inches long when large, and weighs one to two pounds. It is caught in the colder months from Chesapeake Bay to Labrador, and is excellent eating. The "summer" flounder (*Paralichthys dentatus*) becomes twice as large, is light olive brown, studded, when adult, with numerous small white spots, and is excellent eating. The "four-spotted" flounder (*P. oblongus*), and the

Gulf species (*P. albiguttus*), are closely related. On the Pacific coast several good species are known; and the British coast has a valuable species in *Pleuronectes flesus,* closely resembling the plaice (q.v.).

Flour and Meal Insects. Various forms of small whitish caterpillars and darker-colored "worms" are commonly found in flour and meal and manufactured cereal products of different kinds. The most prominent of these is the Mediterranean flour moth (*Ephestia kuehniella*), which has been termed a veritable scourge in flouring-mills. It was practically unknown as a pest until 1877, and in North America is still limited to portions of California, Minnesota, New York, and Pennsylvania, where flour-milling is an important industry. The moth has a wing-expanse of a little less than an inch, and is of a pale lead-gray color. The caterpillars are whitish, with long but inconspicuous hairs, and make the trouble while searching for a proper place for transforming to the pupa stage. Wherever it crawls it drags after it a large quantity of silk, with the result that flour becomes felted together and lumpy and the mill machinery gets clogged, requiring frequent and expensive stoppages. The entire life cycle of this insect may be accomplished in 38 days, hence in well-heated mills or other buildings inhabited by the insects from four to six generations may be produced. When a mill is found infested the entire building must usually be fumigated. Sometimes a whole district becomes overrun, and in this case great care must be observed that the insect does not spread from one mill to another. Various remedies are used for eradicating the pest, including the free use of bisulphid of carbon and hydrocyanic-acid gas, the use of "steam-sweepers" and "elevator brushes."

The Indian-meal moth (*Plodia interpunctella*) somewhat resembles the preceding, but is smaller; the outer halves of the fore-wings are dark greasy brown with metallic reflections, and the larva usually has a reddish or greenish tinge. It has the same habit of webbing up flour, but is not so great a pest as the Mediterranean flour-moth, possibly because it has a larger range of food material, feeding on nearly all forms of dried vegetable matter, among which are dried fruits and jellies, which have earned it the title of "pantry moth." It is to be found in nearly every store and household, and particularly where dried vegetable foods are neglected for any length of time. The meal snout-moth (*Pyralis farinalis*) is rarer than the preceding, and seldom does injury to flour or meal, although it spoils clover hay.

Two species of beetles (*Tenebrio molitor* and *obscurus*) and their larvæ are popularly known as "meal-worms," both in this country and abroad. The former is a shining brown beetle over half an inch long, and produces a yellow meal-worm; the latter is dull black, and produces a dark brown meal-worm. They are most apt to be troublesome in dark locations, in feed-stores and in stables; but are useful when raised under control, since they are salable as food for mocking-birds, nightingales, and other cage birds.

Flour beetles or "weevils" are little flattened reddish beetles of the same family (*Tenebrionidæ*) as the meal-worms and are great pests in mills and storehouses. The chief source of annoyance from these insects is due to their imparting a highly offensive and persistent odor to the substances which they infest, which include various drugs, snuff, capsicum, ginger, dried peas and beans, baking powder, nuts, and cabinets of dried insects. Several species occur in America. They differ somewhat in structure and in habits, but may be controlled by the use of bisulphid of carbon.

Flourens, Marie Jean Pierre, mä-rē zhŏṅ pē-ār floo-roṅ, French physician and physiologist: b. Maureilhan, department Hérault, 15 April 1794; d. Montgeron, near Paris, 6 Dec. 1867. His first scientific writings, which were distinguished by their perspicuous style and analytical precision, appeared in 1819. In 1828 he was elected a member of the Academy of Sciences, in 1830 was appointed to the chair of comparative anatomy at the Jardin des Plantes, and in 1833 succeeded Dulong as permanent secretary to the Academy of Sciences. In 1840 he was admitted a member of the French Academy. In 1846 he was created by Louis Philippe a peer of France, but he was deprived of this dignity by the revolution of 1848. Flourens combined with profound scientific knowledge great literary talent. His works are very numerous, but the following may be mentioned particularly: 'Recherches expérimentales sur les Propriétés et les Fonctions du Système nerveux' (1824); 'Expériences sur le Système nerveux' (1825); 'Developpement des Os' (1842); 'Anatomie de la Peau' (1843); 'Mémoires d'Anatomie et de Physiologie comparées (1844); 'Buffon' (1844); 'De l'Instinct et de l'Intelligence des Animaux' (1841); 'De la Longévité' (1854); De la Vie et de l'Intelligence' (1858); 'Œuvres de Buffon' (1853–5); 'Des Manuscrits de Buffon' (1859); 'Éloges historiques' (1857). Flourens was the first to demonstrate experimentally that the substance of the animal body undergoes a constant process of renewal.

Flour Milling, American. Flour milling is of two kinds; one the primitive, small industry that supplies a natural local demand; the other a commercial enterprise, which goes into the open markets for its raw material and disposes of its product in the markets of the world. One dates from the early settlement of the country, or as soon as wheat was grown in America; while the other had its beginning about the time of the Revolution, though it assumed no really great importance until after the middle of the last century. While the country has, and probably always will have, a large number of small mills situated in the rural districts, the flour-milling industry proper — considered commercially — is on a larger and more important scale than ever before. In fact, the census of 1900 gives it fourth place among the manufactures of the United States in value of products.

The small mill that supplies a purely local village or rural demand, may properly be termed an "agricultural adjunct." Therefore the history of farming in this country is the history of the grist-mill development. Yet its early growth is of some interest. In 1626, a horse-power mill was built on Manhattan Island, and a windmill in New England, near Watertown, about two years later. Windmills soon became common on the Atlantic coast. The first water-mill in New England was probably built on the Dorchester side of the Neponset, in 1634. Before the middle of the century, New England was doing an export business, sending wheat and flour to Portugal. In 1649, Virginia had four windmills, five water-mills, and numerous horse-mills, and was also an exporter of wheat and flour. By 1678, New York had a considerable number of mills, and, moreover, had a monopoly on the process of the bolting of flour. The charter was repealed, however, in 1694.

For nearly 100 years following, the development of milling was but the reflection of the growth of the country, with some extension of trade in the West Indies and South America. Still, the process of milling was crude, and the industry, with perhaps a few exceptions, had hardly gone beyond the agricultural or farm-product basis. Not until the mills began to centralize, until "milling centres" began to form, did the industry commence to shape itself on a commercial basis. This period may be said to have commenced shortly after the Revolution. Yet milling then, as compared with to-day, was as the stage coach of 1776 compared with the luxurious express train of the present century. Still, the mills of Delaware, on the Brandywine, were celebrated for their flour. This district had 130 mills within a radius of 40 miles, and Wilmington was an exporter of "superfine" flour.

The next milling centre of importance, and which later became first, was Baltimore. In 1787 the mills of that city made 325 barrels of flour daily, and it was there that the first marked improvements in the process of making flour were adopted. Up to 1785 the different stages of milling were separate and largely done by hand, as they are even to-day in the Hungarian process. But Oliver Evans introduced the elevator and conveyor, and combined the different steps into a continuous system; thus dispensing with much labor, and making a saving in the cost of production. Owing to this improvement and to the slowness of the Delaware millers to adopt it, Baltimore became the more important centre, and the Patapsco River, with its fine water power, became celebrated during the next 50 years. In 1840, the Patapsco, within 30 miles in which the fall is 800 feet, had 60 mills, which ground several hundred thousand barrels of flour a year. A considerable export trade was done with the West Indies.

Still another milling centre was formed at Richmond, Va., at the falls of the James River. The district is now not known as a milling point; the milling business has passed, leaving nothing but a memory of its one-time importance. In 1845, Richmond had the largest mills in the United States, the "Gallego" and the "Haxall." The number of mills there was 21, and their trade besides the local and nearby territory, was with South America. The "Gallego" mills, in 1864, had 31 pairs of buhrs or millstones, with an annual capacity of 190,000 barrels of flour. The "Haxall" mills had a capacity of 160,000 barrels.

From the Atlantic coast the milling centre began its westward march, following the wheat-fields. Rochester, N. Y., in the Genesee valley, was the next centre, and while it retained its importance for many years, it succumbed to newer districts farther to the west. At one time Cincinnati assumed considerable importance as a milling point, but St. Louis was destined to follow Rochester as the centre of a great milling district. While Rochester at the present writing has lost its importance, St. Louis has retained its mills, but has been outclassed by the younger city of Minneapolis. Milwaukee has also developed a slightly greater milling capacity than St. Louis. Thus the milling centre has finally fixed itself, apparently for all time, at Minneapolis. For many years, however, Rochester was recognized as the first milling city of the country, having as early as 1835, no less than 21 mills, with 95 run of stones. The flour from these mills was sold throughout the Atlantic coast States. In 1865, the flour output of Rochester was 800,000 barrels.

With the development of the great central wheat States, mills were built wherever there was increased population. In 1840, Ohio, Kentucky, Indiana, Illinois, and Michigan had a total of 1,200 mills, producing about 30 per cent of all the flour made in the country, yet very few of them belonged to the commercial class, such as those of the centres. The scattered country mills supplied the farming communities and the small towns, while the few larger mills and those of the centres supplied the large markets and the districts where wheat was not raised.

St. Louis began as a milling point in 1840, with two small mills. The city, due to its location, was then the principal point in the West. By 1860, the St. Louis mills were making 800,000 barrels of flour a year. In 1870 the output was over 1,000,000 barrels, and in 1880 over 2,000,000. St. Louis led all other centres until 1881, when Minneapolis began its rapid development. Among the other important milling centres are Toledo, Buffalo, Detroit, Indianapolis, Chicago, Kansas City, and Milwaukee, already mentioned.

A small, crude mill was built at the Falls of St. Anthony, now Minneapolis, by a detachment of soldiers in 1823, but the first merchant-mill was erected in 1854. The first flour was shipped to the east from Minneapolis in 1859. In 1865, the city had six mills, with a total daily capacity of 800 barrels. It was not until 1878 that the total annual output reached 1,000,000 barrels, and the direct export shipments were about 100,000 barrels.

In tracing the movement of the milling centre, it may be of interest to investigate the causes that brought a large number of milling interests together. The importance of the first milling district, the Brandywine, in Delaware, was evidently principally due to convenient wheat supplies. The Patapsco district owed its importance to fine water power, local wheat supplies, and water transportation, while Richmond would probably never have gained any prominence but for its water power, though its transportation facilities, down the James, enabled it to build up an export trade. The fine water power of the Genesee River, at Rochester, was a natural inducement for the miller to build there, while the rich agricultural valley gave an abundant supply of raw material. Then, too, the opening of the Erie Canal gave Rochester unexcelled transportation facilities to other markets. Until other conditions entered into the situation to affect it, Rochester was particularly favored. St. Louis had no water power, but it had river transportation both for wheat and flour, and it was for years the principal distributing point for a vast territory. Milwaukee was an early wheat market and was the lake outlet for the Northwest before Chicago became a shipping point of importance. It was thus early that mills began to be built at Milwaukee, and its milling importance may be ascribed to its favored position on the lake.

The greatness of Minneapolis as a milling centre is partly due to the water power from the Mississippi River and partly to the position of the city, which is the gateway between the wheat fields and the markets, but it is also largely due to the quality of the wheat of Minnesota and the Dakotas, the greatest spring-wheat territory in the world. Lastly, the pre-eminence of Minneapolis as a milling centre is due to the early business men of genius, who grasped the situation and made the name "Minneapolis" known the world over. Given all the other advantages,— geographical position, water-power, and even the annual production of some 200,000,000 bushels of superb hard spring wheat,— yet without the business genius and enterprise that dominated the early Minneapolis millers, the city might never have been known as the greatest flour-milling centre in the world.

The latest figures at hand show the following flour output at milling centres in the United States for 1902:

	Barrels.
Atlanta	315,000
Buffalo	1,415,300
Chicago	1,300,000
Detroit	567,000
Duluth	1,804,400
Kansas City	1,298,300
La Crosse	435,100
Minneapolis	16,329,800
Milwaukee	1,755,000
New York	1,760,700
Nashville	1,000,000
Philadelphia	301,500
Rochester	402,400
Richmond	218,200
St. Louis	1,625,900
Toledo	1,600,000

The present time may be called a commercial era in the flour-milling industry. The period from 1870 to 1900 might fittingly be termed the mechanical era, for during that time greater changes and improvements were made in the process than in all the 200 years preceding it. During the mechanical period, there was also the export era, when the building of new mills and the increasing output of old ones, together with the increase in wheat raising of the country, caused an over-production of flour, if domestic markets alone were depended upon. In fact, the increased output was to keep pace with the growing export trade. After reviewing the natural development of the milling industry, which up to 1870 was identical with the growth of the country, these three divisions,— the mechanical, the export, and the commercial,— seem most important.

No better review of the mechanical period, up to 1895, can be given that that written by the late Charles A. Pillsbury, of Minneapolis, who did more than any other one man to make the city in which he lived, and the wheat of the Northwest, known in every great market of the world.

In 1895, Mr. Pillsbury wrote:

Down to 1870, the milling process in the United States was that invented by Oliver Evans, with some minor and gradual improvements. From 1787 the nether and upper millstones, the former stationary and the latter balanced to rotate upon it, ground the flour of America. The stones were set close together, to produce as much flour as possible at one grinding. This produced friction and heat, and often brought about chemical changes which injured the color, taste, and quality of the flour. In the early milling history of Minneapolis, when enterprising manufacturers rushed the speed of the stones to secure a large product, the flour came out dark, and so hot the hand could not be held in it.

Minneapolis spring-wheat flour then stood low in the scale, and was sometimes branded, at the request of buyers, "St. Louis flour from winter wheat." The hard spring-wheat, rich in gluten which made it tough, rendered difficult the separation of flour from bran, and thereby yielded a dark-hued flour which brought a low price in the market. The soft and starchy winter-wheat, on the other hand, yielded readily to the old low-grinding process; the bran was more easily separated, and the flour was lighter in color and less damaged by hard-grinding. The color and quality of spring-wheat flour were somewhat improved in the best mills by a reduction in pressure and speed and by scientific stone dressing; but the main difficulty remained. The difficulty in grinding spring-wheat by the old process was with the middlings, or that part of the kernel between the bran covering and the starchy central body. The middlings, although known to be rich in the gluten which gives wheat-flour its chief value with the baker and pastry-cook, were associated with the bran; and the richer the wheat in gluten, as in case of hard spring-wheat, the more difficult was the process of separation, because the gluten was the cause of the toughness.

The first experiments were made with a view to the purifying of middlings. In 1868, E. N. La Croix, a French millwright, came to Faribault, Minn., and experimented in making a middlings purifier, like one he had seen in France. In 1870 he removed to Minneapolis and continued his experiments. At length a machine was made, and a sample shipment of flour was sent to New York. Word came back by wire that the new flour was selling at 50 cents a barrel higher than other brands. The La Croix machine was crude and in some respects unsatisfactory, and George T. Smith produced a superior machine, different in many points, but retaining the same principle, and obtained a patent.

As a result of the new middlings purification process the mills using it added 50 cents a barrel to their profits in the first year, $1 the second year, and from $2 to $4 per barrel the third and fourth years. Thereupon George H. Christian, representing the Washburn mills, a number of head millers from other mills, and myself, representing the Pillsbury mills, went to Europe and made a thorough study of the Hungarian "high-milling" or gradual-reduction roller and middlings process. As a result some of the Minneapolis mills adopted the Hungarian process bodily, middlings purifier and all, and in a few years were compelled to throw away some of the complex machinery with which they were loaded. The Pillsbury mills, however, adopted only what seemed to be the best features of the Hungarian process, such as the rolls, made modifications all along the line, and retained the American middlings purifier invented by Mr. Smith. We found that the Hungarian system needed simplification to increase its efficiency, to save labor, and especially to avoid dangerous accumulation of mill-dust.

The new and improved high-milling system of Minneapolis and Minnesota thus established made the hard spring-wheat of the Northwest the best flour material on the globe, immediately added 10 to 15 cents per bushel to its market value, and gave Minneapolis flour the first place among the cooks and bakers of the world. By the new process chilled iron and porcelain rolls gradually came into use in place of the old millstones. The grain, in place of being ground in a single pair of millstones, was run through six or seven sets of rolls, being sifted and graded after each breaking by the rolls. The old process aimed to get as much flour as possible at one grinding; the new seeks to get as little flour as possible at the first two or three breakings. The old millstones were set so close together that the weight of the upper stone rested almost wholly upon the grain. The first rolls in the new process are set so far apart that the kernel is simply split for the liberation of the germ and crease. The old process sought to avoid middlings as far as possible, because they entailed loss of flour. The new process seeks to produce as much middlings as possible, because out of the middlings comes the high-grade patent flour. In the handlings of the middlings the new process exhibits the highest art. The gluten, which gives flour its strength or rising power, is saved and made available to the baker, and made a prominent source of profit both to the farmer who raises the wheat, the miller who grinds the flour, the baker who makes the bread, and finally to the consumer, in whom it is transformed into brain and muscle.

With the introduction of the new milling process came the big mills which have made Minneapolis famous, and the development of the spring-wheat industry which has made the Northwest known around the globe. In 1884 there were 23 mills equipped with the new process machinery and possessed of a daily capacity of 30,000 barrels.

The number of mills in Minneapolis has not increased since 1884, although the capacity has been largely increased. In 1884 the output was 5,317,600 barrels of flour, while in 1902 it was 16,329,800 barrels. This increase, without even the enlargement of any of the mill buildings, was due to improved and condensed machines. There are seven milling companies in Minneapolis, having 22 mills with a maximum daily capacity of 75,000 barrels of flour. The capacity of the individual mills is from 600 barrels daily to 15,000 barrels. The Pillsbury «A» mill, having the latter capacity, is the largest mill in the world. Four of the seven companies are small ones, having but one mill each. The mills of the three large companies have a maximum daily capacity of approximately 31,000, 27,500, and 18,000 barrels respectively. The greatest actual weekly flour production was 443,800 barrels, for the week ending 11 Oct. 1902.

Since the discovery of patent flour and the introduction of the rolls, particularly during the last 15 years, the energy and inventive genius of the mill furnishers have been directed toward economy of manufacture, to get the best out of the wheat at the least possible expense. As late as 1900, improvements were made that aided in economy of manufacture, but at this time the limit seems to have been reached in the percentage of high-grade flour that can be produced from the wheat. However, in view of what has been done, one dare not say that still further improvement cannot be made. In this connection a word should be said for patent flour. Much has been written denouncing it as unwholesome and inferior to whole wheat flours; and it has been said that it is over-refined; that the best part of the wheat is eliminated to produce a white flour. All this is without foundation. Chemical analysis and extensive digestive experiments by the United States Agricultural Department prove that white flour bread is not only more easily and completely digested than whole wheat or graham flour bread, but that it contains a greater percentage of the properties that go to nourish the human system. Patent flour is made from the middlings, or that part of the wheat lying between the bran and the starchy central portion of the berry, and it is rich in a high quality of gluten. There is probably no other manufactured article in the world that is sold as cheaply, compared with the cost of the raw material, as is patent flour.

Like the development of milling in this country, the export flour business was not placed upon a high commercial basis until the Minneapolis millers, in the early eighties, began a systematic campaign. From that time until 1900, the export trade increased steadily. Since then some adverse factors, which will be touched upon further on, have arisen. The early mills of the Atlantic coast, as already mentioned, were the first to export flour, probably to meet an actual demand because these mills were the most convenient to buy from, rather than to supply a trade that had been built up by the mills. The early export business doubtless came of itself — a natural demand. The uncertain export flour trade of the first part of the last century reached its climax in the forties, and then, when competition of European mills was felt, dropped off markedly, about the year 1850. During the next 25 years large amounts of wheat were exported annually, while the percentage of the flour production that was sent out of the country was small. The flour trade with the United Kingdom which is now an important part of the export flour business of this country, fell almost entirely away by 1865. This, perhaps, was because the American millers could not hold their own on even terms against the foreign millers, who were then becoming more aggressive and progressive than ever before. The building up of the export flour trade, beginning with about 1875, would make an interesting chapter of commercial history, for this time it was built on a foundation that no fair competition could shake.

The following table, which gives the flour output and the direct export shipments of the Minneapolis mills by years for the last 25 years, will furnish some idea of the development of the export business of the country:

Year	Output Barrels	Export Barrels
1902	16,329,800	3,362,300
1901	15,921,900	3,897,900
1900	15,082,700	4,702,500
1899	14,291,800	4,009,100
1898	14,232,600	4,052,600
1897	13,635,200	3,942,600
1896	12,874,900	3,707,300
1895	10,581,600	3,080,900
1894	9,400,500	2,370,700
1893	9,377,600	2,877,300
1892	9,750,700	3,337,200
1891	7,877,900	3,038,100
1890	6,988,800	2,107,100
1889	6,088,900	1,953,800
1888	7,056,700	2,197,500
1887	6,574,900	2,650,000
1886	6,168,000	2,288,500
1885	5,221,200	1,834,500
1884	5,317,700	1,805,900
1883	4,046,200	1,343,100
1882	3,175,900	1,201,600
1881	3,143,000	1,181,300
1880	2,051,800	799,400
1879	1,551,800	442,600
1878	940,800	107,200

A falling off of the exports will be noticed for 1901, which was true also of the general export business of the country. It was not due to the competition of other countries, but to a discrimination in freight rates, inland and ocean, whereby wheat could be exported cheaper, relatively, than flour.

The table which follows gives in condensed form a clear impression of the importance of the flour industry. Only the merchant-mills are considered. Over 5,000 small grist-mills have been omitted, as they properly belong to an agricultural review rather than to a sketch of milling.

A classification of the merchant-mills of the country for 1900 giving the States having a yearly product of $1,000,000 or over, results as shown in the following table — the second column shows the rank of the States.

The census report of 1900 says of flour milling:

"In order to form a correct idea of the magnitude of the milling industry in any given locality, it will be sufficient to compare with the number of establishments, the capital invested and the number of wage-earners employed. For in-

State or Territory	Rank	No. of mills	Raw Material—Wheat: Bushels	Raw Material—Wheat: Cost	Product—Flour: Barrels	Product—Flour: Value	Average daily product	Average value per barrel	Average bus. wheat per barrel	Average cost per bushel

stance, in the State of Minnesota, there were 512 milling establishments (including small grist-mills not included in the foregoing table) representing a capital of $24,125,781, and employed 4,086 wage-earners. The average capital invested for each establishment was $47,121, and the average number of wage-earners for each establishment was eight. Compare with this some other locality having approximately the same number of establishments, for instance, Arkansas: the total number of establishments in Arkansas was 410, representing a capital of $1,183,052, the number of wage-earners was 443, the average capital for each establishment was $2,885, and the average number of wage-earners for each establishment was one. Again, in the case of South Carolina, the total number of establishments was 556, the capital invested was $652,553, the number of wage-earners was 281, the average amount of capital invested in each establishment was $1,174, and the average number of wage-earners was only about equal to one for every two establishments in operation."

The following table shows the number of flour-mills having an annual production of 1,000 or more barrels, in States having a cereal mill product of $1,000,000 and over in which wheat flour is the chief product. (Many small mills grind rye and corn principally, and a little wheat):

One of the more recent features of the flour trade has been the considerable business by Minneapolis mills with Australia, the direct result of the crop failure there in 1902. Minneapolis mills also send flour to South Africa, and have made trial shipments to China, and there is a possibility of a trade being developed in the Far East. Pacific coast mills have introduced their flour in China and Japan, but as yet those countries are not bread-eaters. The northern transcontinental railroads, which will soon connect with an Asiatic steamship line owned by one of the roads, promises to revolutionize some of the native customs. And if China can be induced to become a bread-eater, the export flour business via the Pacific will increase very rapidly.

Commercially, the flour-milling industry has made as great progress as it has mechanically. As the skill of the mill furnisher and the operative miller has separated the best parts of the wheat into a refined and delicate product, yet retained the most wholesome and nourishing properties, as compared with the dark and coarse flour of an earlier milling age, so the work of the merchant miller of to-day differs from that of the miller of the early part of the last century.

Milling is now more a commercial and less a mechanical proposition than ever before. Mechanical perfection has nearly been reached; and it is easier to keep a machine running smoothly than to invent and perfect the machine. Perhaps the greatest commercial problem is that of competition, not only of individual millers, but of nations. It is first a competition for the raw material, and then for the flour trade. Almost every country desires to be a manufacturing nation to some extent, whether a wheat-growing country or not, therefore encouragement is given to home industries. Then, too, Europe buys large quantities of American wheat when the price is low, and later this enters into competition with American flour in foreign markets. Therefore, the flour trade is on a world-wide basis, and the large miller, more than ever before, has great commercial, rather than mechanical, problems to solve. Never, however, will he feel they have all been solved, until the United States exports the surplus of its wheat crop as the manufactured article of flour, rather than a large part of it as raw material.

Henry L. Little,
Mgr. Pillsbury-Washburn Flour Mills Co., Ltd.

Flour, Wheat, a finely ground meal used for food. Ordinary white or bread flour, of which there are a number of grades, is composed of the interior portion of the wheat kernel subjected to processes of pulverization and purification. In the preparation of white flour either a portion or all of the bran, germ, and other offal parts are removed. When the entire wheat kernel is ground into a meal, it is called graham flour. When a portion of the bran is removed but the germ and fine bran are retained, the product is called purified graham or entire wheat flour.

The history of wheat milling shows that many and gradual changes have taken place since the early times when wheat was pulverized between stones to the present time when it is reduced by steel rolls. Wheat has variously been reduced to flour by means of stone crushers, saddle stones, and stone mortars. The ancient Greeks, Romans, Chaldæans, and Egyptians used saddle stones for grinding wheat into flour, the wheat being placed in a concave stone and rubbed with a convex stone rocked backward and forward. Saddle stones are still in use among the native Africans, and are known to have been used from earliest times. They are also found among the remains of the prehistoric Swiss lake-dwellers and mention is made of them in the earliest literature. Their use appears to have been common among all primitive races and they are in use to-day by many barbarous and half-civilized nations. Near the beginning of the Christian era, querns or crude crushers in which the parts were fitted mechanically came into use. The upper stone or pestle revolved upon the lower concave stone. The quern was the forerunner of the millstone. Querns are still in use in some Asiatic and European countries. The millstone came into use about the 14th century and was the result of gradual evolution from the stones shaped by nature and operated by hand to specially hewn and dressed millstones propelled by various forms of motive power. In ancient times, flour was prepared in each household, the grinding being done by women, slaves, and menials. During the Middle Ages when the feudal system was at its height, crude flour-mills or querns formed a part of the outfit of each castle or estate. In some countries, the right to operate these mills was vested in the clergy, and in early English history frequent mention is made of contests between the people and the landlords and clergy relative to their right to operate these mills or querns.

Until the beginning of the 17th century wheat milling was simply a crude agricultural industry, the earlier mills being operated by slaves, then by oxen. Later water wheels and windmills were used as motive power. About 1820, a flour-mill was first operated by steam. At the present time, some mills are operated by electric power.

About 1870 the present roller process of flour production was introduced from Hungary into America. The process consists of the gradual reduction or pulverization of the floury portions of the wheat kernel between corrugated and smooth steel rolls and of the purification of the product by means of aspirators, sieves, and bolting cloths. During the process of milling, the granular middlings undergo gradual reduction and are passed from break to break. At each break or grinding, the fine flour is removed by bolting, the middlings are separated and passed to other rolls and the tailings are subjected to further reduction. Before passing to the rolls, the wheat is screened to remove loose dirt and weed seeds, and occasionally washed to remove adhering dirt and debris; then dried or tempered with steam, as may be necessary in order to more easily effect reduction. The first break simply flattens the kernels after splitting them in halves along the longitudinal groove. The germ is pinched off by the rolls and is readily separated. The flour passes automatically from one break or set of rolls to another. Each break is regulated so as to pulverize a little finer than the preceding one. Each stream is purified by passing through reels and by subjection to aspirators which remove the fine dust and dirt by suction. Finally the various streams are blended so as to form different grades of flour. In large mills, the cleaned wheat is usually elevated to the top of the mill, and then passed on to the rolls, and the various streams blended in such a way that the final flour product is obtained after being separated into 40 or more separate streams.

The introduction of the roller process of miling has made it possible to use varieties of wheat from which high-grade flour could not be made by the old stone process. By the roller process of reduction, the granular middlings which were formerly excluded from the flour and sold as a distinct product for animal feeding are now reduced and added to the patent grades of flour. About 75 per cent of the cleaned wheat is returned as merchantable flour, 72 per cent being straight grade or ordinary white flour. In ordinary milling, the grades are as follows: (1) first patent; (2) second patent; (3) straight, sometimes called standard patent; (4) first clear; (5) second clear; (6) red dog. First patent flour is the highest grade manufactured. Its gluten has greater power of expansion and absorbs more water than that from any other grade. First patent flour produces the whitest and largest sized loaf of bread. Second patent flour is similar to first patent, but the bread is slightly darker in color and the gluten does not possess quite so high a power of expansion. First clear grade flour is obtained after the removal of the first and second patent grades. This flour is slightly darker in color and produces a smaller sized loaf than the patent grades. Second clear or low grade is the name given to a small amount of flour obtained after the removal of the first clear. About 12 per cent of the cleaned wheat is recovered as first clear flour and about .5 per cent as second clear or low grade. When the wheat is milled so that the first and second patents and the first clear are all obtained as one flour, the product is called straight grade. This is the flour that is most extensively used for bread-making purposes. Straight flour is the sum of the first and second patents and the first clear. The lowest grade of flour manufactured is called red dog; it is dark in color and possesses but little power of expansion. It is secured largely from those portions of the wheat kernel adjacent to the germ and aleurone layers. Red dog flour is not generally used for human food, but is employed in the arts, as for foundry purposes, for the feeding of animals and occasionally in the preparation of some cereal breakfast food. It has a high per cent of protein or nitrogenous material, but is not valuable for bread-making purposes because the gliadin and glutenin (see Bread and Bread Making) are not present in the right proportions to form a balanced gluten. By blending the different standard grades of flour, various commercial grades sold under different trade names are secured. The composition and properties of different kinds of flour result from the kind of wheat used in preparation (see Wheat) and the method of milling employed. The percentage amounts of bran, shorts, and standard grades of flour obtained by the roller process vary with different kinds of wheat. Some wheats yield more flour than do others. The average yields are approximately as follows:

	Per cent of cleaned wheat recovered
1. First patent	56.0
2. Second patent	60.8
3.* Straight or standard patent	72.6
4. First clear or first bakers	11.8
5. Second clear or low-grade	0.5
6. Red dog	1.9
7. Shorts middlings	11.6
8. Bran	13.4

*Straight grade flour is composed of first and second patents and first clear grade.

By the roller process of milling, the germ is excluded because of its poor bread-making properties and its fermentable nature. The wheat offals of which shorts and bran form the main portion are by-products used for the feeding of animals. About 25 per cent of the cleaned wheat finds its way into the offals. Bran is the episperm or outer covering of the wheat kernel. As human food, it is indigestible and does not contain any appreciable amount of available nutrients. As an animal food, however, it has a high value. Shorts consist mainly of the fine bran mixed with some of the floury portions of the wheat kernel. When the wheat screenings, consisting of weed seeds and other refuse are ground and mixed with the shorts, the product is known as shorts feed. When the germ is mixed with the shorts, the term shorts middlings is used. By some processes of milling, the germ is obtained separately. From 5 to 7 per cent of the weight of the cleaned wheat is recovered as germ.

Wheat flour is composed of starch, gluten proteids, water, fat, ash, or mineral matter, and small amounts of other compounds, as sugars, cellulose, organic acids, amids, etc. The proximate composition of the different kinds of flour when milled from the same lot of hard wheat is given in the following table:

	Water, Per Cent	Protein (Nx 5.7) Per Cent	Fat Per Cent	Carbohydrates Per Cent	Ash Per Cent	Phosphoric Acid Per Cent	Acidity Per Cent	Heat of Combustion per Gram. Determined. Calories
Wheat	8.50	12.65	2.36	74.69	1.80	0.75	0.18	4.140
First patent flour	10.55	11.08	1.15	76.85	.37	.15	.08	4.032
Second patent flour	10.49	11.14	1.20	76.75	.42	.17	.08	4.006
Straight flour	10.54	11.99	1.61	75.36	.50	.20	.09	4.050
First clear grade	10.13	13.74	2.20	73.13	.80	.34	.12	4.097
Second clear grade	10.08	15.03	3.77	69.37	1.75	.56	.27	4.267
Red dog flour	9.17	18.98	7.00	61.37	3.48	....	.59	4.485
Shorts, middlings	8.73	14.87	6.37	65.47	4.56	....	.14	4.414
Bran	9.99	14.02	4.39	65.54	6.06	2.20	.23	4.198

From the table, it will be observed that there is a gradual increase in the amount of ash, proteids, and fat from the first patent flour to the red dog or lowest grade of flour. In fact, the variations in ash content of the different grades of flour are so regular that the percentage of ash can be taken as an index to the grade of flour. The highest grade flours, as first patent, contain least ash because of the more perfect exclusion of the bran and endosperm parts. There is but little difference in chemical composition between the first and second grades of patent flour, second patent, containing more fat, slightly more protein and germ, and less carbohydrates than first patent. In the straight grade or ordinary bread flour, there is only from .6 to .7 per cent less nitrogenous material as proteids than in the wheat from which it was milled. Second clear and red dog flours contain a large amount of protein, fat, and ash, and judged by their proximate composition only, would appear to have a higher nutritive value than the patents or straight grade flours. But when judged on the basis of digestibility, available nutrients and physical character of the bread, these flours are found to have a much lower value than the patents or straight grade flours. For nutritive values, see article on BREAD AND BREAD MAKING. During the process of milling, the flour particles pass through bolting cloths containing from 12,000 to 16,000 meshes per square inch, which results in even and fine granulation of the flour particles. The character of the flour particles as angular or spherical depends largely upon the character of the wheat, as hard or soft, and to a less extent upon the method of milling. The flour granules from hard wheat are angular and have a sharp feeling akin to fine sand, while soft wheat flours produce small spherical particles lacking in gritty feeling.

In the testing of flour, particular attention is given to physical characteristics, as color, purity as indicated by absence of dirt and fine pieces of bran, capacity to absorb water, quality of gluten and character of the bread product. For bread-making purposes, the quality of the flour depends largely upon the amount and quality of the gluten. The gluten is obtained by making a stiff dough of the flour and then washing this dough with an abundance of water, which removes the starch, leaving the gluten in the form of a gum-like mass. Gluten from high-grade flours is firm, elastic, white or of slightly yellowish tinge and possesses good qualities of expansion. Poor gluten is dark in color, sticky and lacking in elasticity. The color of the flour depends largely upon the quality of the wheat and the method of milling employed. Some wheats produce creamy or yellowish flours, others chalk white flours and others dark-colored flours. Dark-colored flours, however, produce bread of inferior quality; creamy and white flours producing the best grades of bread. The granulation of the flour is also taken as an index of its quality, as it reveals to the experienced miller and baker the character of the flour. Comparative baking tests are generally resorted to in order to determine the bread-making value of flours. By these tests, under uniform conditions with the same amount of flour, yeast, water, etc., in each case, differences in the bread-making qualities of the flour are readily revealed. When flour is stored for a long time, it sometimes becomes inferior through fermentation changes. Ordinarily, flour will not deteriorate until after it has been kept for 10 months or more. Some wheats produce flours of better keeping qualities than do others. The soundness of the wheat, as freedom from rust, smut or other blemishes, influences the keeping qualities of flour as well as does also the process of milling, particularly the extent to which the cleaning and purification are perfected.

Wheat flour is not ordinarily adulterated, although at times attempts have been made to add other cereals and mineral adulterants. The national flour law requiring all mixed flours to be branded has prevented extensive adulteration. At one time, corn flour produced by milling corn, was used for adulterating wheat flour. This, however, was only practised for a very short time when corn was cheap and wheat was high in price. The blending of wheat and corn flours has never proven successful and the practice since the passing of the national flour law has been discontinued. Wheat flour appears to be less subject to adulteration than many other articles of food. See ADULTERATION.

Wheat flour is used not only for bread making but for other purposes. Crackers, cakes, pastry and many food articles are made largely of flour. Flour is also used in the arts and industries and in various manufacturing operations. The comparative value of bread made from different kinds of flour, as graham, entire wheat and straight, is discussed in the article BREAD AND BREAD MAKING.

It is estimated that four and a half bushels of wheat, equivalent to about 200 pounds of flour, are consumed annually per capita in the United States. The consumption of flour as food has, during recent years, gradually increased. Some political economists and scientists have feared that at no distant date the consumption of flour would exceed the production of wheat. But improved methods of agriculture and the opening up of large tracts of land suitable for wheat culture, as in northwestern Canada, render this improbable. From earliest times wheat and wheat flour have taken an important part in the dietary of man and there is every reason to believe that it will continue to be one of his staple articles of food. The extent to which it should be used in the dietary depends largely upon the individual and the cost of food. Ordinarily wheat flour is one of the cheapest articles of food, and when it forms a part or even the main portion of a ration, it supplies a large amount of nutrients in a digestible form and at a low cost.

HARRY SNYDER,
Professor of Agricultural Chemistry, University of Minnesota.

Flow'er, Benjamin Orange, American editor and author: b. Albion, Ill., 19 Oct. 1858. He was for some years the publisher and editor of the 'Arena' at Boston. Among his numerous works are: 'Civilization's Inferno; or Studies in the Social Cellar' (1893); 'The New Time' (1894); 'Persons, Places, and Ideas'; 'Gerald Massey: Poet, Prophet, and Mystic' (1895); 'The Century of Sir Thomas More' (1896); 'Lessons Learned from Other Lives.'

Flower, Frank Abial, American historical writer: b. Cottage, N. Y., 11 May 1854. Has written several local histories: 'Old Abe, the Wisconsin War Eagle' (1880); 'The Life of Matthew H. Carpenter' (1883); 'History of the Republican Party' (1884).

Flower, Roswell Pettibone, American financier: b. Jefferson County, N. Y., 7 Aug. 1835; d. Eastport, Long Island, 12 May 1899. He began his business and political career in Watertown, N. Y., where he organized the Jefferson County Democratic Club. His success in politics attracted the attention of Samuel J. Tilden, through whose influence he was appointed chairman of the Democratic State Committee in 1877. Four years later he was elected to Congress, and in 1886 was appointed president of the Subway Commission. He was re-elected to Congress in 1888 and 1890, and in 1891 was elected governor of New York. From the close of his term till his death he applied himself to the interests of his large banking house and to a systematic course of philanthropy.

Flower, Sir **William Henry,** English zoologist: b. Stratford-on-Avon 30 Nov. 1831; d. London 1 July 1899. After a medical training he served as an assistant-surgeon in the English army during the Crimean war; in 1861 was appointed conservator of the museum of the Royal College of Surgeons; and in 1870 Hunterian professor of comparative anatomy in the same institution. In 1884 he was appointed director of the natural history departments of the British Museum, which two or three years before had been removed to their new quarters at South Kensington. From this post he retired in 1898. In 1889 he was president of the British Association meeting at Newcastle-on-Tyne. He was made a knight commander of the Bath in 1892. Several important treatises came from his pen, including 'Introduction to the Osteology of the Mammalia' (1870, 3d ed. 1885); 'Fashion in Deformity' (1881); 'Introduction to the Study of Mammals, Living and Extinct' (1891); 'The Horse: a Study in Natural History' (1892); and 'Essays on Museums and other Subjects connected with Natural History' (1898).

Flower, that part of the spermatophytous (phanerogamous) plant which consists of the organs of reproduction, frequently, but not necessarily, accompanied by protecting envelopes. In common usage, the word "flower" is applied to those related structures only in which one or both sets of floral envelopes are present and rather conspicuous.

Parts: Their Position and Functions.— The end of the flower stalk upon which the parts of the flower are grouped is known as the torus or receptacle. In a complete flower the floral envelopes are double, composed of two whorls or circles, alternating with each other; the outer series consisting commonly of green or greenish leaves named sepals, and together forming the calyx; and the inner series, of leaf-like parts, usually of a delicate texture, and of some other color than green, named petals, and together constituting the corolla. The term perianth is sometimes applied to the floral envelopes taken together, but it is generally restricted to those flowers in which only one of the series is present, at least in appearance, as in the lily, and in the common marsh-marigold; or in other instances where the limits of the calyx and the corolla are not easily distinguished. The organs of reproduction are the stamens, or fertilizing organs, forming a whorl within the floral envelopes and known collectively as the andrœcium; and the pistils at the centre of the flower, containing the ovules or undeveloped seeds, and known as the gynœcium. The essential part of the stamen is the anther or pollen sac, having usually two cells attached by a connectile to one another and to the stalk, called a filament, at the summit of which they are placed. The insertion or place of attachment of the stamens varies. In the lily, the buttercup, and the marsh-mallow the stamens are seen to arise directly under the gynœcium, and are accordingly described as hypogynous; in the strawberry and cherry they arise in a higher circle and upon the calyx and are termed perigynous; while in the iris, the rose, and blueberry they are inserted upon the top of the ovary, and are said to be epigynous. (Plate I., Figs. 3, 4, 5.) In the absence of the filament the anther may be sessile on the receptacle, calyx, petals, or ovary, or be adherent to the style (as in *orchis*). The essential parts of the pistil are the ovary and the stigma. The former is the rudimentary seed vessel. The latter, which is intended to receive the pollen upon its viscid surface, is connected with the ovary by a stalk known as the style, or is sessile upon it, as in the poppy. The pistil may be formed of a single carpel or of a number of carpels united by their lower parts to form a compound pistil. The number of carpels represented in such a pistil may be determined by the number of styles; by the number of free stigmas (though a single carpel is sometimes accompanied by a two-lobed stigma); by the seams, lobes, or angles of the ovary; by the cells, by the character of the placenta, or ovule-bearing portion of the carpel. The ovules, or rudimentary seeds, are borne upon the inner or ventral suture formed by the united edges of the carpellary leaf constituting the seed-vessel. In a "compound" pistil the single carpels may be closed, as in a "single" pistil, and joined at their sides and ventral sutures; or they may be open and joined by their edges. In the first case there will be in the compound ovary, as many cells as there are carpels, and the placentæ will meet at the axis. In the second there will be but one cell and the placentæ will be parietal. There are, however, many intermediate conditions, as in the poppy where the inflected margins of the carpels carry the placentæ to the centre. The apparent anomaly of a free axial placenta in the single cell of a compound ovary is found in the purslanes and in the pinks. The delicate partitions or dissepiments have very early disappeared. The ovules vary in number from one to hundreds. They are sessile or borne on a stalk called the funiculus. In direction they are horizontal, ascending (pointing obliquely upward), erect from the base of the cell, pendulous from near the top of the placenta, or suspended from the summit. The ovule-body is surrounded by an integument of one or two coats, which does not meet at the summit. The minute opening thus left is known as the micropyle. Within the ovule-body is the embryo-sac, which contains the endosperm and one or more germ-cells. The simplest form of pistil is that of the gymnosperms, which consists of open scales bearing two or more ovules on the inner face next the scales.

The chief function of the calyx is protection, an office which it shares with the corolla, especially while the more delicate organs are in the bud. When the corolla is lacking, the calyx frequently assumes some of its characteristics, becoming more conspicuous and of finer color and texture, the marsh-marigold and purple clematis furnishing examples in point. The bright hues or markings of the corolla serve to attract the insects that play such an important part in the pollination of the flower. The andrœcium has for its function the producing and scattering of the fructifying pollen, which falls from the anthers when they open at maturity. The gynœcium is devoted to the development of seed from the ovules.

Evolution of the Flower.—The recognition of the flower as a modification of the stem and leaves, adapted to the purposes of reproduction, gives a key to its morphology, throwing light on

MORPHOLOGY OF FLOWERS.—I.

innumerable variations of arrangement and structure and even on such details as scent, color, and the production of nectar. This conception of the flower was of fundamental importance in the transition from the artificial to the natural system. The shortening of the axis aggregates the transformed leaves and a growth is produced in which the arrangement of the true leaves on the stem is still the regulating principle, whether there be an alternating succession or a whorled (cyclic) grouping, the more developed flowers following the latter order, with limited number of parts, generally definite for certain large groups. Flower buds, like leaf buds, are terminal or axillary. The prefloration or æstivation of the sepals and petals, individually considered, is similar to that of leaf buds, being convolute, revolute, or involute. The metamorphosis of the leaf is easily traced in certain flowers. In the peony the transition from leaves to bracts and thence to petals is gradual, as is the change in the sweet-scented shrub (*Calycanthus*) from sepals to petals. In the white water-lily the gradations between the pistil and stamen are finely illustrated. It does not follow that the order of development is from the former to the latter. That the essential organs are of earlier origin than the floral envelopes is indicated by the fact that the latter are wanting in the gymnosperms, which are older and less developed forms than the phanerogams (spermatophytes). In the anther we recognize the infolded leaf-blade, in the filament its petiole, and in the pollen a development from the parenchyma. In the pistil the carpellary leaf may be traced, with its lengthened apex forming the style. The double-flowering cherry offers an interesting example of the reversion of the pistil to the form and color of the true leaf. The interpretation of the ovule as a transformed bud upon the edges of the carpellary leaf is confirmed by the fact that the leaves of *Bryophyllum* and certain other plants produce buds upon their margins or upper surface. Even the stipule of the leaf has its homologue in the floral structure. What is called the outer calyx or epicalyx of the strawberry may be regarded as the united stipules of adjacent sepals. That portion of the stem which becomes the floral axis sometimes undergoes striking modifications in its function as a receptacle. In the wild geranium it is extended into a slender beak, while in the rose-hip it becomes urn-shaped. The fig and the strawberry are succulent receptacles, the one hollow and the other convex. In investigating the morphology of the flower it was formerly the method of botanists to start from an ideal type and to consider as mere modifications of that type all forms that differed from it. A later view admits the probability of various independent lines of development. Those types are the simplest in which the floral structure is nearest to the original arrangement, the parts being more definitely separated. Union of parts indicates as a rule greater complexity of type, though simplicity of structure may in some cases be an indication of degeneration. Simplicity of type is illustrated by the water-lily family (*Naiadaceæ*), and complexity by the orchids (*Orchidaceæ*) and the thistle family (*Compositæ*).

Although the morphology of the flower continues to be of paramount importance in the classification of plants, the application of the principles of evolution to the study of botany has inevitably led to a method differing from that formerly in use. The 24 classes into which Linnæus divided plants were (with the exception of the cryptogams) based on the length, number and other characteristics of the stamens; and the classes were divided into orders chiefly according to the characteristics of the pistil. In the system worked out by the French botanists and known as the "natural" system stress was laid upon the characteristics of the perianth, the presence or absence of a corolla and the union or separation of petals. In a system based on the facts of development the fundamental division into monocotyledons and dicotyledons may still be maintained, though late methods do not recognize the likeness existing between adult forms as sufficient to place them in the same group, classification proceeding rather on the principle that relationship is more convincingly shown by similarity in manner of reproduction and in laws of growth.

Variation in Structure and Arrangement.— Flowers are said to be perfect when they are provided with both kinds of essential organs; complete when calyx and corolla are also present; regular when all the parts of each set are alike in shape and size; and symmetrical when they have an equal number of parts of each kind. In the monocotyledons the parts are in threes; in the dicotyledons mostly in fives or fours. The perianth of the lily, though apparently having six in a set, has really three sepals and three petals, as is plainly shown in the bud. Apparent violation of the law of symmetry may in certain cases be due to adhesion, abortion or non-development of floral plants. In the mustard family, though the calyx and corolla are in fours, the stamens are generally six. The suppression of two stamens would account for lack of symmetry. An instance of non-development is found in the monkshood, where the sepals number five and the petals two, while three very minute rudimentary petals are sometimes discernible. The violet, although symmetrical as to sepals, petals, and stamens, which are in fives, has a simple stigma and three-valved seed-vessel. The flax is a good example of a symmetrical and regular flower. The irregularity of the flower may be shown in any of its parts, but is most striking in the peculiar forms often assumed by the corolla and calyx, most curious instances being seen in the orchids, a family in which the morphology of the andrœcium and gynœcium are also of especial interest.

Certain variations of form may be traced to the visits of insects, as where such a visitant alighting always on the same side of the flower tends by its weight to increase the size of that part or to thicken the tissue, etc. The chief irregularity of some corollas consists in having one or more spurred petals. This deviation from the ordinary petal shape is common and sometimes serves the purpose of providing flowers with nectaries, as in the case of the violet, the toad-flax, and the columbine. In the nasturtium it is the calyx spur that constitutes the nectary. Less noticeable modifications in the petals of other flowers have the same function, as the scales on the petal-claws in the crowfoots and the pits in the petals of lilies and fritillaries. The irregularity illustrated in the blossoms of the pea and the bean is of a very common kind. This butterfly or papilionaceous corolla marks the family to which these legumes belong. In the case of gamopetalous (sympetalous) corollas it is convenient to speak of the parts of the more primitive or separated type as having coalesced, even if the growth be regarded as undivided from the beginning. The regular five-petaled corolla has its homologue in such a gamopetalous corolla, as that of the campanula (Plate I., Fig. 8), where the five lobes correspond to the separate petals and maintain the numerical scheme of the flower. The labiate or bilabiate (two-lipped) corolla is the characteristic form of the mint family (*Labiatæ*), and of the figworts (*Scrophulariaceæ*), the ringent or gaping corolla of the dead-nettle (Plate I., Fig. 14) and the personate corolla of the snapdragon and toad-flax being variations of the type. Not only is a union of parts frequent in the corolla and the calyx, but it has its counterpart in certain forms of the andrœcium and the gynœcium. The filaments of the lupine arise as a single cylindrical growth and the syngenesious anthers of the *Compositæ* are a pre-eminent characteristic of that large family. The combination of several carpels to form one pistil has already been referred to, complete union being found in the rhododendron among other instances, and the gynœcium takes a great variety of forms according to the degree of distinctness maintained by the separate parts of the contiguous carpels.

Fertilization.— Flowers which are achlamydeous, that is, destitute of floral envelopes, may be unisexual or bisexual (androgynous). The male (staminate) flowers and the female (pistillate) flowers may be found upon the same plant, which is then termed monœcious, the alder, oak, ragweed and begonia being examples; or the staminate flowers of a species may be produced by one plant and the pistillate by another, the plants being then diœcious, as in the willow family (*Salicaceæ*). The neutral flower is one lacking both kinds of essential organs, as is the case with the ray flowers of many *Compositæ*. The showy snow-ball tree and the garden hydrangea are examples of development of such flowers by cultivation, the neutral flowers being found only on the margin of the flower cluster in the wild species. Close fertilization, that is, the fertilization of a flower by its own pollen, is rendered impossible by the unisexual arrangement, but so long as the transfer may be from flower to flower on the same plant the advantages of cross-fertilization strictly so-called (that is, from plant to plant) are not positively insured. Diœcious flowers might be expected to prove better producers of seed, as close fertilization would naturally be looked for in bisexual flowers, and indeed was formerly considered the normal method, but it is doubtful if there is any species of which it could be proved that its flowers are without exception self-fertilized. By the dichotomy of some species of bisexual flowers (that is, by a difference in the time when the essential organs mature) the pollen is set free before the stigma is ready for pollination, the latter being accordingly obliged to rely upon pollen from without. In other cases the structure of flowers is of such a nature that fertilization by their own stamens is guarded against.

Agencies for the transportation of pollen are various. Flowers dependent upon the wind, like those of the date-palm, are known as «anemophilous»; those for which insects are the carriers are «entomophilous.» (See FLOWERS AND INSECTS.) Many plants bear two kinds of blossoms, conspicuous, nectar-producing flowers, which are entomophilous, and inconspicuous, later-blooming blossoms in which close fertilization takes place. Certain species of violets have the two forms, their later flowers never opening nor developing petals, but becoming fertilized in the bud. Contrary to the law which generally controls fertilization, these cleistogamous blossoms are more fruitful than those on the same plant open to cross-fertilization. Whatever be the method of pollination, the pollen-grain when it falls upon the stigma absorbs the moisture of the surface and germinates. It then sends down a tube which passes through the tissues of the style and stigma and on reaching the cavity of the ovary enters the micropyle and penetrates to the embryo sac. Sometimes the latter has grown out to the micropyle, or even through it, to meet the pollen-tube. The chalaza, or point of attachment of the ovule, is in a few instances the place of entrance for the pollen-tube. The transfer of the contents of the pollen-tube to the germ-cell in the embryo sac takes place, thus fertilizing the cell, which begins to grow and divide, developing the embryo plant, at first nourished by the endosperm, or albuminous contents of the sac.

Colors of Flowers.— The colors of flowers have been arranged in two series, the blue and the yellow, in both of which red and white are found, green being produced by a blending of the two. It has been estimated that in an average collection of 1,000 plants about 284 have white flowers, 226 yellow, 220 red, 141 blue, 73 violet, 36 green, 12 orange, 4 brown, and 2 black. White flowers are more generally odoriferous than those of other colors, and their odors are almost always agreeable. Red flowers, though less numerous than yellow ones, are more often fragrant. The tints are due to fluid or viscous matters contained in superficial cells and can be separated in certain cases by solution in water and in others by solution in alcohol and ether. Attempts have been made to refer the coloring matters to one or two principles, which have been described under the names of xanthin, xanthein, anthoxanthin, and cyanin and anthocyan. These bodies, however, are very ill defined and are in all probability mixtures, even supposing that when obtained from different sources they are essentially the same. The chief difficulty is to obtain the coloring matters in sufficient quantity for investigation and then to separate them accurately from each other which, as they are amorphous, uncrystallizable bodies, is not easy to accomplish satisfactorily. Of the coloring matters from flowers one of the most individualized is the yellow body obtained from saffron. See BOTANY; FLOWERS AND INSECTS; FRUIT; GARDEN; INFLORESCENCE; SEED.

Flower Beetles, scarabeid beetles of several genera One of the most abundant and destructive of these insects is the rose-chafer (q.v.), which annually does great damage to roses and other flowers and fruits. Several species of the genus *Euphoria,* more especially *E. inda,* is frequently found on flowers eating pollen, but it also attacks corn in the milk, and eats into various forms of fruit. Other flower beetles belonging to the genera *Hoplia* and *Trichius* are commonly found on flowers through-

out the country and take some part in the cross-fertilization of useful plants. Numerous other beetles frequent flowers, among which are beautiful species of the genera *Clerus* and *Trichodes* of the *Cleridæ; Leptura* and many related genera of long-horned beetles; and many genera of small families such as the *Mordellidæ.*

Flower-bug, a very minute bug (*Triphleps insidiosus*) also called "insidious flower-bug," and related to the bedbug. It is found on the foliage of various plants, and preys upon other minute insects.

Flower Month, in general any month in any country in which flowers are springing most abundantly; in the United States, June is specially the month of flowers. Specifically, the month Anthesterion, the eighth of the Attic year, corresponding nearly to February; so called because that time was, in that country, the season of flowers.

Flower-peckers, general name for a large family (*Dicæidæ*) of small insectivorous birds allied to the creepers (q.v.) which get their food largely by searching flowering plants and their blossoms, picking up minute insects largely by aid of a curious tongue which is separated at the end into four tubular projections. They inhabit the Indo-China region and thence throughout the archipelagoes to Australia, where the white speckled diamond-birds (*Pardalatus*) and the swallow-dicæum (*Dicæum erythrorhynchum*) are familiar friends of the gardener. They frequent bushes and trees, hopping briskly about the branches, and creeping and clinging like titmouses. Some make extremely beautiful, highly decorated nests, while others are content to deposit their eggs, which in most of the species are white, in holes in trees, or earthen banks, or old birds' nests. Some are plainly dressed, but most of the flower-peckers are gaudily colored, and several sing sweetly.

Flowering Ferns. See *Filicales* (1), under FERNS AND FERN ALLIES.

Flowers, in chemistry, a term formerly applied to a variety of substances procured by sublimation in the form of slightly cohering powder, hence in all old books we find mention made of the flowers of antimony, arsenic, zinc, and bismuth, which are the sublimed oxides of these metals in a more or less pure state. We have also still in use though not generally the terms flowers of sulphur, of benzoin, etc.

Flowers and Insects: Their Relations. In order to appreciate the intimate relations between flowers and insects we should bear in mind the fact that in all probability the earliest plants known were flowerless, and that the earliest known insects never visited flowers. The most primitive reproductive parts of plants were minute structures, simply greenish, and without colors. From the cryptogamous plants somehow arose the flowering plants, and when flowers did appear, they were of regular shape, with the corolla made up of separate petals: then finally appeared the irregular flowers like those of the monkshood, the pea, bean, wistaria, etc. The simpler forms of flowers were those of the grasses. Such plants are fertilized by the wind, but in the higher modern flowering plants the floral organs are fertilized by insects. What attracts insects to flowers, and thus causes them to carry the pollen from the stigmas to the pistil? Is it the nectar or the odor given out by the flower, or the colors of the petals?

Insects Attracted by the Sweets of Flowers. — According to Darwin, Lubbock, and others, the brightly colored petals of flowers are necessary to attract bees, butterflies, moths, beetles, etc. Thus the petals of many flowers are beautifully marked with highly colored hues, which are thought to be "guiding lines," by which the bee was guided to the nectary at the bottom of

A hawk-moth sucking nectar from a tiger-lily.

the flower. But this view has been called in question by a Belgian naturalist, Plateau. To test the matter Darwin and others had removed the petals, or corolla, and watched to see whether insects continued to visit the flower, but this, owing to want of care in removing the petals, had led to contradictory results. Plateau experimented more carefully; he avoided handling the flowers, or doing anything which might influence an insect's sense of smell. He removed the brightly colored corollas from the flowers of lobelia, ipomæa, larkspur, foxglove, etc., and in every case, except that of *Antirrhinus majus,* the mutilated flowers were observed to be freely visited by various kinds of insects (bees, bumblebees, syrphus flies, and an occasional butterfly), no special preference being exhibited for flowers that were left intact. The insects not only sucked honey from the mutilated flowers, but they often circled around them without alighting. In the case of the snapdragon, several bumblebees hovered around the mutilated heads but afterward left them for those with entire flowers, a result explained by the peculiar mode in which bees have to enter the corolla, which would render the absence of that structure perplexing to them. Plateau covered several of the large umbels of Hieracium with rhubarb leaves, when it was found that even when thus masked they were freely visited by insects. The result shows that insects are in reality guided to flowers in the great majority of cases by their sense of smell, the scent of the nectar attracting them. Some insects, as the white cabbage butterfly, are attracted by the white color of the flowers they visit, and yellow butterflies by yellow flowers. Undoubtedly some butterflies and moths have the color-sense, but probably those insects such as beetles, bugs, etc., which are most concerned in fertilizing flowers, are attracted by the odors emanating from the nectary and glands of such flowers.

Of flower-haunting flies (*Diptera*) the color-sense is shown in the case of certain higher types of flies which prefer red and blue flowers, and they oftener visit the more complicated kinds of flowers than do the smaller bees. These flies seem to possess greater importance for the function of pollination than previously supposed. In Africa some kinds of orchids are fertilized by flies.

It thus appears that though the colors of some flowers attract certain insects which have the sense of color, the most efficient insect-aids to fertilization of flowers are those which are attracted mainly if not solely by smelling the nectary or odor of the flower.

Plateau indeed claims that any flower is freely visited by insects if it be nectariferous, no matter how colorless or inconspicuous it may be. There are, on the other hand, flowers which seem to be wholly avoided by insects, many of which are gay and attractive enough in their

Bee rifling a blossom.

shapes and colors; but when Plateau placed nectar at the base of these flowers, visits of insects were at once begun. Meehan states that in the United States a single plant of the common sumac (*Rhus glabra*) was growing in an isolated spot almost hidden by other vegetation, and far away from any flowers visited to any great extent by insects. The flowers of this shrub are small, green, entirely inconspicuous, and so far as human olfactories go, odorless. But he observed an extraordinary number of kinds of insects visiting the flowers. He infers that this remarkable collection of insects, including honey-bees and wasps, could only have been guided by the sense of smell, and he infers that all plants with nectar have odor, though it may not be strong enough to be perceptible to man.

The nectary is a specially modified scent-gland, and the nectar is a specialized form of the sap or juice of the plant. As stated by Henslow, the nectaries probably originated from the visits of insects, and the local irritation set up by these visits gradually led to the origination of the glandular secreting organ called the nectary. When the entire flower degenerates and becomes self-fertilizing, not needing the help of insects, the nectary also disappears. Ant-plants are so-called because they are due to the modifications occasioned by the visits of ants.

Fertilization of Flowers by Insects.— We have seen that insects are strongly attracted to flowers by smelling the sweets secreted by glands or nectaries. How important this nectar is to bees is proved by the fact that the honey they produce is nectar changed to honey in their digestive organs. Many insects subsist on the pollen of plants; such are bees of all kinds which use it in making bee-bread as food for their young; multitudes of wasps, flies, and beetles gather also the pollen of flowers, and eat it, this being their only food, or they store it up as nourishment for their young.

Their visits to flowers result in their carrying the pollen from one flower to another, and thus fertilizing the plant. Hence owing to the visits of honey-making bees, of wasps, of moths, and butterflies, and of pollen-eating flies and beetles, the flowers become indirectly fertilized, and were it not for their visits, such flowers would be sterile, and the species die out.

As early as 1793 Sprengel discovered the main facts and many details as to the relations between flowers and insects. As Wallace states, he noticed the curious adaptation of the structure of many flowers to the particular insects visiting them; he proved that insects cross-fertilize flowers, and that the presence of nectar and pollen ensured the continuance of their visits. Afterward it was shown that cross-fertilization of plants was a benefit to them, while Darwin (saying that "nature abhors perpetual self-fertilization") proved that this was a general occurrence not only among ordinary plants but with orchids. It thus appears that insects have been the cause of, and are the means of maintaining, the present wealth of flowers which enliven the tropical forests, and adorn our northern gardens and fields.

Colors of Flowers and the Visits of Insects.— Although it is generally claimed that sweet odors are, as Wallace says, usually supplementary to the attractions of color, yet this view, as we have seen, will have to be modified. Gaudily colored flowers, like the sunflower, poppies, and peonies, are nearly scentless compared with plants like the mignonette, which are so fragrant. White flowers are fertilized by moths, and very frequently give out their scent only at night, as in the case of the butterfly-orchis. Bright red flowers are very attractive to butterflies, and are sometimes specially adapted to be fertilized by them, as many kinds of pinks, the corn-cockle, etc. Blue flowers are especially attractive to bees and other hymenoptera, as many as 67 species having been observed to visit the common European sheep's bit. Dull yellow or brownish flowers, some of which smell like carrion, attract flies, while the dull purplish flowers of the Scrophularia attract many wasps. (Wallace.)

It is interesting to learn that many change their colors as soon as fertilized; in this way bees avoid wasting their time in visiting such flowers as have already been fertilized and their nectary exhausted. The common lung-wort is at first red, but afterward turns blue. In southern Brazil grows a species of Lantana whose flowers are yellow the first day, orange the second, and purple the third, while F. Müller observed that many butterflies visited the yellow flowers only, some both the yellow and the orange flowers, but none the purple. Moreover many flowers have been specially adapted to the kinds of insects that most abound where they grow. Thus in the Swiss lowlands the gentians, although with us they flourish in the White Mountain region, are adapted to bees, but those of the high Alps to butterflies only, as this zone is the home of Alpine butterflies. The visits of insects to flowers in fine weather are incessant and hence economy of time is, as Wallace states, very important both to the insects and the flowers, because the fine working days are comparatively few. For example, bees keep to one flower at a time, visiting hundreds of blossoms in succession; they thus acquire quickness in going at once to the nectary, and the change of color in the flower, or incipient withering when fertilized, enables them to avoid those flowers that have already had their honey exhausted.

Perforation of Flowers by Bees.— If one will watch a wistaria when in blossom, he will notice that the bumblebees, in order to get at the nectar without loss of time, perforate the corolla right over the nectary, and thus speedily rifle the flower of its sweets. So well trained is the bee that the hole is always made right opposite or over the nectary. On the other hand the honey-bee, with its shorter and weaker maxilla, cannot make a hole through the walls of the corolla, but partly enters the flower on one side or the other and with more or less trouble laps up the nectar. At the end of the season, provided bumblebees are plenty, nearly every flower on a large vine will be found to have been perforated. Similar flowers, as the clover, touch-me-not, etc., are thus perforated. Lovell states that the maxillæ alone are employed in this act, being moved slowly backward and forward in puncturing the tissue. Thus the stout strong maxillæ of the bumblebee are adapted for this purpose.

Click-beetle and orchid.

Irregular Flowers due to Visits of Insects.— It is now thought by some observers that owing to the strains, pressure, and irritation caused by the visits of insects, flowers like those of the pea, bean, etc., have been formed. Henslow points out that the lower petal or lip of these irregular flowers forms a platform on which the bee rests while engaged in probing the corolla for nectar. In the irregular flowers of the foxglove, petunia, etc., the tube of the corolla has enlarged so as to allow the ingress of an insect which partly crawls into it, hence the tubular corolla having to bear the strain upon it bulges outward, while the lip or anterior petal is not much if at all enlarged. Even if, says Henslow, no more than the head of an insect enter the flower, then the corolla shapes itself to fit it. He explains the formation of the deep tubular corolla of the evening primrose or the honeysuckle by the fact that butterflies, in probing their depths while on the wing, irritate the tube only, which is thus made to become longer and correspondingly to contract in diameter, the result being that there is but little irregularity in the shape of the flower. The immediate mechanical cause of the shape of the wing-petals of many pea-blossom-like flowers is probably due to the weight of the insect in front, the local irritations believed due to the thrust of the insect's head and its probing for nectar, united with the absence of all strains upon the sides. An example of the great thickening of the tissue just where the strain will be most felt is the flower of the lady's slipper and Calceolaria.

Origin or Modification of Insects by Flowers. — We have seen that flowers attract insects by means of their nectar and sweets and also their pollen; that the visits of insects are in favorable days practically incessant, though owing to the weather more or less intermittent; the result seems to be that the forms of insects, especially of their accessory jaws (maxillæ and labium), as well as of their legs, are wonderfully adapted to their habits. It is not improbable that by these simple mechanical causes, that is, the use or exercise of the parts concerned in gathering pollen and nectar, a number of groups of insects (bees, certain flies, and the moths and butterflies, and certain families of beetles) have been brought into existence. We know that in all probability flowers and the insects which visit them, came into existence after the coal period, owing to the reaction of flowers upon these kinds of insects, causing the exercise and modification of the structures actively employed in collecting pollen. Among the flower-visiting flies and beetles the proboscis of the former, and the maxillæ of the latter, are wonderfully adapted for scraping off the pollen from the anthers of flowers.

ALPHEUS S. PACKARD.
Late Professor of Zoology, Brown University.

Flowers, Artificial, flowers made from various materials to imitate natural blossoms. These are not a modern invention. The famous floral wreaths made by the ancient Egyptians were formed from thin plates of horn stained in different colors, sometimes also of leaves of copper, gilt or silvered over. The Romans excelled in the art of imitating flowers in wax and in this branch of the art attained a degree of perfection which has not been approached in modern times. Crassus, renowned for his wealth, gave to the victors in the games he celebrated at Rome crowns of artificial leaves made of gold and silver. In modern times the Italians were the first to acquire celebrity for the skill and taste they displayed in this manufacture, but they are now far surpassed by English and French manufactures, more especially by the latter.

The first artificial flowers made in modern times in civilized countries were manufactured out of many-colored ribbons which were twisted together and attached to small pieces of wire. But these first attempts were decidedly crude. In course of time feathers were substituted for ribbons, a more delicate material, but one to which it was not so easy to give the requisite shades of color. The plumage of the birds of South America is admirably adapted for artificial flowers on account of the brilliancy and permanence of the tints, and the natives of that continent have long practised with success the making of feather flowers. The Zoological Gardens in Regent's Park, London, contain a magnificent collection of artificial flowers made out of the feathers of humming-birds. In South America artificial flowers are also composed of the wing cases and other parts of some brilliant specimens of beetles. In Italy the cocoons of silkworms are frequently used for the purpose, as these take on a brilliant color and have a velvety appearance. Among the other materials used in this manufacture are cambric, muslin, satin, velvet, and other woven fabrics, blown glass, mother of pearl, brass, thin layers of whalebone, etc., beside the various vegetable and mineral coloring matters. Flowers were at one time made of porcelain and were perfumed. Great skill has been attained in the making of glass flowers and a remarkable collection of this kind is owned by Harvard University.

Flowers, Symbolism of, a special significance attached to flowers by means of which they are made to represent various ideas and sentiments. This mode of communicating thought has developed in certain countries into a language of remarkable elaboration. Among the Greeks and Romans the use of flowers was full of significance. Though the well-developed floral speech of the Romans was probably lost to a great extent, the study was revived in Europe during the Middle Ages, being especially appropriate in connection with such a romantic institution as chivalry. The Orientals have developed the language of flowers into a vehicle for communicating sentimental and amatory expressions of all degrees of warmth. Still further complexity is added by the habit of employing flowers the Turkish or Arabic names of which rhyme with the other really significant words. The language of flowers is, of course, arbitrary, and a bouquet which a Persian girl would understand would be unintelligible to an Egyptian inmate of the harem. Yet among European nations certain flowers have a common significance. The rose is widely accepted as the symbol of love and beauty; the forget-me-not of true love; the lily of purity; the violet of modesty; the daisy and white violet of innocence; the rosemary of remembrance; the amaranth of immortality; the asphodel of death and the unseen world; the pansy of thought; the hyacinth of sorrow; the narcissus of self-admiration; the poppy of oblivion. The almond expresses hope; the lily-of-the-valley unconscious sweetness; the wallflower, love faithful in spite of adversity; the primrose, early youth; and the cyclamen, diffidence. So surely as the orange-blossom is associated with marriage does the finding of white heather betoken good-fortune to come, while the future chances of love may be revealed from the daisy and poppy by a simple method of divination The laurel has long been accepted as the emblem of glory, and the oak of patriotism. In the Grecian games wreaths were placed upon the brows of the victors, but these were of leaves rather than blossoms. Floral garlands were much used at the feasts of the ancients, and in India it is customary to show special honor to a guest by encircling his neck with a wreath of flowers. Historical and national associations cluster about certain flowers. The violet was the flower of Athens. The red and the white roses of Lancaster and York gave name to a great civil war. Particular families and clans have their floral badges and there are national and heraldic emblems drawn from the floral kingdom, such as the rose of England, the thistle of Scotland, the shamrock of Ireland, and the fleur-de-lis (q.v.) of France, the latter being associated for centuries with the royal crown. The pomegranate became a Spanish national emblem having previously been the emblem of Moorish Granada. In Japan, the chrysanthemum is the flower of the nation, and in India the lotus has an especially sacred significance, as it had formerly in Egypt. In the latter country it often figured in architecture. In the decorative art of India it is represented in bronze and in paintings in connection with divinities or exalted sages. The cactus is the national emblem of Mexico. No flower will ever become the national emblem of the United States in the manner in which such floral emblems have become connected with other nations, but an attempt has been made to gain an expression of popular opinion on the subject of a national flower and the golden-rod appears to lead in the contest, as it has done in the case of the Empire State, of which it has been chosen as an emblem. The legislatures of certain States have taken action on the choice of a State flower, Utah selecting the seg lily; Vermont, the red clover; Oregon, a native grape; Nebraska, the golden-rod; Michigan, the apple-blossom; Maine, the pine tassel and cone, and Iowa the wild rose. In England what may be called a party emblem is illustrated in the adoption of the primrose, generally known as Lord Beaconsfield's flower, by the Conservatives. Before the «Hundred Days» in French history, the violet was used by the adherents of Napoleon I. to symbolize the hope of his return from exile.

Floyd, John Buchanan, American statesman: b. Smithfield, Montgomery County, Va., 1 June 1807; d. near Abingdon, Va., 26 Aug. 1863. He was educated at Columbia College, S. C., graduating in 1829. Studied law and settled in southwest Virginia. Was a member of the Virginia legislature several terms, and was governor of the State 1850–3, his term being notable for his advocacy of the policy of public im-of war in the cabinet of President Buchanan, provements. In 1857 he was appointed secretary and remained in it until 29 Dec. 1860, when he resigned because he considered the action of Maj. Anderson in occupying Fort Sumter a breach of faith to South Carolina. He went to Abingdon, Va. On 29 Jan. 1861 the grand jury of the District of Columbia indicted him as privy to a defalcation in the Department of the Interior. He returned to Washington, gave bail and demanded a trial, and the government thereupon, on 7 March 1861, entered a *nolle prosequi.*

After his departure he was also accused of having transferred arms from Northern to

Southern arsenals in order to arm the South for the Civil War. This charge was investigated by a Congressional committee, which, on 18 Feb. 1861, made a report showing it to be groundless, the arms transferred having been condemned arms, removed in order to make room in the Northern arsenals for modern ones.

In the summer of 1861 he was appointed a brigadier-general in the Confederate army, and raised a brigade which served in West Virginia until ordered to join the army of Gen. A. S. Johnston in the West. He was sent to Fort Donelson, arriving there after fighting had begun. When surrender was discussed, he transferred the command to Buckner and extricated his brigade; in consequence of which he was removed from command by Jefferson Davis. The State of Virginia thereupon appointed him a major-general in its service.

Floyd, William, American statesman: b. Brookhaven, Long Island, N. Y., 17 Dec. 1734; d. Weston, Oneida County, N. Y., 4 Aug. 1821. He entered political life as a delegate to the Philadelphia congress of 1774. The next year he was appointed a delegate to the first Continental Congress, and continued by successive reappointments a member of every Continental Congress up to 1782 inclusive. From 1777 to 1788 he also was a State senator under the first Constitution of New York, and in the Presidential elections of 1792, 1800, and 1804 was a Presidential elector.

Flück'iger, Friedrich August, ow'goost frēd'rɪʜ, German pharmacognosticist: b. Langenthal, Switzerland, 1828; d. 1894. He was educated at Berlin, Ban, Geneva, and Heidelberg, became president of the Swiss Association of Apothecaries in 1857, and in 1881 was member of a committee appointed to revise the pharmacopœia of the German empire. He wrote, in conjunction with Hamburg, 'Pharmacography: A History of the Principal Drugs of Vegetable Origin met with in Great Britain and British India' (1879), and works in German and French on the nature and history of drugs.

Flue. (1) A passage for the conveyance of the volatile results of combustion from the fireplace to the open air, or into another passage; a smoke duct, a chimney; one of a cluster of smoke ducts in a stack of chimneys. Also a passage in a wall for the conveyance of heat from one part of a building to another. (2) In music, one of the divisions of organ-stops, so called because the sound is produced by the wind passing through a fissure, flue, or windway, and striking against an edge above. (3) In a steam-engine, a pipe for the conveyance of the caloric current through a boiler, to heat the surrounding water. It is usually secured in the sheets of the fire box and smoke box respectively, as in the locomotive.

Fluel'len, a humorous character in Shakespeare's play 'Henry the Fifth.' He is a disputatious little soldier, pugnacious, and as voluble as his Welsh accent permits him to be when attempting to speak English.

Flü'gel, Johann Gottfried, yō'hän gōt'frēd, German lexicographer: b. Barby on the Elbe 22 Nov. 1788; d. Leipsic 24 June 1855. He spent many years in the United States prior to 1820 in business, diplomatic and official occupations, and became professor of English in the University of Leipsic in 1824. He compiled a 'Complete English-German and German-English Dictionary' (1830), besides publishing 'A Series of Commercial Letters' (9th ed. 1874); 'Practical Handbook of English Business Correspondence' (9th ed. 1873); 'Triglot; or Mercantile Dictionary in Three Tongues — German, English, French' (2d ed. 1854); and other useful manuals, all revised, or brought down to contemporary needs, by his son.

Flügel, Otto, German philosopher: b. Lützen 1842. He studied at Schulpforta and Halle, and took up pastoral work; was made editor of the 'Zeitschrift für exacte Philosophie im Sinne des Neueren Philosophischen Realismus,' and in 1894 was one of the founders of 'Zeitschrift für Philosophie und Pädagogik.' He supports Herbartian realism, as opposed to New-Kantian speculations, yet he believes in the necessity of a revelation. Among his works may be mentioned: 'Die Spekulative Theologie der Gegenwart'; 'Das Ich und die sittliche Idee im Leben der Völker' (1892); 'Über die persönliche Unsterblichkeit' (1902).

Flüg'gen, Gis'bert, German painter: b. at Cologne 9 Feb. 1811; d. Munich 3 Sept. 1859. In his youth he learned the manufacture of novelties in his native town, and in 1833 began his art studies at Munich, which he made his permanent home. He is a German counterpart of Hogarth and Wilkie, whom he rivals in masterly grouping and life-like expression, while in the technique of the brush he excels them both.

Fluid, a substance devoid of rigidity, or whose modulus of rigidity (see Elasticity) is zero. The word includes both gases and liquids, since these bodies, while resisting compression, offer no sensible resistance to change of form, but yield continuously and without limit to any force which tends to alter their shape while leaving their volume constant. The word "fluid" is also figuratively applied to other things which may be conveniently represented to the mind as fluids, even though it is known that they are not such. We speak, for example, of the "electric fluid," thereby meaning electricity, whose motions and general properties are known to conform to certain differential equations that are strongly suggestive of those governing the motions and properties of true fluids. This figurative use of the word is now avoided b the best writers, because, while it is convenient from certain points of view, it connotes properties that the things that it stands for do not possess. It dates from the time when electricity, magnetism, nervous energy, and certain other obscure manifestations of nature were actually believed to be due to imponderable fluids that were supposed to have a real, objective existence. See Critical Point; Elasticity; Gas; Gases, Kinetic Theory of; Liquid; Matter; Thermodynamics; etc.

Fluid Lens, in optics, a lens in which a liquid is imprisoned between circular glass disks of the required curvatures. Attempts to obtain achromatism have been made by using metallic solutions and other liquids having a higher dispersive power than flint glass.

Fluke, or Pole Flounder, a fish, one of the smaller deep-water flounders (*Glyptocephalus cynoglossus*), common near both coasts of the North Atlantic, caught by means of beam-trawls in great quantities, and highly prized as food, especially in Great Britain, where it is considered little inferior to the sole. It is the "craig fluke" of Scotland. See FLOUNDER.

Fluke-worm. See DISTOMA; TREMATODEA.

Flume (Latin *flumen*, stream), an artificial channel or conduit used to convey water for power development, hydraulic mining and irrigation. Flumes are commonly built of wood, but may be of steel and are placed above ground, frequently over trestles. See IRRIGATION; LOGGING; MINING.

Flu'or-spar. See FLUORITE.

Fluores'cence, that property of certain bodies in virtue of which they become self-luminous when exposed to light of certain wave-lengths. All bodies reflect a part of the incident light, but fluorescence is more than a mere reflection, as may best be shown by an example. "Canary glass" (glass colored slightly with oxid of uranium) exhibits a beautiful yellowish-green surface color when well illuminated, and for this reason it is much used for the production of ornamental effects. If a ray of sunlight be admitted into a darkened room through a piece of cobalt glass that is so dense that the feeble violet light that it transmits is barely visible, the canary glass shows its yellow-green color brilliantly when placed in its path. This shows that the phenomenon is not simple reflection, and further evidence of the same sort may easily be had. Glass that is tinged brownish-yellow by oxid of gold is almost perfectly transparent to the golden light from the canary glass, but if the violet light from the cobalt glass is caused to traverse the gold-oxid glass before striking the canary glass, the fluorescence is no longer observed. Furthermore, light that has passed through one piece of canary glass is incapable of exciting fluorescence in a second piece. These and other equally remarkable phenomena indicate that a fluorescent substance absorbs a portion of the light that strikes it, modifies it profoundly in some manner, and then radiates it again. Stokes has shown that the modification consists in increasing the wave-length of the incident light; and it is now known that fluorescent light invariably has a greater wave-length than the primary light that excites the fluorescence. This fact has an important bearing upon many of the phenomena of physics. When it had been determined, for example, that the "X-rays" differ from ordinary light merely by having a very different wave-length, the question whether their wave-length is longer or shorter was immediately answered by the fact they can excite brilliant fluorescence. Knowing that the X-rays are either too long or too short to affect the eye, and knowing also that fluorescent light always has a longer wave-length than the light that excites it, it follows at once that the X-rays have a shorter wave-length than ordinary light.

Many substances exhibit fluorescence to a greater or lesser degree. An aqueous infusion of horse-chestnut bark shows it brilliantly, and so also does a solution of sulphate of quinine. Certain of the coal-tar colors (q.v.) are conspicuously fluorescent, fluorescein taking its name from this fact. Kerosene is fluorescent, and sometimes strongly so. Most fluorescent substances cease to emit light almost instantaneously when the incident light is cut off from them. Some, however, such as calcium tungstate and the sulphids of calcium, barium, and strontium, continue to emit their rays for a sensible time, fading gradually away into darkness after the incident light ceases to excite them. Instruments consisting of screens that are coated with some fluorescent material and protected from ordinary light by shields, or by enclosure within a light-tight box, are known as "fluoroscopes," and are used for studying the X-rays (or Röntgen rays), and the shadows cast by them. It is to be observed that fluorescence differs from phosphorescence (q.v.) not only because it is usually of very short duration, but primarily because it is induced by the exciting action of light-rays. Phosphorescence may be due to very different causes. The light emitted by phosphorus, for example, is probably due to the slow oxidation of that substance. That which is observed in the ocean at night, and in connection with various fungi and insects, is due to causes which are more or less obscure; but in any event these various phosphorescent phenomena are quite different from true fluorescence. The name "fluorescence" was coined by Sir George G. Stokes in 1852, from the fact that the mineral fluorite sometimes exhibits the phenomenon. Previous to 1852 fluorescence was known as "epipolic dispersion." Consult: Tait, 'Light'; Preston, 'The Theory of Light.'

Flu'orides. See FLUORINE.

Flu'orine, a gaseous, non-metallic element, possessing properties resembling those of chlorine, and exhibiting powerful chemical affinity. It occurs abundantly in nature, notably in the minerals fluorite and cryolite, from the former of which it takes its name. The elementary character of fluorine was first recognized by Ampère and Davy about 1810; but although many attempts were made to isolate it, none was certainly successful until 1887, when Moissan succeeded in preparing it in the elementary state by electrolyzing a solution of hydrogen potassium fluoride, HF.KF, in perfectly anhydrous hydrofluoric acid, the solution being contained in a platinum vessel whose temperature was maintained at 10° F. below zero, and the electrolysis conducted by means of 20 Bunsen elements connected in series. When thus prepared fluorine is a gas, variously described as colorless, or as of a light greenish-yellow color. Many of the elements take fire when immersed in it, and burn with the formation of the corresponding fluorides. Water is decomposed by it, with the formation of hydrofluoric acid, HF, and the liberation of ozonized oxygen; and in fact fluorine appears to combine with all known elements except oxygen and carbon, and argon, helium, and the other recently discovered inert gases of the atmosphere. Fluorine has the chemical symbol F, is a monad, and has an atomic weight of about 19. Few of the physical properties of the element are yet known, on account of the difficulty of handling it. It corrodes glass rapidly, for example, and for this reason glass vessels cannot be used in experimenting with it.

Fluorine combines with hydrogen directly even in the dark, the compound, HF, that is formed being known as hydrofluoric acid. Hydrofluoric acid is more conveniently prepared by means of the action of strong sulphuric acid upon the mineral fluorite (calcium fluoride, CaF_2). The reaction is as follows: $H_2SO_4 + CaF_2 = 2HF + CaSO_4$. Hydrofluoric acid is a colorless gas at ordinary temperatures and pressures, fuming strongly in the air. It condenses at 5° F. below zero to a colorless, mobile liquid having a specific gravity of about 0.988, and boiling, at ordinary atmospheric pressure, at 67° F. As thus prepared, liquid hydrofluoric acid contains traces of water; but these may be removed by electrolysis, the liberated fluorine combining with the water as noted above, and the oxygen of the water escaping in the free state. When the water has all been eliminated, electrolysis ceases. The commercial importance of hydrofluoric acid depends upon the fact that this substance attacks glass so freely that it must be prepared and stored in vessels of lead or rubber. It is much used for etching upon glass, the reaction between the glass and the acid being $4HF + SiO_2 = 2H_2O + SiF_4$; the acid attacking the silica of the glass, with the formation of water and a gaseous compound of silicon, known as silicon tetrafluoride. When silicon tetrafluoride is passed into water, it is decomposed according to the equation $3SiF_4 + 4H_2O = 2H_2SiF_6 + H_4SiO_4$; the substance represented by the last term in this equation, silicic acid, separates out as an insoluble precipitate, while the compound H_2SiF_6, known as hydrofluo-silicic acid, remains in solution. Hydrofluo-silicic acid forms salts which are known as silico-fluorides. Potassium silico-fluoride, K_2SiF_6, is one of the few potassium compounds that are insoluble in water.

Liquid anhydrous hydrofluoric acid does not attack glass, but the action is vigorous when traces of water are present. The diluted acid is therefore used in practical etching, the article that is to be treated being immersed in it, after the parts that are not to be attacked have been protected by a coating of wax, or of a special "etching varnish." Hydrofluoric acid in aqueous solution acts very similarly to hydrochloric acid, forming salts which are known as fluorides; hydrogen being liberated when the acid acts upon a metal, and water when upon an oxid.

Fluorite, or **Fluor Spar,** a native fluoride of calcium having the formula CaF_2, crystallizing in the isometric system with cubical habit, and also occurring massive. It has a hardness of 4. and a specific gravity varying from 3.00 to 3.25. It has a vitreous lustre, and is transparent to subtranslucent, varying in color from white through yellow, green, red, blue, and brown. The green and violet-blue varieties are most common, and the red is rare. Certain specimens exhibit a bluish fluorescence (q.v.), and the mineral develops differences of electrical potential under the influence of heat and of light. Fluorite occurs in England, Germany, and many parts of the United States, and the commercial supply comes chiefly from Kentucky, Illinois, Arizona, Tennessee, and New Hampshire. It is a chief source of fluorine and hydrofluoric acid (see FLUORINE), and is also used as a flux for promoting the fusion of certain refractory minerals, deriving its name from this latter circumstance (Latin, *fluor*, a flow). Colorless specimens have been used for the manufacture of lenses, for which they are well adapted on account of their small dispersion.

Fluor'oscope. See FLUORESCENCE.

Flürsheim, Michael, mēи'ä-el flürs'hīm, German social reformer: b. Frankfort-on-Main 24 Jan. 1844. He emigrated to the United States in 1867, and resided there for five years. He then returned to Europe and established an iron foundry in Gaggenau, Baden (1888). Since 1892 he has lived at Castagnola, near Lugano, Switzerland, engaged in disseminating his ideas through his writings. He believes private property is the cause of immense wealth to some and profound poverty to others, and advocates the government possession of land. His works are: 'Auf friedlichem Wege' (1884); 'Deutschland in 100 Jahren' (1894); 'Papst und Sozialreform' (1891); 'Der Einzige Rettungsweg' (1894); 'Rent, Interest, and Wages' (1891).

Flush'ing, Netherlands, a flourishing seaport town in the province of Zeeland, on the south coast of the island of Walcheren, at the mouth of the West Schelde. It has long been a place of importance, but has few buildings or institutions of note. The town-house is a roomy, suitable edifice; the exchange is a simple building, and near it is a statue, erected in 1841, of Admiral van Ruyter, born in Flushing in 1607. The inhabitants are chiefly engaged in commerce, for the encouragement of which much has been done in recent times by the construction of docks, etc. Flushing has suffered several times from fire, water, and war, and in 1809 was bombarded by a British fleet, under Lord Chatham. Pop. (1901) 18,893.

Flushing, N. Y., a former village on Long Island, now a part of the borough of Queens, New York. It was settled in 1645 and was called Vlissingen.

Flute, a musical wind instrument, consisting of a tube furnished with a number of holes in it for the purpose of varying its sounds. The oldest form of the English flute had seven holes which could be stopped by the fingers, but it had no finger-keys. This was in use till about the beginning of the 18th century, when it gave place to the German flute, an instrument which, in its best form, was 27 inches in length, consisted of 4 pieces fitting into one another, and had 6 finger-holes for the normal tones, and from 6 to 12 keys for the semitones, with a compass of nearly 3 octaves, counting from middle C upward, the higher octaves being obtained by overblowing. The improvements made on this instrument, by Böhm, a German, acting in conjunction with Gordon, an Englishman, enable the player to perform music on any key, with all the chromatic intervals. The chief improvement consisted in the application of a system of keys, by which several holes could be stopped at one time, by one movement of the finger. The flutes made by Böhm are now taken as the models by most makers in all countries. In modern flutes the number of keys varies. The materials of which flutes are made are box, ivory, ebony, silver, glass, and a kind of red ebony.

Fluted Scale. See SCALE INSECTS.

Fluting, in architecture, channels or furrows cut perpendicularly in the shafts of columns, particularly Doric, Ionic, and Corinthian.

It seems probable that this kind of ornament had some relation to the original type; perhaps the furrowed trunk might have suggested the idea. It is, however, a beautiful ornament, which is applied with equal happiness to break the otherwise heavy mass of a Doric shaft, or to obviate an inconsistent plainness in the other orders. When the lower parts of the flutes of a column are filled with a convex bead, they are said to be cabled. See ARCHITECTURE.

Fluting Machine, a machine for corrugating or crimping metals. It has a pair of rollers, each one having projections which enter the interdental spaces of the other. By turning the operating screw the bent bar, and with it the upper roller, can be adjusted up or down at will to regulate the distance between the two rollers.

Flux, a substance or mixture added to assist the fusion of minerals. In the large way, limestone, and fluor-spar are used as fluxes. In the smelting of iron great attention has to be paid to the fluxes, because on their character depends to some extent the complete separation of the metal. To accomplish this the flux must be such that it will combine with the earthy matter of the ore, and form a slag, which must neither be too refractory nor fusible. Hence if the ore abound in clay or sulphur, lime, or limestone, and possibly sand, must be added; if in quartz, lime and clay are requisite, otherwise the quartz is slagged by combining with part of the iron, which is thus lost. Frequently ores are so selected that the earthy matters present may flux each other, but this requires skill and experience. The fluxes used in pottery are very various, and are distinguished by different names; but they almost all consist of litharge or red-lead, with sand or boracic acid, sometimes singly, sometimes together. They are, therefore, essentially colorless glasses used as vehicles for infusible colors. See COPPER; IRON; etc.

Fluxion, fluk'shôn, (1) in medicine, an unnatural flow or determination of blood or other humor toward any organ; a catarrh. (2) In mathematics, a method of calculation resulting from the operation of fluents, or flowing numbers. Thus a mathematical line may be considered as produced by the fluxion or flowing of a point; a surface by the fluxion of a line, and a solid by the fluxion of a surface. A mathematical point in motion will really make a line; a revolving radius which is a line will make a circle which is a surface, and its revolution about its diameter will generate a sphere which is a solid. The same principle may be applied to purely numerical calculations, like the formulæ of algebra. This branch of the higher mathematics was invented by Newton in 1665. In 1676 he communicated his method to Oldenburg in a sentence with all the letters disarranged so that his correspondent could not possibly have put them in order. If he had succeeded in doing this the sentence would have been *Data æquatione quotcunque fluentes quantitates involvente fluxiones invenire et vice versa.* ["Given it makes no matter how many equations involving fluent quantities, fluxions are to be discovered, and the reverse is true" (that is, where fluxions occur the fluents are to be found).] Leibnitz received this letter in 1677, and in 1684 explained a discovery which he had made. It was that of the differential calculus, which was essentially the same as that of fluxions. What Newton called fluxions, Leibnitz called differences. An angry controversy subsequently arose between Newton and Leibnitz as to the priority of discovery, the Royal Society of London taking the part of the former, who was then its president, and the scientific men of Germany that of the latter, who was their countryman. Both appear to have made the discovery independently. In the slight differences of method which exist, the advantage lay with Leibnitz, and while the term fluxions is now scarcely ever used, that of differential calculus is in common use. The first elementary treatise on fluxions published in England was by John Harris in 1702. A description of the process by Newton himself followed in 1704, in his 'Quadrature of Curves.' See CALCULATION; MATHEMATICS.

Fly, an insect. See DIPTERA; FLIES; and the names of various groups and species of flies.

Fly-blister, a collection of blood-serum between the layers of the skin, caused by the application of some preparation of the Spanish fly. It is used to extract fluid from underlying tissues, and to cause desired changes in local circulation. Absorption from applications sometimes takes place, giving rise to the irritation and inflammation of the kidneys, bladder and genital organs which characterize the drug when taken internally.

Fly-casting, the art of throwing an artificial fly in angling. (For the various methods employed see ANGLING.) Aside from its use in actual fishing the art is employed by some in competitive contests, and "national tournaments" are held annually in both Great Britain and the United States, sustained by a federation of clubs devoted to the sport, in which the championship and prizes are competed for.

Fly River, a considerable stream in New Guinea (British) which has its source in the Victor Emanuel Mountains and empties into the Gulf of Papua. Its length is 150 miles. There is a delta at the mouth of Fly River in which lies the island of Kiwai.

Fly Sheet, a paper broadside or bill. Certain publications of this sort advocating changes in the English Wesleyan Methodist constitution and practice were published in 1847–8. Those who were suspected of having them issued were expelled in 1849, and taking the name of Methodist Reformers laid the foundation of a new denomination, which has, however, since been amalgamated with others, the designation of the collective body being the United Free Church Methodists.

Fly, Spanish. See BLISTER BEETLE.

Fly-up-the-Creek, a local name for the little green heron (*Ardea virescens*), a common bird throughout eastern North America. See HERON.

Flycatcher, popularly and broadly used, birds which catch insects in the air. More restrictedly, in ornithology, birds of the Old World insectivorous family *Muscicapidæ*, allied to the thrushes; but this is a group very difficult to limit or define. All these are small, active

FLYCATCHERS.

1. Spotted Flycatcher. 2. Pied Flycatcher. 3. White-collared and Red-breasted Flycatchers
4. Kingbird. 5 Bienteveo.

birds, with great activity in flight and skill in seizing their agile prey; and all have broad flattened beaks, at the base of which is a growth of long stiff rictal bristles. The feet are usually weak and the wings long and pointed. Four or five species are common summer visitors to Europe, including the familiar and typical spotted flycatcher (*Muscicapa grisola*) and the pied or blackcap (*M. atricapilla*). In all the hotter latitudes of the Old World the species are very numerous, and ornate, many being crested, or having, in the case of the males at least, very long tail-feathers, which are handled most gracefully. Such are the paradise flycatchers (genus *Tersiphone*) of India and eastward, the Japanese species of which is so commonly represented on painted or embroidered screens. The "fantail" (q.v.) is another species remarkable in its flight. Most of these flycatchers are birds of the woods, and are usually solitary and silent, feeding on little except insects, which are habitually caught upon the wing with an audible snap of the bill. Some of the smaller ones are sometimes called "fly-snappers" (q.v.). They nest in various situations, and many make highly beautiful receptacles for their variously decorated eggs.

None of the muscicapids is to be found in the New World, but America has a large family of flycatchers (the *Tyrannidæ*) just as suitably so-called as are the others, so far as habits are concerned; nor are they far removed in structure. This family contains some 400 species, mainly tropical, and chiefly of an olive-green, or black-and-gray complexion, often with ornamental touches of scarlet on the head or wings. The bill is rather stronger as a rule than in the Old World flycatchers, and often decidedly hooked, like that of vireos or shrikes. The wings are usually short, and the tail varies greatly, sometimes being beautifully prolonged, as in the scissor-tailed flycatcher of the western United States. The genus *Alectrurus* presents still more striking examples of very long and beautifully modified tail plumes. Good examples of this group are the king-birds, pipiris, pewees, vermilion flycatcher, and scissor-tail, elsewhere described. An excellent general account of these families will be found in Evans' 'Birds' (1900).

ERNEST INGERSOLL.

Flying Bridge. See BRIDGE; MOVABLE BRIDGES.

Flying Buttress, a contrivance by means of which the thrust of a vault or arch is carried across an open space to a buttress (q.v.). Nearly every instance of the use of the flying buttress is in connection with Gothic architecture, and some of the earliest forms are very curious and illustrate well the growth of the style. The "high vault" over the nave or choir should have a buttress on each side to resist its thrust, but to build one there would be to obstruct the aisle on either side, which it was important to leave open and free as a part of the great interior of the church. The buttress, therefore, was built outside of the aisle, where it took up the thrust of the aisle vault and was made much larger than necessary for that purpose so as to receive also the thrust of the high vault, which was transmitted to it by means of a sloping bar of stone carried on a separate arch or half-arch. This bar and half-arch taken together form the flying buttress. In large churches the flying buttress is sometimes double or two-fold, leaping over two aisles, or an aisle and a row of chapels; and again it is sometimes repeated in height, one flying buttress coming above another — these being sometimes an addition where a slight yielding was visible.

Flying Dragon, a flying lizard (q.v.) of the Oriental genus *Draco*.

Flying Dutchman, a phantom ship said to be seen in stormy weather off the Cape of Good Hope, and thought to forebode ill luck. One form of the legend has it that the ship is doomed never to enter a port on account of a murder committed on board; another, that the captain, a Dutchman, swore a profane oath that he would weather the Cape though he should beat there till the last day. He was taken at his word, and there he still beats, but never suceeds in rounding the point. He sometimes hails vessels and requests them to take letters home from him. The legend is supposed to have originated in the sight of some ship reflected from the clouds. It has been made the groundwork of one or two novels and of Wagner's opera 'Der Fliegende Holländer.'

Flying-fish, a fish able to leave the water when alarmed or pursued, and sustain itself for several seconds in the air. In tropical seas the flying-fish rise from the water in flocks, or, more properly, shoals, of many thousands at a time, when disturbed by the passing of a ship, or pursued by such foes as the bluefish and albicore. They spring from the crest of a wave, and, darting forward, plunge into another to wet the membrane of the fins, and in this manner continue their flights for several hundred yards, often pursued by marine birds in the element to which they are driven for protection against the tyrants of their own. The sole motive power is the propulsion obtained by the work of the tail in giving the rushing leap from the water; but the great pectorals act to some extent as parachutes. In all the species belonging to the genus *Exocœtus* (which is typical of the family *Exocœtidæ*, allied to the sauries), the pectoral fins are very much developed, and the superior lobe of the caudal fin shorter; the head and body are invested with large soft scales, and the body has a ridge or carina extending longitudinally along each flank, which gives it somewhat of an angular appearance. Head, when viewed from the front, triangular; eyes very large; air-bladder very large. Flying-fish are inhabitants of every temperate sea, though abounding in the vicinity of the equator. In length they rarely exceed 13 inches, and are commonly found about 8. The flesh is pleasant. Several species are described by naturalists, some of which have very long fleshy filaments depending from the lower jaw, the use of which is not known. The *Exocœtus volitans*, or common flying-fish of the Atlantic, is also known in Pacific waters; and the coast of California is visited by a large species, 18 inches long (*E. californicus*) called *volador* by the Spanish fishermen. About 65 species are contained in this and other genera, among which is *Fodiator*, with at least one common flying-fish (*F. acus*), distinguished by sharpness of its snout. Another sort of flying-fish is the gurnard or sea-robin (qq.v.).

Flying-fox, or **Fox-bat,** one of the great fruit-bats (q.v.) of the Oriental region; specifically the kalong (*Pteropus edulis*), which is regarded as good food by the people of Java and neighboring islands. It is the largest of known bats, measuring five feet in expanse of wings, has rusty red fur, woolly upon the neck, and a long pointed fox-like muzzle, short, triangular ears, and large eyes. These bats belong to a very large widespread genus, and have the general characteristics and habits of the fruit-bats (q.v.).

Flying Frog, a Malayan tree-dwelling frog of the genus *Rhacophorus*, which has large webbed feet with adhesive disks. Some 20 species are known in various parts of the tropics, one of which was believed by Wallace to sail down from trees in a long slanting flight; but there is no direct evidence of it as to any species. A full account of the varied habits of the genus will be found in Gadow's 'Amphibia and Reptiles' (1901).

Flying Gecko. See FLYING-LIZARD.

Flying Gurnard, or **Robin.** See FLYING-FISH.

Flying-lemur. See COLUGO.

Flying Lizards. Various lizards are provided with something more or less elaborate in the way of a parachute assisting them in springing from branch to branch, and perhaps in frightening off would-be enemies. Thus a Malayan gecko (*Ptychozoon homalocephalon*), about eight inches long, with membranous expansions along the sides of the neck, body, tail and limbs, which are supposed to enable it to make long, sliding leaps; but its habits are very little known. The term applies especially, however, to the East Indian "flying-dragons" or showy lizards of the genus *Draco*, which have loose folds of skin distensible by the erection of several movable ribs, and spread as a parachute. There are various species, harmless, pretty and tamable.

Flying Machine, a device for enabling man to navigate the air. The feat of flying has been often attempted; even among the ancients it was tried, and we are informed, succeeded to some slight extent. Friar Bacon affirms in his writings that this feat is not only possible, but he also informs us that he himself knew how to construct a machine in which a man, in a sitting position, might be able to transport himself through the air like one of the feathered tribe. The secret of Friar Bacon consisted of a very simple mechanical contrivance: It was a pair of globes made of hollow copper, exhausted of air, on which a chair could be supported, by which means a man could float in the atmosphere above the earth, and could buoy himself along. Another friar asserts the truth of this invention, or, at least, of one similar. Father Francisco Lana declares that a round vessel of plate-brass, 14 feet in diameter, weighing 3 ounces per square foot, will only weigh 1,848 ounces; whereas a quantity of common air of the same bulk will weigh 2,155 2-3 ounces; consequently he deduces the fact that the globe will not only be sustained in the air, but that it will be capable of supporting a weight of 373 2-3 ounces; and also that a globe of the same weight, but greater in capacity, would support a man. This, however, is a fallacy; for, from the fact of nature abhorring a vacuum, the globe would be crushed in by the superior force of the atmosphere. At many periods this subject has been taken up by philosophers, particularly in the reign of Charles II. For modern inventions under this heading see AËRIAL LOCOMOTION; AERODROME; AEROPLANE; BALLOONS; LANGLEY, S. P.; SANTOS-DUMONT.

Flying Mouse. See PHALANGER.

Flying Phalanger. See PHALANGER.

Flying-squid, a squid of the genus *Ommastrephes*, having two large lateral fins, which enable it to leap so high out of the water that sometimes these mollusks fall on ships' decks. See SQUID.

Flying Squirrel, a small squirrel with soft, dense fur; the skin on the sides capable of being drawn out by extending the legs, so as to form a "parachute," like that of the bat. There are various species native to America, Europe, and Asia, all falling within two genera, *Pteromys*, and *Sciuropterus*. In the latter genus are the European and American flying squirrels. The American species (*S. volucella*) is found from Maine to Florida and westward to the plains. It is entirely nocturnal in habits, and so closely resembles, in color, the bark of the dead trees wherein it makes its home that it is well-nigh invisible. Hence, less is known of it than of other squirrels. Yet when caught it proves to be a gentle, soft-eyed little creature easily tamed. All flying squirrels live in the woods, and gnaw into decayed tree-trunks, where such are obtainable, to make their nests. They feed on nuts, leaf-buds; and, sometimes, on birds' eggs, and even on small birds. Their sailing flight may extend as far as 60 feet, and they cover this distance with a rapid, graceful motion. Wherever found, flying squirrels seem to be fairly numerous, except in Alaska, where one species is found, but is very rare.

Flynt, Josiah. See WILLARD, JOSIAH FLYNT.

Flysnapper, a remarkable bird (*Phænopepla nitens*) of the southwestern United States, which belongs to the wax-wing family (*Ampelidæ*), but has the shy yet active movements of a flycatcher with a habit of jerking its tail. The male is shining bluish-black, with white wing-quills and vent, and a noble crest; his mate is gray, brown and white. It catches insects on the wing, by leaping from its perch and snapping at them noisily; but also eats mistletoe berries, etc. It makes a shallow nest in a low tree and lays eggs with dark dots about the small end. The term "flysnapper" is also given to some of the smaller flycatchers (q.v.).

Fly-wheel, a wheel employed in machinery, which by means of its great momentum renders equable and regular the motion which is generated by an irregular or intermittent force, or meets with an irregular or intermittent resistance. In order to effect this object its rim is made heavy, its circumference proportionately long, and it is hung on the revolving shaft of the machine it controls. Thus by its inertia it opposes any sudden acceleration of speed, and by its accumulated momentum it prevents sudden diminution of speed; acting in the latter case as a store of power to continue the movement when the motor temporarily flags, or in passing dead centres when the motor is inoperative.

Fo, the name given by the Chinese to Buddha. Originally, the name Buddha was expressed in the Chinese language with sufficient exactness by the term *Fô-thau,* pronounced *Fôudah;* but, as is usual in China with proper names, the last syllable was subsequently dropped. See BUDDHISM.

Foa, Eugénie, ė-jā-nē fōä, French author: b. Bordeaux 1708; d. 1853. Her maiden name was Fradis, and she was of Spanish-Jewish descent. Separated from her husband she supported herself by her pen, often writing under the name "MARIA FITZCLARENCE." Her tales for young children are delightfully clever. Notable among her works are: 'Les Mémoires d'un Polichinelle' (1839); 'Le Petit Robinson de Paris' (1840); and 'Le Vieux Paris' (1840).

Focus, a word introduced into science by Kepler in 1604. It literally means a hearth, round which all the members of a family gather, and takes the acquired meaning of the centre, into which certain activities are gathered. In optics it denotes the point at which divergent rays of light are brought to meet again, and from which they appear to proceed. The principal focus of a lens is the focus of rays falling upon the lens in a line parallel to its axis. The conjugate foci of a mirror or lens are two points so situated that the rays emitted from a light, or a luminous object, at either point, are reflected or refracted to the other. In photography the word is familiarly used of the image reflected on the screen of ground glass, which is said to be in focus when it is fixed at a true focal point, and so as to procure a focal or undistorted effect. It is also used of the lens, with regard to its distance from the screen of ground glass. The lens is in focus when it transmits to the screen an image without blurring or aberration. See LENS; LIGHT; MIRROR; OPTICS.

The term is employed in geometry in the description of the ellipse, which has two foci, of which it can be proved that the sum of the distances of any point of an ellipse from its foci is constant, and the difference of the distances of any point of a hyperbole from its foci is constant.

Fodder (A. S. *fódor,* cog. with Ger. *futter*), the food collected by man for the use of the domestic herbivorous quadrupeds. In English the term is commonly restricted to dried herbage, as hay and straw; but in other languages it is more comprehensive, and includes all the food of cattle, except what they gather for themselves in the field. The principal part of the food of the domestic herbivora is furnished by grasses, most of which are eaten by them when fresh and green. Besides the supplies which they receive of the surplus of corn cultivated for human food, they are also, to a considerable extent, dependent on the straw or dried herbage of the corn-plants for their winter provender; and that of many other grasses, cultivated on this account alone, is converted into hay for their use. Hay, being cut and rapidly dried while the plant is still full of sap, contains more nutritious matter than the ripened straw of the cereals. In the United States the best grasses are timothy, red top or Rhode Island bent, white top, orchard grass, and June grass or Kentucky blue grass. In California the best fodder grass is the alfalfa, of which three or even four crops a year are obtained.

Next to the grasses are ranked the *Leguminosæ,* affording food for cattle in their seeds — as beans, peas, lentils, lupines, etc. — and in their herbage, on account of which many of them are cultivated, as clover, lucerne, vetch, tares, sainfoin, etc. When consumed green, the produce of these crops is usually termed forage or green forage. (See SILAGE.) Some of them enter also largely into the composition of hay, being cut and dried with the grasses along with which they have been sown. Some of the *Cruciferæ* are cultivated to a considerable extent as forage-plants, cattle being fed on their green herbage, although they are not suitable for drying as fodder. Among these are kale and cabbage, rape, etc. In some parts of the world cattle are not unfrequently fed on the leaves of trees, as in the Himalayas, where the leaves of different species of Aralia, Grewia, elm, and oak are chiefly employed for this purpose, and are collected, dried, and stacked for winter fodder. In seasons of drought in India cattle are kept alive on the green leaves and pods of acacia and *Inga dulcis.* See ALFALFA; CLOVER; GRASSES; HAY; PASTURE; etc.

Fodder, Green. See SILAGE.

Fodientia, the aard-varks (q.v.); also EDENTATA.

Fœniculum. See FENNEL.

Foehn (fėn) **Wind,** a warm wind that blows from the Alps in some of the northern valleys of Switzerland. At one time the *fœhn* was supposed to be an air-current that had been warmed by passing over the Desert of Sahara. Now it is known that the *fœhn* is warm because it is a south wind which, robbed of its moisture by expansion and cooling in passing over the Alps is warmed by compression in descending through the increase of atmospheric pressure with decreased altitude. It corresponds to the Chinook wind of Montana, Washington, and British Columbia. See CHINOOK WIND.

Fœtus, fē'tus, **Development of,** the growth of the unborn child from the fourth month until its birth. The convolutions of the brain, distinguishable organs of sex, ossification, and muscular movement advance in the fifth month, during which nails and hair appear. During the sixth month the pubic bones ossify, eyelids and eyelashes form, fat develops under the skin. In the seventh month, the fat increases, the eyelids are open. During the eighth month the nails are fully developed, and the fœtus attains a weight of from 5 to 9 pounds. See also EMBRYO.

Fog, a very thick mist; small hollow vesicles of water suspended in the air, but so low as to be but a short distance from the earth in place of rising high above it and becoming so illuminated by the sun as to constitute clouds of varied hue. Fogs often arise when the air above warm, moist soil is colder than the soil itself. The hot vapors from the ground are then condensed by coming in contact with the colder air above, as the warm steam of a kettle is by the comparatively cold air of a room. But no fog arises till the cold air has absorbed vapor enough to bring it to the point of saturation. Fogs often hang over rivers. Their cause is the condensation by contact with the cold water, of the vapor in a hot and moist air current passing over the river. The "pea-soup" fogs of London life are produced by the carbon of the smoky atmosphere coloring the fog vesicles; a fog which is brown in London's business district is generally white a few miles off, and wanting altogether at the further extremities of the city. On hills and mountains of any size it is easy to rise above a fog, and see it like an ocean beneath one's feet.

Fog-signals, signals given by means of sound or light to warn vessels of danger during fogs. Various kinds of fog-signals are used, among which may be mentioned bells, drums, gongs, guns, compressed-air whistles, steam-whistles, and fog trumpets or horns, and latterly powerful electric flashlights. Gongs are not very powerful as signals, often failing to be heard at more than the distance of a quarter of a mile. Bells may be heard during fogs at a distance of from 1 to 3 miles. Guns have been heard as far as 10 miles, with a light breeze blowing across the sound. One of the most powerful signals is the siren fog-horn, the sound of which is produced by means of a disk perforated by radial slits made to rotate in front of a fixed disk exactly similar, while a long iron trumpet forms part of the apparatus. The disk is made to revolve rapidly, and when the slits are opposite each other openings are formed through which electricity, steam, or compressed air is forced. This causes a sound of very great power, which the trumpet collects and compresses, and which under favorable circumstances is heard from 20 to 30 miles out at sea. Fog-signals are also used on railways during foggy weather. They consist of cases filled with detonating powder, which are laid on the rails and exploded by the engine when it comes up to them. Bell-buoys, common to the coasts of the United States, are operated by the current, by the ebbing and flowing tide, by the swaying of the waves, by the wind, and by clockwork impelled by weight or spring. As to construction, they are adapted for anchorage on spits, sand-bars, or shoals. The use of electricity in fog-signals is well illustrated at Sandy Hook, N. J., where a powerful searchlight flashes every few moments in varying directions. In clear weather this flashlight can be observed a distance of 50 miles at sea. There are in the United States under government control nearly 10,000 fog-signals of all kinds, 3,000 of which are lighted. Eleven buoys are operated by electric light. Germany erected in 1903 a fast flashing light on the island of Helgoland in the North Sea. The system or principle employed is said to be entirely new. Not only that, but it was said to present absolutely insurmountable difficulties. The revolving light on Helgoland is not only the largest in the world, it is the most unique, for Germans claim that it never had a model.

They built upon the superiority of the German reflector, with its exactly parabolic ground-glass mirror or speculum, and the marvelous success of the Helgoland fast-flashing light has justified German effort, skill, and courage. In these lines, for a long time, France was in the lead. It looks as if she would have to guard her laurels. The reflector invented by Schuckert, with its parabolic mirror, is easily earning a place by the side of the world's very best work. It took a long time to get a hearing for the glass parabolic mirror in the lighthouse world. The bright fires — *feux éclairs* — of the system, based upon a combination of Fresnel lenses and totally reflecting ring prisms, which were built by the French with marvelous skill and accuracy, blocked the way to the new lights. About the middle of the nineties German experts were sent to France by the German imperial government for the express purpose of studying flashlights. The experts stayed long enough to find out all that was best in the French system, aided thereto by the kindness of the scientific men of the republic. Before their return they were convinced that by means of two or more reflectors, erected upon a reflector with Schuckert's glass parabolic mirror, results equal to those of France could be produced.

Experiments were made in Nuremberg. They went far beyond what the most sanguine had believed possible. The revolving reflector of the German apparatus was fully equal to the Frenchman's revolving light. As soon as the experts had demonstrated their point, work was begun on a light reflector or projector equal to the largest ever used. It was to represent 30,000,000 candlepower and to last no longer than one tenth of a second. The flashes must follow each other every five seconds. When the weather is favorable the beams go far beyond the central fires of light rays. On the first night that the new light was used, its peculiar, flashing beams were seen by people standing on the mole at Busum, a distance of 65 kilometres, or a trifle over 40 miles. The watchers in the lighthouse at Amrum, about the same distance, were able in unfavorable weather to see the same beams as they rapidly appeared and disappeared. It was noted that the otherwise bluish-white light of the electric arc appeared red. See BUOY; ELECTRIC LIGHTING; FOG; LIGHTHOUSE; MEGAPHONE; SIREN; TOPOPHONE.

Fogarassy, János, yän'ōsh fō'-gä-rŏsh-ī, Hungarian lawyer and philologist: b. Käsmark, in Austria-Hungary, 1801; d. 11 June 1878. He studied at Sáros-Pátak, and was graduated in law, became an advocate, and was appointed to an office in the government bureau of finance. His principal claims upon the memory of posterity are his legal works written in the Hungarian tongue. He also published a 'Hungarian Dictionary' (1836), and began, at the suggestion of the Hungarian Academy, a complete dictionary of the language in collaboration with G. Ezuczor, after whose death he finished the work single-handed. It was published in 1861, and for this achievement he was awarded a gold medal by the Academy.

Fogazzaro, Antonio, än-tō'nē-ō fō-gä-tsä'-rō, Italian poet: b. Vicenza, Italy, 1842. He first came into notice with 'Miranda,' a story in verse (1874), and added greatly to his reputation as a poet with 'Valsonda,' a volume of lyrics (1876). He was author of several novels which were received with marked favor, among them: 'Master Chicco's Fiasco' (1885); 'Daniel Cortis' (1887); 'The Poet's Mystery' (1888).

Fogelberg, Bengt Erland, bengt ĕr'länt fō'-gĕl-bĕrg, Swedish sculptor: b. Grotenburg 8 Aug. 1786; d. Trieste 22 Dec. 1854. He began his art studies in the Academy at Stockholm and in 1820 went to Rome, where he soon made a name. He was among the first to invest the mythologic figures of the North with the graces of the Grecian antique, and the influence of Thorwaldsen is plainly seen in his 'Odin and Thor' in the museum at Stockholm. He also vied with Thorwaldsen in such purely classic subjects as: 'The Dying Argus'; 'Venus'; 'Cupid and Psyche.' He executed two statues of Gustavus Adolphus, and, in collaboration with Byström, the series of colossal statues of the Swedish kings at Stockholm.

Foggia, fōd'jä, or **Capitanata,** cäp-ē-tän-ä'tä, Italy, a province on the Adriatic, between the provinces of Campobasso and Bari. It possesses rich pastures. Among its special products are wines, saffron, and fruits. The principal town is Foggia. Area, 2,688 square miles. Pop. (1901) 425,450.

Foggia, a city of southern Italy, capital of the province of the same name, in the centre of the great Apulian plain, 46 miles east by south of Campo Basso. It is well built, most of the houses being reconstructed since an earthquake which happened in 1732. It has large storehouses for keeping corn, and is the place where the flocks that feed on the great plain of Apulia are registered. Pop. (1901) 53,151.

Foglar, Ludwig, lood'-vĭg fō'glär, Austrian poet; b. Vienna 24 Dec. 1819; d. Kammer 15 Aug. 1889. Among his poems, mostly lyric, are: 'Cypresses' (1842); 'Sunbeams and Shadows' (1846); 'Clara von Vissegrad,' an epic (1847); 'Freedom's Breviary' (1848); 'Joyful and Sorrowful' (1867); 'Saint Velocipede' (1869), a satire (under the pseudonym "Lebrecht Flott").

Fo'go, Fuego, fwā'go, or **St. Philip,** (1) One of the Cape Verde islands, in the Atlantic Ocean, and the highest of the group, being 9,760 feet above sea-level, and presenting the appearance of one single mountain, though, on the sides, there are deep valleys; area, 170 square miles. Pop. estimated at 16,000. It has no rivers, and a scarcity of fresh water prevails, yet it is one of the most fertile islands of the archipelago, producing excellent maize and fruits. The chief town is Nossa Senhora da Luz. (2) Fogo, a port of entry and capital of Fogo Island, Newfoundland, at the southwest entrance to Notre Dame Bay, 122 miles northwest of St. John's, N. B. Pop. (1901) 1,118.

Fohi, fō'hē, the first Chinese emperor and legislator. He is said to have founded this kingdom 2,207 B.C. Nothing certain is known of his reign; but there are attributed to him the institution of marriage, the invention of fishing, hunting, music, and writing. He acknowledged and worshipped a supreme deity. He is supposed to be the Noah of the Bible.

Föhr, fėr, Germany, an island of Schleswig, in the North Sea; area 31 square miles. The town of Wyk is a fishing centre. The population numbers 4,200, mostly Frisians.

Foil. (1) A leaf or thin sheet of metal placed beneath transparent jewels to heighten their color and improve their brilliancy; also applied to those sheets of tin amalgam placed behind mirrors to make them reflect perfect images. They are made of copper, tin, and silvered copper, and are much used in imitations of precious stones. Colored foils are made by coating the white with any varnish of the required tint. The sheet lead which is used for the lining of tea-chests is a species of foil, and the Chinese purchase about 4,000 tons of lead annually from England for this purpose. (2) In architecture a small arc in the tracery of a window or panel. (3) In fencing. See Fencing.

Foix, Gaston, gas-täṅ fwä, Count de, and Viscount de Béarn, French military officer: b. 1331; d. 1391. Acquired the surname of Phœbus. He spent his life in war and the chase. His first service in arms was against the English in 1345. During the revolt known as la Jacquerie he contributed to the rescue of the Dauphin at Meaux. He wrote a book on the pleasures of the chase, of which several editions were published.

Foix, Gaston de, French soldier: b. 1489; d. Ravenna, Italy, 11 April 1512. He had the command of the army of Italy, and on account of the daring exploits was denominated the "Thunderbolt of Italy." After performing prodigies of valor he was killed at the battle of Ravenna.

Fokien. See Fu-Kien.

Fokshani, fōk-shä'nē, town in Rumania, population 23,800. Extensive vineyards are in the neighborhood and much wine is produced here. The town is well-known historically. It was destroyed by the Russians in 1789 and by the Turks in 1822.

Fold, in geology, a term used to denote an inclined position into which various disturbances may have moved rocks previously horizontal. Even very brittle rock may be thus folded, rather than broken, under a severe, steady pressure. Three kinds of fold are generally distinguished: (1) monocline, in which the rocks are inclined in one direction only; (2) anticline, in which they are bent up in the manner of an arch; and (3) syncline, in which the arch is bent downward instead of up. Folds are rarely symmetrical. See Dip; Fault.

Folding Machines. The folding of printed sheets for books or newspapers was performed by hand up to 1856, when Cyrus Chambers, Jr., of Philadelphia, invented a practical folding machine, which was manufactured by him and his brother Edwin, who within a few years produced a considerable line of folders of various sizes and capacities. The folding machine of C. S. Forsaith, of Manchester, N. H., designed for folding newspapers only, came out some years later. A good many Stonemetz folders were sold between 1880 and 1890. The leading folders on the American market to-day are the Dexter, the Chambers, and the Brown. The vital principle on which nearly all paper folders are based is the descent of a dull blade on the paper sheet at the point where the fold is to be made, the blade thrusting the paper between rotating rollers, which draw it in folded. The making of a second fold is accomplished in the same way, the paper being passed along by traveling tapes from one stage to another, up to three or four folds. The earlier machines were not positive in their register, that is, the fold was apt to vary slightly in position, but the modern machines are very accurate, and large 64-page sheets are commonly folded on the machines with entire satisfaction. The heavy coated paper introduced about 1890 to 1895 developed a tendency to buckle or crease slightly on the last fold of a large sheet, and the most recent folding machines have introduced devices to overcome this difficulty. The most conspicuous improvement of recent years has been the drop-roll, which has added materially to the speed of the machines. This was introduced by Dexter, and enabled the sheet to be fed sideways — that is, the shortest way. Registering by means of points, that slip into holes or slits in the sheet, is another feature of modern machines. The equipping of machines with pasters was accomplished early in the history of the folding machine, and this feature has been brought to a high degree of perfection. The paste is held in fountains and laid on the paper in strips as it passes by.

Folders are now made in so many styles that the mere enumeration of them requires considerable space. They may be either drop-roll or point-feed; there are quadruple 16s and double 32 folders, some of which insert one sheet within another; there are marginal folders for books and pamphlets and for jobbing work; also large single and combination periodical folders, rapid circular folders, plain circular folders, jobbing circular folders, and various so-called newspaper folders. Then there are special newspaper and periodical folders, combinded folding and wire-stitching machines, combined folding and feeding machines, and combined feeding, folding and wire-stitching machines.

The Dexter combined folding and wire-stitching machine was introduced in 1897, and it is continuous and strictly automatic. It takes the sheets from the platforms of the feeders, and folds, gathers, collates, covers, and wire-stitches, delivering completed copies without intermediate handling.

There are various other combinations and arrangements for special work, which, together with those above named, have greatly reduced the cost of binding books, pamphlets, and periodicals.

On fast web newspaper printing presses there is used a rotary type of folder, that was brought out by the Hoes, and controlled by them for many years, being probably their most valuable patent in connection with these presses. Three folding blades were mounted on a single cylinder, catching the paper three times in a single revolution, thus securing immense speed. The device is not accurate enough for book folders, but it made possible the enormous speeds obtained by the so-called lightning newspaper presses.

The job folding machines for doing odd work of varying sizes, have come into extensive use within a few years. They are small and comparatively simple machines capable of operating at high speed. See AMERICAN NEWSPAPERS.

Földvar, fėld'vär (ancient SUSSUINUM), a walled town of Hungary, on the slope and summit of a hill, on the right bank of the Danube, 49 miles south of Budapest. Pop. (1900) 12,364.

Folengo, Teofilo, tā-ō'fē-lō fō-len'gō (pseudonym «MERLINO COCCAJO»), Italian poet: b. near Mantua, Italy, 8 Nov. 1491; d. near Bassano, Italy, 9 Dec. 1554. He was the first to win fame as a writer of macaronic verses. His ‹Macaronic Work of Merlino Coccajo, Mantuan Poet› (1517–25) comprises the comico-heroic poems, ‹Baldus› and ‹Moscæa› (War of the Midges). His satire is mostly against monachism. He writes in cynic humor, but under his burlesque lies a vein of serious purpose. Under the pseudonym «LIMERNO PITOCCO» he wrote in Italian the epic satire ‹Orlandino› (1526), in ridicule of the story of ‹Roland›; then, partly in macaronic, partly in pure Italian, partly in pure Latin, ‹The Chaos of Three by One› (1527), in which he darkly recounts the events of his own life.

Foley, John Henry, Irish sculptor: b. Dublin 24 May 1818; d. Hampstead, England, 27 Aug. 1874. His ‹Ino and Bacchus› (1840) attracted much notice, and was followed by a succession of admirable classical and ideal works, including: ‹A Youth at a Stream›; ‹Caractacus›; and several excellent subjects from Shakespeare. The most noteworthy feature of his work, however, was his careful and artistic execution of his statues and busts, which incuded the Hampden and Selden figures in St. Stephen's Hall, Westminster; Goldsmith, Burke, and O'Connell, in Dublin; and the equestrian statues of Lord Hardinge and Sir James Outram, for India, which rank among the finest equestrian sculptures of modern times. The statue of the Prince Consort for the Albert Memorial is also Foley's work, and one of his latest works was a bronze statue of Stonewall Jackson for the State of South Carolina.

Folger, fōl'jėr, **Charles James,** American jurist: b. Nantucket, Mass., 16 April 1818; d. Geneva, N. Y., 4 Sept. 1884. He was graduated at Hobart College in 1836; and admitted to the bar in Albany, N. Y., in 1839. He became judge of the court of common pleas of Ontario County in 1843; was a member of the State senate in 1861–9; elected associate judge of the State court of appeals in 1871; succeeded to the chief justiceship of that court in 1880; and was secretary of the United States treasury in 1881–4. In November 1882 he was the Republican candidate for governor of New York, but was defeated.

Folger, Peter, American colonist and author: b. England 1617; d. Nantucket 1690. He emigrated from Norwich, Norfolk, to America and settled at Martha's Vineyard in 1635. He was grandfather of Benjamin Franklin, his daughter Abia having married Josiah Franklin and borne the illustrious statesman and philosopher among her 17 children. He was clerk of the courts in 1673 and possessed a literary sprightliness which descended to his grandson, as may be seen from a perusal of his ‹A Looking-glass of the Times, or the Former Spirit of New England Revived in this Generation› (1875).

Folgore, fōl'gō-rā, Italian poet. He flourished at the end of the 13th century, but the dates of his birth and death and the incidents of his life are unknown. He wrote a number of sonnets, all of which have been translated into English by Dante Rossetti and J. A. Symonds. Their poetic merit is far from contemptible, and they are particularly interesting from the vivid light which they throw on Italian society. Their prevailing tone is one of refined epicureanism, and their style is mainly remarkable for affluence of imagery. «Every line,» says Mr. Symonds, «presents a picture, and each picture has the charm of a miniature fancifully drawn and brightly colored on a missal marge.› See Rossetti, ‹Dante and His Circle› (1874); and Navone, ‹Le Rime di Folgore› (1880).

Folia'tion, a term restricted by Darwin, and subsequently by geologists, to the arrangement of the constituent portions of a rock in alternating and more or less parallel layers or folia of different mineralogical nature. It differs from cleavage (q.v.), which is applied to certain superinduced divisional planes that render a rock fissile; and from lamination, in which the planes of separation in a rock are the result of deposition in successive layers. If foliation postdate the formation of the rock, the structure is practically the same as that known as schistose. The folia are conspicuously lenticular, thickening and thinning out, and reappearing after an interval on the same or a different plane. These alternately lenticular folia are usually more or less closely welded or felted into each other, so that they are not readily separable; and they frequently present the appearance of being puckered or crumpled. The crystalline texture and the foliated character of the schists distinguish them at once from any ordinary bedded "fragmental rock." See SCHIST; SCHISTOSE.

Folio, (1) in printing: *a.* The running number of the pages of a book. The even folios are on the left-hand pages, the odd upon the right. The folios of prefatory matter are frequently in lower-case Roman numerals. *b.* A sheet of paper once folded. *c.* A book of the largest size, whose sheets are folded but once, four pages to the sheet; hence it is used generally for any large volume or work. (2) In bookkeeping, a page or opening in an account book. (3) In law, a certain number of words in legal documents. The number varies in the States; thus in some of them, as in England, in law documents, conveyances, deeds, etc., the folio is 72 words; in chancery and parliamentary proceedings 90 words. In New York and other States 100 words constitute a folio.

Fo'lium of Descartes, dā-kart, in mathematics, a curve such that the simultaneous increments of two lines drawn from the generating point of the curve to two fixed points, have always to each other a constant ratio. If the ratio is equal to -1, the oval becomes an ellipse; if it is equal to $+1$, it is an hyperbole.

Folk, Joseph Wingate, American lawyer and political leader: b. Brownsville, Tenn., 28 Oct. 1869. He was graduated at Vanderbilt University, studied law, and was admitted to the bar in 1890. Later he removed to Missouri, where he became prominent in his profession and in political life. As district attorney at Saint Louis, he was active in exposing political corruption and punishing the offenders. Owing to his efforts nearly 20 officers of corporations and city officials were convicted of bribe giving and taking; and afterwards similar corrupt practices in the State legislature were exposed. His fearlessness in attacking a long established evil and his success in accomplishing results won for him the confidence and admiration of the people of the State, and in 1904 he was nominated for governor by the Democratic Party in spite of the opposition of the party machine. He was elected governor of Missouri by a good majority, though the State went Republican in the national election at the same time.

Folk-lore, the science which embraces all that relates to ancient observances and customs, to the notions, beliefs, traditions, superstitions, and prejudices of the common people. Gomme's divisions are: (1) Traditional narratives: (a) folk-tales, (b) hero tales, (c) ballads and songs, (d) place legends; (2) traditional customs: (a) local customs, (b) festival customs, (c) ceremonial customs, (d) games; (3) superstitions and beliefs: (a) witchcraft, (b) astrology, (c) superstitious practices and fancies; (4) folk-speech: (a) popular sayings, (b) popular nomenclature, (c) proverbs, (d) jingle rhymes, riddles, etc.

Folk-lore had been observed and noted by countless writers of early days, but it was not till after the beginning of the 19th century that its value for the elucidation of the social history of mankind had become apparent to thinkers, and its systematic study been seriously begun. Meantime the reawakening to natural poetry, and to the beauty of free emotional expression in literature, which lay at the foundation of what it is usual to call romanticism, had already commenced even in the 18th century, and the publication of Percy's ‹Reliques of Ancient English Poetry› (1765) had given a powerful impulse to Scott and others in England, to Herder, and to Arnim and Brentano in Germany, who found a rich wealth of traditional poetry, the poetic value of which they fortunately had the eyes to see. But the study of folk-songs really began with Scott's ‹Minstrelsy of the Scottish Border› (1802-3). It was perhaps an advantage rather than a disadvantage that the first worker in this new field was but the folk-lorist unawares and mere great poet and romancer of genius that he was; for our folk-poetry would never have enriched and permanently influenced all later English literature but for its own intrinsic and genuine poetic quality, any more than our detached folk-lore facts would ever have risen above the dignity of the whimsical pastime of an idle hour but for their inherent though unsuspected faculty for throwing light backward on the history of human civilization. All, or nearly all, the facts of comparative mythology are to be found in folk-belief in solution; a great many facts of folk-belief are to be found in comparative mythology crystallized. The facts are essentially the same in both cases, but the one study deals with them at one, the other at another stage.

First in importance of the collections of material is still the earliest, the ‹Children and House Tales› (1812-14) of the brothers Grimm (q.v.). Grimm's ‹German Mythology› (1835) is still unequaled in the range of its erudition and in the systematic thoroughness with which the mythology and superstitions of the ancient Teutons are traced back to the dawn of direct evidence and downward in decay and diminution to the popular tales, traditions, and phrases in which they still unconsciously survive. These two works of Grimm created a school, whose abundant labors later folk-lorists have entered into, while they have enlarged the horizon of the science, because the stamp of soundness and sufficiency so far as it goes is impressed in all the work of Grimm and his successors, of whom, in Germany, the most eminent were Kuhn, Mannhardt, J. W. Wolf, and W. Schwartz. To the English-speaking world Max Müller's essays revealed a new world of undreamt-of affinities, and the combined charm of their literary grace, wide learning, and rare powers of exposition converted every reader to a theory which, as has been seen, is only now being displaced by another with a sounder basis of real philosophy and facts. Since then the study of folk-lore has become fashionable, indeed almost an article of patriotism, and societies have been formed in most countries to further its study. Of these the most important is still the Folk-lore Society of England, established in 1878, with its official organ, the 'Folk-lore Journal.' The American Folk-lore Society was instituted at Cambridge, Mass., early in 1888: (1) For the collection of the fast-vanishing remains of folk-lore in America, namely: (a) Relics of old English folk-lore (ballads, tales, superstitions, dialect, etc.); (b) lore of negroes in the Southern States of the Union; (c) lore of the Indian tribes of North America (myths, tales, etc.); (d) lore of French Canada, Mexico, etc. (2) For the study of the general subject, and publication of the results of special studies in this department. Already its journal has amply justified its existence by a series of articles of striking originality and value.

Folk-lore, though it takes cognizance of many apparently trivial matters, is of great importance in the science of comparative mythology, and helps to throw much light on the relationships between races, and on the origin and development of religious beliefs and ceremonies. It is, therefore, of great assistance to the ethnologist, the sociologist, and the historian, as well as to the student of comparative mythology and of the science of religion. It has attracted much attention in recent times. See ASTROLOGY; FABLES; FAIRY TALES; LEGENDS; MYTHOLOGY; SUPERSTITION; WITCHCRAFT.

Bibliography. — Aubrey, 'Miscellanies' (1696); Browne, 'Pseudodoxia Epidemica' (1646); Brand, 'Popular Antiquities'; Chambers, 'Book of Days'; Hone, 'Everyday Book'; Hone, 'Year Book'; Lang, 'Custom and Myth'; 'English Folk-lore Journal'; 'American Folklore Journal.'

Folk-music. The music of a nation is generally based on folk-music, or the folk-tunes that are handed down from generation to generation along with folk-lore. Hungarian folk-music has provided material not only for native composers but for the Germans. Haydn, Liszt, and Schubert utilized the melodies of the Magyars and the Gypsies. Brahms and others did the same thing in Russia. Beethoven went to Scotland and Ireland for melodies and Puccini traveled as far as Japan for one of his operas. Of all European countries Germany and Ireland have probably the greatest variety of folk-songs. (See FOLK-LORE; MUSIC.) Consult: Engel, 'Study of National Music' (1886); Tinck, 'Songs and Song Writers' (1900); Parry, 'Evolution of the Art of Music' (1896).

Folk-psychology, an ethnological study of the psychology of races and people, differing from folk-lore, which studies survivals. Among modern students of this science are Baldwin, Wundt, Lombroso, Lazarus, Steinthal and Felix Adler. Folk-psychology considers the habitat and food conditions of a people, its somatology, sex, technology, æsthetics, jurisprudence and pathology. Nearly all the books written upon this subject have been published only in German. See ETHNOLOGY.

Folk-right, the native laws and customs in Early English history as distinguished from the rules and observances introduced by William the Conquerer and his followers. See ENGLAND.

Folkestone, or **Folkstone**, fōk'stōn, a fortified seaport town of England, in Kent County, 62 miles southeast of London, and 7 west of Dover. It possesses a spacious harbor and fine pier whence the tidal steamers sail twice a day to Boulogne on the French coast. It was the birthplace of William Harvey (b. 1578), the discoverer of the circulation of the blood. Pop. (1901) 30,694.

Folk'land, or **Folcland**, fok'land, the land of the people, that portion of Anglo-Saxon England which was retained on behalf of the community. It might be occupied in common or possessed in severalty, but could not become allodial estate or absolute private property except with the consent of the Witan or highest council in the land. From time to time large grants were made both to individuals and to communities; and land thus cut off from folcland was called bocland or "book-land." Ultimately the king practically acquired the disposal of it, and the remnant of folkland became crown lands.

Folkmar, Daniel, American anthropologist: b. Roxbury, Wis., 28 Oct. 1861. He was graduated at the Western College of Iowa in 1884 and continued his studies at Paris and Berlin. He subsequently taught in several western institutions of learning (1895–1900) and was professor of anthropology in the Université Nouvelle of Brussels 1898–1901. Among his many writings are: 'L'Anthropologie Scientifique' (1899); and 'Leçons d'Anthropologie Philosophique' (1900).

Folkmoot, fōk'moot', or **Folcmote**, in Anglo-Saxon England, an assembly of the people to consult respecting public affairs.

Folks, fōks, **Homer**, American sociologist: b. Hanover, Mich., 18 Feb. 1867. He was graduated from Albion College (Mich.), in 1889, from Harvard in 1890, was superintendent of the Pennsylvania Children's Aid Society 1890–3, and in 1893 became secretary of the New York State Charities Aid Association. In 1900 he assisted the United States military government of Cuba in reorganizing the public charities of the island. He has written a 'History of the Care of Destitute, Neglected and Delinquent Children in the United States during the 19th Century.'

Fol'len, August, ow'goost, later **Adolf Ludwig**, German poet: b. Giessen, Germany, 21 Jan. 1794; d. Bern, Switzerland, 26 Dec. 1855. He became extremely popular as the author of 'Sons of Fatherland,' a patriotic hymn; 'Malegys and Vivian' (1829), a romance of chivalry; and numerous translations and poetic appeals to the instinct for liberty. He was a brother of Charles T. C. Follen (q.v.).

Follen, Charles Theodore Christian, American professor and Unitarian clergyman: b. Romrod, Hesse-Darmstadt, 4 Sept. 1786; d. 13 Jan. 1840, in the burning of the steamer Lexington, on Long Island Sound. He was educated at

Giessen, and became professor of Latin and history at Coire, Switzerland. His liberalism in politics and theology caused him to be driven from that town, and he was afterward forced to leave Basel, where he lectured on law and metaphysics, for the same reason. He finally took refuge in the United States and for five years (1830–5) was successful as professor of German at Harvard. He then took charge of the First Unitarian Church of New York, a position which he retained for a year (1836–7). He removed to East Lexington, Mass., in 1839.

Follen, Eliza Lee Cabot, American author: b. Boston, Mass., 15 Aug. 1787; d. Brookline, Mass., 26 Jan. 1860. She was married to Charles T. C. Follen (q.v.) in 1828. She published: 'Poems' (1839); 'Twilight Stories' (1858); 'Home Dramas' (1859), etc.

Folly Island, a small island off the coast of South Carolina, in Charleston harbor. It is separated from the mainland by Folly Island channel. It was the scene of several engagements during the Civil War.

Folsom, Charles, American scholar: b. Exeter, N. H., 1794; d. 1872. He was graduated from Harvard in 1813, was in the navy as chaplain and midshipmen's instructor in mathematics, was tutor at Harvard in 1821–3, and librarian in 1823–6. In 1824 he was associated with William Cullen Bryant in the editorship of the 'United States Literary Gazette.' As a member of the printing firm of Folsom, Wells & Thurston he long prepared for the press the classical works used at Harvard. Publications: An edition of Cicero's selected orations (1811), and an edition of selections from Livy (1829)

Folsom, Charles Follen, American physician: b. Haverhill, Mass., 3 April 1842. He was graduated from Harvard in 1862, was in the Southern States in connection with the Freedmen's Bureau from 1862 to 1865, and after study in the Harvard Medical School practised medicine in Boston from 1870. In 1877–82 he was lecturer in hygiene at Harvard, and in 1879–88 lecturer in and assistant professor of mental diseases. Among his writings is a volume on 'Mental Diseases.'

Folsom, George, American antiquary: b. Kennebunk, Maine, 23 May 1802; d. Rome, Italy, 27 March 1869. He was graduated 1822, studied law, and removing to New York in 1837 became librarian of the New York Historical Society. He was a member of the New York State senate 1844–8, and was appointed *chargé d'affaires* at the court of the Netherlands 1850–4, and was for some years president of the American Ethnological Society. Among his publications are: 'History of Saco and Biddeford, Maine' (1830); edition of the 'Collections of the New York Historical Society' (1841), translation of 'Despatches of Hernando Cortes'; 'Political Condition of Mexico' (1843); 'Documents Relating to the Early History of Maine' (1858).

Folsom, Joseph L., American soldier: b. Meredith, N. H., 19 May 1817; d. San José, Cal., 19 July 1855. He was educated at West Point, and served four years in Florida against the Indians (1840–4), and in California in the Mexican war. He communicated officially to the government the discovery of gold in that State: and Folsom City on the American River, near the earliest found gold deposits, is named after him, as one who became identified with the development of the State and especially of San Francisco, where he was a large property owner.

Folsom, Nathaniel, American soldier and statesman: b. Exeter, N. H., 1726; d. there 26 May 1790. He was in command of a company at Fort Edward 1755, and of a regiment later, being brigadier-general of the New Hampshire Contingent in the siege of Boston, and was elected to the Continental Congress 1774–5 and 1777–80.

Foltz, Philipp von, fē'lēp fōn fōlts, German painter: b. Bingen 11 May 1805; d. Munich 5 Aug. 1877. At Munich he was a pupil of Cornelius, whom he assisted in the decoration of the Glyptothek and the arcades in the Hofgarten. He was later a professor in the Academy, and in 1865–70 director of the Centr l Gallery. His historical paintings are minute and faithful in detail and skilfully designed in their pictorial arrangement, but they fail of proper effect from stilted drawing and dryness of color. The Cologne Museum possesses his 'Minstrel's Curse' (after Uhland's ballad); the Maximilianeum, Munich, his 'Humiliation of the Emperor Frederick I. before Duke Henry the Lion,' and 'Pericles attacked by Cleon and his Followers.'

Fol'well, William Watts, American educator: b. Romulus, Seneca County, N. Y., 14 Feb. 1833. He was graduated at Hobart College, later becoming assistant professor of mathematics there; was appointed professor of mathematics at Kenyon College, Ohio, 1869, becoming president of the University of Minnesota the same year, later, professor of political economy there. Author of 'Public Instruction in Minnesota' (1875); 'Lectures on Political Economy.'

Fond du Lac, fŏn'do-lăk, a city and county-seat of Fond du Lac County, Wis., on Winnebago Lake, at the mouth of Fond du Lac River, and on the Chicago, M. & St. P., the Chicago & N. W., and the Wisconsin C. R.R.'s: about 60 miles northwest of Milwaukee. Fond du Lac was first settled in 1836 by Germans; became a village 1 March 1847, and a city in April 1852.

Industries, etc.— Fond du Lac has important manufactures and is noted for its dairy and agricultural products. The chief industries, besides agriculture, are lumber, grain, flour, leather, paper, machinery, refrigerators, sash and doors, shoes, wagons, furniture, shirts, etc. The city has four banks, with a combined capital of $500,000, and an annual business of $15,000,000.

Buildings, Churches, etc.— The principal buildings are the Carnegie Public Library, Elks' Club House, Saint Mary's Springs Sanitarium, Saint Agnes' Hospital, and Henry Boyle Roman Catholic Home for the Aged. The city has also an excellent public school system (10 buildings), a parochial school and a cathedral school.

Government.— The city is governed by a mayor, elected annually, and a council of 32 members elected biennially, half each year. Pop. (1900) 15,110; (1903 est.) 16,037.

E. M. Jenison,
Editor 'Daily Commonwealth.'

Fon'da, N. Y., a town and county-seat in Montgomery County, on the New York C. & H. R. R.R. It is a thriving centre of a large agricultural district, has one bank and several newspapers. Pop. (1900) 1,190.

Fondi, fōn'dē, the ancient FUNDI, a town of Italy, Naples, in the province Terra di Lavoro, near a lake to which it gives name. It is a bishop's see, and contains a cathedral. The Lake of Fondi (ancient *Lacus Fundanus* or *Amyclanus*) lies between the road and the sea; it sends forth noxious exhalations. Pop. (1901) 9,930.

Fonseca, Antonio Manuel da, äṅ-tō'nē-o mä-noo-äl' dä fōṅ-sā'kä, Portuguese artist: b. Lisbon 1796; d. 1893. He studied in the Academy at Lisbon, became a professor there, was in 1839 appointed court-painter and in 1862 was elected corresponding member of the Academy of Fine Arts at Paris. Several of his pictures, which are chiefly of a historical character, were exhibited in the Paris Exposition of 1855.

Fonseca, Juan Rodriguez, hoo-än' rō-drē'geth fōn-sā'kä, Spanish ecclesiastic and statesman: b. Toro, near Seville, 1451; d. Burgos 4 Nov. 1524. He passed through many grades of preferment from the archidiaconate of Seville, to the archbishopric of Burgos, where he became *limosiuero* or private chaplain to the king and queen. In 1493 Ferdinand and Isabella appointed him to superintend the preparations for the second voyage of Columbus and practically to administer the affairs of the New World. He became first president of the Council of the Indies (q.v.), organized in 1511. His conduct in the discharge of this office has been stigmatized by modern historians, and he has been charged with shortsightedness, if not with malignity in his treatment of Columbus, Cortes and Las Casas.

Fonseca, Manuel Deodoro da, mä-noo-äl' dā-ō'dō'-ro dä fōṅ-sā'kä, Brazilian soldier and politician: b. province of Alagoas 5 Aug. 1827; d. Rio de Janeiro 23 Aug. 1892. He was educated as a soldier and graduated with the rank of sub-lieutenant of artillery in 1849. He saw active service in the Paraguayan war (1868–70), and attained the rank of major-general. In 1887, although a conservative and personally attached to the Emperor Dom Pedro II., he and others felt bound to protest against the acts of the government. They were punished for insubordination, revolted, and proclaimed a republic, which was recognized by the United States and later by the powers of Europe. Dom Pedro was banished and Fonseca was elected president of the government 24 Feb. 1891. In November of the same year he was accused of arbitrary acts and compelled to resign. He was succeeded by the vice-president, Peisoto.

Fonseca Lima e Silva, Manuel da, mä-noo-äl' dä fōṅ-sā'kä lē'mä ā sēl'vä, Brazilian soldier: b. Rio Janeiro 1793; d. 1862. He entered the Portuguese army in Brazil, and was apointed lieutenant-colonel in the struggle which subsequently took place for the independence of the country. Under the new régime the Emperor Pedro I. chose him as lord chamberlain. When Pedro abdicated (1831) Fonseca sided with the Liberals and rose to high rank in the government, being minister of war (1831), minister of the interior (1836), and in 1851 he was apointed general and commander-in-chief of the army.

Fonse'ca, fōn-sā'kä, or **Conchagüa,** cōn-chä'gwa, a bay on the Pacific coast of Central America, the proposed terminus of a projected interoceanic railway through Honduras. It is one of the largest bays in the South Pacific and affords one of the finest harbors in the world.

Font. (1) In church architecture, the vessel which contains the water for baptism. It is frequently sculptured in stone or marble, with richly decorative designs. The form of font with which we are now familiar seems to have been introduced in mediæval churches. In the early Latin Church, from the time of Constantine, baptism was administered in baptisteries, which were buildings separate from but adjoining the church. (See BAPTISTERY.) (2) An assortment of any particular kind or size of type used in printing, each font containing a proportionate number of letters, figures, spaces and punctuation marks. See TYPE.

Fontaine, Pierre François Léonard, pēār fräṅ-swä lā-o-nar fôṅ-tān, French architect and author: b. Pontoise, France, 20 Sept. 1762; d. Paris 10 Oct. 1853. He took the second grand prize of Rome 1785, going to Italy in 1786, and there connecting himself with Percier (q.v.), who, as director of the decorations of the Opera, Paris, called him to his aid, a partnership then being formed which lasted till 1814, when Percier retired. They constructed a beautiful stairway in the Louvre; the Arc du Triomph du Carrousel; the arcades of the Rue de Rivoli as far as the Rue de l'Echelle. He retained the favor of Louis XVIII. and Louis Philippe, constructing the Galerie d'Orleans at the Palais-Royal, the Chapelle Expiatoire, the Chapelle Ferdinand, repairs of the Louvre and the Tuileries, and the hospital at Pontoise. He wrote: 'L'Histoire du Palais-Royal'; and, in collaboration with Percier, 'Palais, maisons et autres edifices de Rome moderne' (1802); 'Choix des plus celebres maisons de plaisance de Rome et ses environs' (1809–13); 'Descriptions de cerémonies et de fetes' (1807–10); 'Recueil des decorations intérieures' (1812–17); 'Residences des souverains' (1833).

Fontainebleau, fôṅ-tān-blō, a town of France, in the department of Seine-et-Marne, and in the midst of the forest of same name, about 2 miles from the left bank of the Seine, and 37 miles east of Paris. It is well built, partly of stone and partly of brick, with spacious and regular streets; is the seat of a court of first resort, and several public offices; contains fine barracks, a communal college, school of design, public library of 28,000 volumes, public baths, and several hospitals; and has manufactures of calico, porcelain, and stoneware; quarries of sandstone, extensively used in paving the streets of Paris and the roads of the surrounding districts; and a trade in wine, fruit, preserves, cattle, etc. Pop. (1901) 14,160. The castle or palace of Fontainebleau, from which the town derives its chief importance, is one of the most magnificent in France. Many of its sovereigns have made it their favorite residence, and vied with each other in lavishing upon it all the embellishments that art could furnish, without any limitation as to expense. Henri IV., Louis XIV., Napoleon I., Louis Philippe, and Napoleon III. all expended large sums upon it. It is now a summer residence of the president of the republic.

Fontainebleau, School of, a group of artists assembled at Fontainebleau in France by Francis I., where they were employed in decorating the palace. There were two branches, Flemish and Italian; the influence of the latter, led by Rosso dei Rossi (1495–1541), eventually dominated French art (q.v.). See FRANCE: *Painting and Sculpture.*

Fontana, Carlo, kar'lō fōn-tä'nä, Italian architect: b. Brusciato, Italy, 1634; d. Rome 1714. He was a pupil of Bernini. While still very young he executed important commissions, including the Grimazzi and Bolognetti palaces, the monument of Queen Christina of Sweden in St. Peter's, and the fountains of St. Peter, and Santa Maria in Trastavere. He also built the cathedral at Fulda. Among his published works are: 'Il Tempio Vaticano e sua origine, con gli edifici piu cospicui antichi e moderni' (1694); 'Ultissimo Trattato delle acque correnti' (1697); 'L'Anfiteatro Flavio' (1725).

Fontana, Domenico, dō-men-ē'kō, Italian architect: b. Mili, Italy, 1543; d. Naples 1607. Cardinal Montalto (afterward Pope Sixtus V.) engaged him to construct a chapel in the Church of Sta. Maria-Maggiore, and a palace in the garden of the same church. But the pecuniary resources of the cardinal failed and the undertaking would have been interrupted had not Fontana himself supplied the means for continuing the work. Sixtus V. wished to remove the great obelisk now in front of St. Peter's Church, which was then nearly buried under the rubbish, to the middle of the square. Fontana happily executed this gigantic operation in 1586. Among other buildings erected by Fontana by the command of Sixtus V., the library of the Vatican and the aqueduct (*acqua felice*), deserve particular mention. Having been accused of converting to his private use the money received for public purposes, he was deprived of his office by the Pope, but immediately received the offer of the post of architect and chief engineer of the king of the Two Sicilies, and in 1592 went to Naples. He there constructed several canals to prevent inundations, a new road along the bay, and the royal palace in the capital.

Fontana, Felice, fā-lē'chā, Italian physiologist: b. Pomarolo, in the Italian Tyrol, 1730; d. 1805. He was appointed professor of natural philosophy in the University of Pisa, and while retaining this position he formed the museum at Florence which contains an immense number of anatomical preparations in colored wax, which exhibit all parts of the human body in the minutest detail, and in all imaginable positions. They are executed with the greatest skill, and were made by different artists under the direction of Fontana. Fontana wrote several works on scientific subjects, some of which have been translated into German and French. He also made discoveries relative to the application of carbonic acid, and different sorts of gas. He was buried in the Church of Santa Croce by the side of Galileo and Viviani.

Fontane, Marius, mä-rios fôṅ-täṅ, French writer and administrator: b. Marseilles 4 Sept. 1838. He met Ferdinand de Lesseps in the Orient and became his secretary, shortly afterward being appointed chief of exploitation and secretary-general of the Suez Canal Company and later administrator and member of the Committee of Direction of the Panama Canal Company. He was implicated with the other officers in the downfall of that company, was condemned in 1893 to two years' imprisonment, but this verdict was set aside on appeal, and after another trial he was acquitted. Among his works are: 'Les Marchands de Femmes' (1863); 'Confidences de la vingtieme annee' (1863); 'Selim l'egorgeure' (1865); 'Zara la rebelle' (1866); 'La Guerre d'Amerique' (1866); 'Le Canal maritime de Suez' (1869); 'Essais de poesie vidique' (1876); 'L'Histoire universelle' (Vol. I. 1881, Vol. X. 1899).

Fontane, Theodor, tā'ō-dōr fōn-tä'nĕ, German author: b. Neuruppin, Prussia, 30 Dec. 1819; d. Berlin 21 Sept. 1898. Among his writings are three volumes on England, one 'A Summer in London' (1854); 'The Sleswick-Holstein War of 1864' (1866); 'The War with France' (1876); and other war histories. His first volume of lyrics, 'Men and Heroes,' was published in 1850; his collected 'Ballads' in 1892. He wrote stories of North German life, as 'Count Petöfy'; 'Under the Pear-Tree' (1885); 'Mrs. Jenny Treibel' (1892).

Fontanes, Louis, loo-ē fôṅ-tän, MARQUIS DE, French writer: b. Niort, Poitou, 6 March 1757; d. Paris 17 March 1821. He went in 1777 to Paris, where he acquired a reputation by his poems: 'Le Cri de mon Cœur' (1778); 'Le Verger' (1788); 'L'Essai sur l'Astronomie' (1789); and 'L'Epitre sur l'Edit en Faveur des Non-Catholiques' (1789). He also wrote a metrical translation of Pope's 'Essay on Man' (1783). In 1802 he was made a member, and in 1804 president, of the legislative body. His admiration of Napoleon was great; and his oratorical talents were often employed in eulogizing the emperor's acts. In 1810 he entered the senate, and, passing on the fall of Napoleon into the service of the Bourbons, was raised to the peerage by Louis XVIII. His writings, prose and poetic, which are regarded as models of elegance and correctness, were edited by Sainte-Beuve in 2 volumes in 1837, with a critical and biographical memoir.

Fontarabia. See FUENTERRABIA.

Fontenelle, Bernard le Bovier de, bär när lė bō-vyā dė fôṅt-nel, French poet and miscellaneous writer: b. Rouen 11 Feb. 1657; d. Paris 9 Jan. 1757. Although he lived to the age of nearly 100 years, and retained, till his death a remarkable degree of activity, he came into the world so weak that it was not thought possible that he could survive. In 1674 he went to Paris, and soon became known by his poetical effusions and learned works. Before the age of 20 he had assisted in the composition of the operas of 'Psyche' and 'Bellerophon,' which appeared under the name of his uncle, Thomas Corneille (q.v.). In 1683 appeared his 'Dialogues of the Dead,' which were favorably received, although his continual straining after wit and novelty deprives them of the charm of natural ease. His 'Entretiens sur la Pluralité des Mondes' (1686) was the first book in which astronomical subjects were discussed with taste and wit.

Fontenoy, fôṅt-nwä, **Battle of,** one of the most famous battles in the war of the Austrian succession. It was fought at a small village of the same name, in western Belgium. Here 11

May 1745, the French under Marshal Saxe defeated the Allies under the Duke of Cumberland, with very heavy loss on both sides.

Fontevrault, fônt-vrō, a commune of France, in the department of Maine-et-Loire, with 3,581 inhabitants, situated in the middle of a forest occupying a valley in which flows a perennial fountain, 10 miles southeast of Saumur. This valley is celebrated as the site of the rich Benedictine abbey founded by Robert d'Arbrissel in 1099.

Fontevrault, Order of, a branch of the Benedictine order of monks; so named from the place in France where the first monastery of the sect was erected. The order was started in the 12th century by Robert of Abrissel, who brought monks and nuns under one roof, and placed them under the government of a female, because Jesus placed John in subjection to the Virgin Mary, saying: "Woman, behold thy son" (John xix. 26). The founder of the monastery was suspected of immorality, a charge which his followers strenuously denied. In 1106 the order received the sanction of Pope Pascal II.; in 1113 it was exempted from episcopal jurisdiction. In 1177 some monks connected with it came over to England by invitation of Henry II. It was remodeled in 1507 by the Abbess Renée of Bourbon.

Fonvielle, Wilfried de, wēl-frēd dė fôṅ-vyĕl, French scientific writer: b. Paris 21 July 1824. He aimed to popularize scientific truths by his writings, of which the best known are: 'Fossil Man' (1865); 'Balloons in the Siege of Paris' (1871); 'The Physics of Miracles' (1872); 'The Conquest of the North Pole' (1877); 'The Wonders of the Invisible World' (5th ed. 1880); 'Thunders and Lightnings' (4th ed. 1885); 'History of the Moon' (1885); 'Hypnotizers' (1887); 'The South Pole' (1888); 'Famous Vessels' (1890); besides one or two minor historical works.

Fonviz'in, Denis Ivanovich, Russian author: b. Moscow, Russia, 14 April 1745; d. St. Petersburg 12 Dec. 1792. His fame as the Molière of his country arises from two comedies: 'The Brigadier' (1766), and 'The Minor' (or 'Mother's Favorite Son') (1782). He wrote also a burlesque, 'Court Grammar,' and mock correspondence of a facetious sort.

Foochow, foo-chow', or **Fu-Chau,** town in China, capital of the province of Fu-Kien, in a plain surrounded by an amphitheatre of hills, on the left bank of the Min, 125 miles northeast of Amoy. It consists of the town proper, surrounded by walls, and of extensive suburbs, which, stretching along both sides of the river, communicate by a stone bridge. The walls, 30 feet high and 12 feet wide at top, are overgrown with grass, and the gates, seven in number, are overlooked by high towers. The streets are extremely dirty, and the lines of shops, crowded with goods or with workmen in the act of making them, make the whole place look like one vast series of market-stalls. The principal edifices are the Ching-hwang Miau, and several other temples. Foochow is one of the five ports thrown open by the Treaty of 1843. The trade is very extensive, but the navigation of the river from the sea to the harbor is difficult. Principal exports — timber, bamboo, fruits, tobacco, potash, paper, and especially for the foreign trade — tea. In 1900 the exports amounted to $3,889,490. The imports in 1900 were of the total value of $4,088,560. Pop. (1900) 650,000.

Food, any substance which, taken into the body, is capable of sustaining or nourishing or which assists in sustaining or nourishing the living being. Foods may be classed under three heads, gaseous, liquid, and solid, the first two consisting of the air we breathe — the oxygen of which is so essential to life — and the water we drink. Milk, tea, coffee, cocoa, etc., are popularly called liquid foods, but each of these is simply water in which various solid substances are dissolved, or held in suspension. The solid foods are of three kinds — namely: nitrogenous, non-nitrogenous, and mineral. Nitrogen compounds, or flesh formers, are essentially composed of carbon, hydrogen, oxygen, and nitrogen. They possess the only ingredients capable of building up and repairing the nitrogenous tissues of the body, but they also furnish a limited supply of heat, especially when heat-giving compounds are deficient in the body. Nitrogenous compounds are found both in the animal and vegetable kingdoms under the forms of albumen, fibrin, casein, gelatine, and chondrin. Non-nitrogenous compounds, or heat givers, sometimes called carbonaceous compounds, are composed of carbon, hydrogen, and oxygen. They serve to keep up the heat of the body, and so produce energy or force; but they contribute also to the repair and growth of the body. The chief heat givers are starch, sugar, and fat. None of these substances will of itself sustain life. The mineral foods are the salts of soda and potash, the phosphates of lime and magnesia, iron, etc. Common salt is the only mineral substance purposely added to food, the other mineral substances being found in nearly all parts of plants and animals used as food. Milk is a natural model food, as it furnishes all the nourishment required, and in due proportion. Oatmeal may also be called a model food, as it contains one part flesh formers and 5½ parts of heat givers. In fine wheaten flour the proportion is as one to eight, a part of the flesh-forming body having been removed in its preparation. The adulteration of any article of food reduces one or both of its essential constituents. The National Pure Food Law, which went into effect in the United States 1 Aug. 1900, was aimed against adulteration (q.v.). For a more extended description and classification of foods see the article NUTRITION.

Food of Plants. See PLANT FOODS.

Food-poisoning, a form of poisoning from food, which in times past was thought to be extremely common, but at the present time is known to occur but rarely. One of the most important features in food-poisoning is individual idiosyncrasy. It is well known that certain foods, such as strawberries and tomatoes, affect susceptible people uncomfortably, but instances of this are rare, and are often of mental origin. Epidemics of food-poisoning have occurred, as when, for instance, a baker has used a yellow coloring matter in his cake to obviate the necessity of using eggs, which coloring matter was largely made up of lead.

Food-poisoning may be classified under three main types: (1) Poisoning by means of metals; (2) poisoning by means of animal parasites; (3) poisoning by means of plant parasites, bacteria and fungi and allied organisms. The metals which have been known to cause poisoning in food are particularly arsenic, lead, copper, antimony, tin, and zinc. During 1900 there was a widespread epidemic from poison by arsenic, in Manchester, England, and neighboring cities, from the drinking of beer. On investigation it was found that the arsenical poisoning, which in some cases proved fatal, was due to the glucose used in the manufacture of the beer. This glucose had been prepared by a sulphuric acid which had in turn been made from iron pyrites containing large amounts of arsenic. It entered into the glucose, and thus became an ingredient of the beer. This epidemic was extremely severe, thousands of cases of arsenical poisoning having been observed. Lead-poisoning very frequently follows the use of water which has been conveyed through new lead pipes. It may also result from the use of leaden coloring matters used in bread, biscuit, cake, etc. Zinc and copper poisoning have resulted from the use of canned vegetables, copper frequently being used to impart a good color to the vegetable.

Food-poisoning resulting from animal parasites or from animal poisons are of extreme interest. Trichinosis from the flesh of hogs, which has been imported in pork and pork sausages, while rare in this country, is common among those people who habitually eat their sausages without thorough cooking. A form of poison results from the eating of mussels which have developed the ptomaine mytilotoxine, and similar forms of poisoning from decomposition products in meat have been observed. A special form of meat-poisoning, botulism (q.v.), is extremely common in certain countries. It seems to be due to the development of the *Bacillus botulinus*. This form of poisoning has been observed in those who have eaten ham. The symptoms are late in onset; from 24 to 36 hours after eating gastric pains with frequent vomiting occur; and constipation is at first obstinate. Practically all the cases of botulism have shown eye-symptoms. There is disturbance of vision, the eyes become fogged, the lids droop, people see double, and there is dilatation of the pupils, while burning thirst and constriction of the throat are frequent signs. Extreme muscular weakness with perhaps loss of ability to speak, or of power to empty the bladder, may develop.

Other forms of food-poisoning have been described resulting from eating sausages and other meats which were diseased at the time of killing, or which have become tainted afterward, and a number of poisonous bacteria have been isolated. *Bacillus enteritidis, Bacillus morbificans, Bacillus breslaviensis, Bacillus Friedebergensis*, have been some of the forms that have been obtained in poisonous meat. Fish-poisons are not unknown, and in Russia and Switzerland and the West Indies a number of cases have been described as resulting from fish-poisoning. A peculiar type of poisoning from milk, ice-cream, cream-puffs, frozen custards, and cheeses is known. This poison seems to be due to the presence of a toxic substance which has been named by Vaughan of Ann Arbor, Mich., as tyrotoxicon.

As to poisoning from vegetable foods, the most important general poisons are those due to eating the poisonous mushrooms, and the grains affected by ergot and allied species. Thus ergotism as found in Russia, Spain, Italy, and its close ally pellagra are types of this form of food-poisoning. A well-known disease in eastern Japan and neighboring parts of Asia, termed beriberi (q.v.), is thought to be due to poisonous rice. See FUNGI; MUSHROOM; PTOMAINES; TOXICOLOGY.

Food Preservation is the method adopted for the preservation of organic substances used as food, either animal or vegetable, and may be considered under the following heads: (1) Preservation by cold; (2) Preservation by drying; (3) Preservation by salting; (4) Preservation by smoking; (5) Preservation by sterilization by heat and the exclusion of air; (6) Preservation by chemical or antiseptic substances.

1. *Cold.*— The application of cold for the preservation of meat and vegetables may now be conducted under modern methods of applying this agent, at temperatures varying from 0° F. (—18° C.) to 40° F. or more. In the large cold storage plants now established in many cities, in which ammonia is chiefly used for the production of variable degrees of cold, it is customary to provide several large chambers for the preservation of food in which different temperatures are required, fruit being kept at temperatures a little above the freezing point, and meats, fowl and especially fish at considerably lower temperatures.

In densely settled countries like England, where the land is insufficient to produce the necessary amount of meat for the food supply of the people, frozen meat from other countries forms a very large part of the food supply. If the meat is frozen before *rigor mortis* (rigidity following death) supervenes the meat keeps well, but if it is frozen later it rapidly decomposes after thawing. Freezing arrests putrefaction and has a tendency to conceal the odor of decomposition. Hence the bad condition of frozen fish may not be detected until the heat necessary for cooking is applied. Meat which has been frozen, is often unusually tender, on account of the loosening of the intermuscular tissue by freezing; bacteria can more readily penetrate into the interior of the thawed meat, and bring about rapid decomposition. Such meat and fish, especially when thawed too suddenly, lack the flavor of fresh meat. Bacteria in general and especially those which are concerned in the production of putrefaction, seem to be endowed with extraordinary powers of resistance to the action of cold. Colemann and Mickendrick kept flesh six hours in hermetically sealed boxes at temperatures from —6° to —130° C., but in every instance the flesh after being kept at a slightly warm temperature began to decompose in from 10 to 12 hours, though protected from subsequent infection. But cold, though it may not destroy micro-organisms, prevents their development, or at least does so in the case of putrefactive bacteria. There are, however, certain bacteria which are capable of developing in frozen meat, and especially in that which is kept at about 0° C. Lafar attributes to this cause, the unpleasant flavor sometimes acquired by meat which has been kept in a refrigerator for several days. This is confirmed by Popp, who says that the walls of such ice chambers when moist, swarm with bacteria, which in his opinion produce the objectionable flavor often developed in stored meat.

The Detection of Frozen Meat.— Maljean describes a method of detecting frozen meat by microscopic examination of the blood of the meat. A drop of the blood is expressed from the meat upon a glass slide, covered with a thin glass, and examined as soon as possible to avoid solidification. The juice of fresh meat shows numerous red corpuscles of normal color and shape floating in a nearly colorless serum. But the corpuscles of frozen meat are more or less distorted in form and are completely decolorized, while the surrounding fluid is relatively dark in color. On placing a fragment of frozen meat in a test tube, containing some water, the liquid becomes colored more rapidly and intensely than when fresh meat is used.

2. *Drying.*— This is one of the oldest and best known of the various processes of preservation, and applies equally to animal and to vegetable products. By this means, beef and fish of many kinds, grapes, figs, apples, peaches, currants, and many other kinds of fruit are annually preserved by drying, and are thus rendered more suitable for transportation to distant markets, in consequence of great reduction in weight, as well as preservation from decay. The more rapidly the drying process is conducted the better. Drying is conducted in the open air by the aid of the sun's heat, or by artificial means. The curing of fish by drying constitutes an important industry in most northern maritime countries, the principal edible fish employed for this purpose being cod and herring, of which large numbers are dried in the fishing ports of the Atlantic coast north of Cape Cod, and in the British Islands and on the coast of Norway and Sweden. Fish are prepared for drying by the removal of the entrails, slitting them lengthwise, and then drying them in the open air.

3. *Salting.*—Salting is one of the oldest and best-known methods of preserving meat and fish. The most common method of preserving meat, especially pork, is by placing the meat in casks in layers, with salt between each layer. The salt withdraws water from the meat, and the brine thus formed penetrates the fibres of the meat. In Eckart's Munich quick-salting process, the meat is impregnated under pressure with a 25 per cent solution of common salt for 24 hours and then smoked. It is claimed that by this process the loss consists, mainly, of only water and a little phosphoric acid, that the meat has a better flavor, and that trichinæ are completely destroyed. As one of the results of salting meat is the removal of its natural color, it is quite customary to add a small quantity of saltpetre to counteract this effect. According to Lehmann, a small percentage only should be used on account of its harmful effect. Five grams of this salt have caused severe illness and eight grams have been known to cause death. The effect of the continued use of meat containing saltpetre, upon the human system, has not been determined by observation or by experiment.

Influence of Salting Upon Bacteria.— Forster's experiments show that the streptococci of erysipelas and many other well-known bacteria can live for weeks and even months in salted meat. The bacilli of tuberculosis retain their virulence for more than two months, and while the bacteria of anthrax perish in less than a day, their spores retain their vitality for a much longer period.

Effect of Salting Upon Flesh.— Salted meat is harder and more difficult of digestion than fresh meat. Voit shows by analysis that the nutritive value of meat is only slightly diminished after 14 days' salting. He found the percentage loss to be for water 10.4, organic matter 2.1, albumen 1.1, extractives 13.5, phosphoric acid 8.5. The amount of salt taken up by 1,000 grams of fresh meat was 43 grams. Polenske, on the contrary (Jahresbericht Nahr. u. Genussmittel 1891, p. 40), found that the meat, after being salted for three weeks lost 7.7 per cent of its nitrogenous constituents, and 34.7 per cent of its phosphoric acid, and after three months and six months the loss was still greater. He therefore concluded that the meat was greatly altered in its nutritive character, and that it could not be used continuously without injurious effects. Salted pork constituted a very important part of the food ration of the Union army in the Civil War, and when accompanied with an abundant supply of fresh vegetables, it was considered a wholesome article of food. Absence of the latter, however, was often the cause of serious illness. Strohmer gives the following analysis of fresh and salted herring:

	Fresh herring	Salt herring
Water	80.7	46.2
Nitrogenous substances	10.1	18.9
Fat	7.1	16.9
Ash	2.1	16.4
Salt	....	14.0

Caviare.— This is the salted roe of the sturgeon and other fish. It is prepared by washing the roe with salt water, leaving it in the brine for some time, pressing it, again treating it with salt water, passing it through a hair sieve, and finally packing it in salt. The most highly prized is the Astrakhan caviare, which is prepared at the mouth of the Volga. The following analyses of caviare are compiled from the works of Gobley and of König:

	Caviare	Pressed caviare
Water	43.89	30.89
Nitrogenous substances	30.79	40.33
Fat	15.66	18.90
N-free substances	1.67	....
Ash	8.09	9.88
The dry substance: N-substances	54.89	58.36
The dry substance: Fat	24.02	27.35
The dry substance: Nitrogen	8.78	9.36

4. *Smoking.*— The preservative qualities imparted to meat or fish by smoking are due partly to the drying action of heat, and partly to the antiseptic action of some of the substances of which smoke is composed, namely, creosote, formaldehyde, and pyroligneous acid. The smoke coagulates the albumen of the meat, and forms a protecting envelope. The best woods for the production of such smoke for preserving are beech, birch, and poplar, the conifers being unsuitable in consequence of the resin which they contain. There is no loss of nutriment, and Strohmer found that smoked meat is as digestible as fresh meat. Smoking may be con-

ducted in two ways: (1) by slowly smoking the meat for 24 hours at 25° C., or in the case of sausages and fish at 70° C., and then for a short time at 100° C.; (2) the meat may be placed directly in the hot smoke. Products prepared by the slow process have been found to contain more micro-organisms than those made more rapidly. The smoking should be continuous and not intermittent.

Action on Bacteria.— Serafini and Ungaro found that smoke acts energetically on pure cultures of bacteria, those of anthrax being killed in 2½ hours, and anthrax spores in 18 hours. Bacilli in the interior of the meat were not killed. Forster found the bacilli of tuberculosis still virulent in the interior of meat after it had been salted and smoked.

The following analyses of smoked and salted meats and fish are from the works of Strohmer and König:

	Water	Nitrogenous substances	Fat	Ash	Common Salt
Ham	59.73	25.08	8.11	7.08	....
Smoked beef...	47.68	27.10	15.35	10.59	....
Smoked herring	64.49	21.12	8.51	1.24	....
American bacon	9.15	9.72	75.75	5.38	....
Mackerel	44.45	19.17	22.43	13.82	11.42
Salmon	51.46	24.19	11.86	12.04	10.87

During the process of salting and smoking the coloring matter of meat is changed, as shown by the spectroscope. Smoked ham and other meats have an alkaline reaction.

5. *Preservation by Exclusion of Air After Sterilization by Heat.*— In early times food was preserved to a limited extent by heating in earthen vessels, and sealing hermetically by such crude processes as were available. At the present day such methods have given place to preservation, either in tin cans or boxes or in glass. In the former instance food may be preserved for long periods, by means of soldering, and in the latter by means of tight-fitting joints and rubber rings. The latter method is not so much used in trade, but is largely employed for domestic purposes. The prudent housewife also makes use of surface layers of paraffine and waxed paper for the temporary exclusion of air. Tin cans are stronger, and more tight, and more economical. Almost every kind of perishable food is now preserved in this manner.

In the United States the preservation of meats, poultry, fish, vegetables, and fruits in this manner has become an important industry and branch of commerce, both domestic and international. The canning of meats is conducted to a great extent in those cities where great slaughtering establishments are located. The canning of vegetables and fruits is carried on at places located among the great fruit-producing regions, while the fish canneries are mostly upon the rivers and in the seacoast towns of the northeast and northwest States and Provinces where the fish are taken from the water. The cans filled with their contents are either heated in steam retorts or immersed in boiling water. A small hole is left in the cover, and while still hot, the hole is closed with a bit of solder. In a few days the cans are tested by tapping them with a wooden mallet or hammer. If the cap sinks slowly, the can has been properly sealed, but if it is elastic, and springs back, it is rejected as a "swell-head." In the preservation of corned beef, the cans are pierced to allow the water and fat to escape, and are then soldered and placed in boiling water again for several hours.

Canned roast beef is largely used as a part of the army and navy ration, especially during the time of war, and upon the frontier. The method of preparation is thus described by Munson: "The beef is first placed in water and maintained at a temperature of 95° C. until well cooked. It is then removed, trimmed and placed in cans, a little gelatine being added to bind the meat together. The cans are then sealed and either submerged in boiling brine, or placed in superheated steam at 125° C. The steam in the can escapes through a puncture made in the top of the can which is immediately afterward closed with solder. The meat being sealed while hot, any portion of enclosed space is a partial vacuum; consequently a good can of meat will usually present a concave appearance on the outside, from atmospheric pressure.

When a can is bulged it is bad — unless frozen — and should be rejected. Freezing causes a bulging of the ends of the cans without injury to their contents. The ends, after the contents are thawed, return to their former shape, unless this process has been several times repeated.

The process of canning involves the making and soldering of two punctured holes in the top of each can. The presence of three such holes is evidence that the can had been imperfectly treated, and that it was reheated, the gas allowed to escape and the hole punctured for this purpose again sealed. The contents of such reheated cans are more likely to be of inferior quality than those of properly prepared cans. On this account the packers are careful to make the third puncture as inconspicuous as possible, and often to conceal it entirely by making it on the side of the can near the top and pasting the label over it. This may usually be detected by running the finger around the rim of the can.

Sometimes newly packed cans are so much swollen that reheating is not sufficient. In such cases the cans are opened, the contents sorted and the sound parts repacked in cans as before. The quality of such articles can only be determined by opening the cans and examining their contents, which present an overcooked appearance. First-class canned goods have the name of the manufacturer and often that of the wholesale house through which they are sold upon the labels, while doubtful goods have a fictitious factory name and no dealer's name.

Canned peas are subject to great variations in quality. Dried peas are bought in large quantities, soaked, heated and canned. Such articles can usually be recognized by their appearance and taste on opening the cans. To such an extent is this done as to have led to legislation in some States requiring all such cans to be legibly marked "soaked."

French canned peas and beans are often colored with sulphate of copper, which improves their appearance, but not their taste. The sale of such articles is forbidden in some countries.

The Composition of Canned Meats.— König found the following results in samples of canned meats and salmon. From 48 to 65 per cent of water, from 15 to 33.8 per cent of nitrogenous substances, from 0.2 to 21.6 per cent of fat, and from 2.3 to 21 per cent of ash. Of the water-free substances, there were from 43 to 78 per cent of nitrogenous substances, and from 0.3 to 43 of fat. The albuminous substances were generally less than those of fresh meat, the actual figures varying in different kinds of meat, from 87.06 to 93.94 per cent as much as that of fresh meat. The preservation of food by hermetic sealing in cans has, within the last half century grown to be an important factor in the commercial and industrial development of the United States. Before 1795 drying and the use of salt and sugar were the only methods used to any considerable extent in the preservation of food. Nicholas Appert, a Frenchman, stimulated by the offer of a reward for a mode of preserving food for use at sea in the navy, submitted to his government a treatise upon the hermetic sealing of all kinds of food. His principle, as set forth in this work, was practically the same as that which is now in use, the exclusion of air, and the application of heat for the purpose of sterilization. France first purchased his process and the industry soon spread to England and Ireland.

One of the first persons who introduced the industry into the United States was Ezra Daggett, who arrived in New York between 1815 and 1818. In 1819 he was engaged in the manufacture of hermetically sealed goods, chiefly salmon, oysters, and lobsters. William Underwood arrived at New Orleans from London in 1817, having learned the trade of pickling and preserving with the house of Mackey & Company. Not liking the climate of the South he walked from New Orleans to Boston, where he and Charles Mitchell introduced the same industry, applying it to pickles, sauces, jams, and fruit. Glass jars were at first used, but on account of their expense and fragile nature, they were soon largely supplanted by tin cans, which were introduced in 1825 by Thomas Kensett. The making of tin cans for this purpose became an important industry, various improvements being made from time to time in the processes of manufacture.

During the Civil War large quantities of canned meats, tomatoes and other vegetables and fruits were furnished both to the army and to the navy, and during the Spanish war the use of preserved meats treated with chemical antiseptics at one time threatened to become a lively campaign issue.

According to the census of 1900 there were in that year 2,195 establishments for the canning and preserving of fruits and vegetables, fish and oysters in the United States, having an aggregate capital of $48,497,978. The value of their products was $82,592,196. The number of wage-earners averaged 52,581, and $12,910,399 were paid for wages. Of the total capital, $27,743,067 was devoted to the canning of fruits and vegetables, $19,514,215 to fish, and $1,240,696 to oysters. The exports of canned or preserved fish, fruits, and vegetables in 1900 exceeded the imports by about $2,500,000.

The capital devoted to the canning of fruits and vegetables had increased from $2,335,925, in 1870, to $27,743,067 in 1900, and the number of establishments from 97 to 1,808.

The number of establishments in the New England States in 1900 was 80, in the Middle States 945, in the Southern States 204, Central 380, Western 28, Pacific 171. The largest numbers in single States were in New York 511, Maryland 271, California 136, Michigan 98, Virginia 88, New Jersey 73, Ohio 70, Illinois 61, Indiana 60, Maine 59, and Delaware 51. The value of the products was, in California $13,081,829, in Maryland $11,996,245, in New York $8,975,321 and in Illinois $3,730,030. The principal preserved fruits and vegetables in value were tomatoes $13,926,749 (641,219,993 pounds), corn $8,230,975, peas $4,679,426, beans $2,124,208, peaches $4,414,277, pears $2,233,166, apples $1,160,728, apricots $1,591,567, dried apples $1,913,142, dried prunes $970,927, and raisins $720,268.

The drying of fruit is confined chiefly to California and New York, these States reporting 87.2 per cent of the total number of pounds. Maryland leads in oyster canning and is among the first in the canning of tomatoes, corn, peaches, peas, lima beans, pears and pineapples. Maine is the leading State in sardine canning, and New York leads in canning corn, apples and pears.

Fish Canning and Preserving.— The number of establishments devoted to fish canning and preserving in the United States in 1900 was 348, having increased from 110 in 1890. Of the total number in 1900, 117 were in Maine, 61 in Massachusetts, 36 in Alaska, 36 in Washington, 24 in Oregon, and 19 in California. The value of products in 1900 was $22,253,749, of which Maine produced $4,779,733, Washington $4,831,038, Alaska $3,821,136 (or more than half the amount paid Russia for this territory), and Oregon $1,788,809.

By far the greatest capital employed in any single city in fish preservation was in Gloucester ($1,479,647), and secondly in Seattle, Wash., $336,620.

The canning of fish was introduced at Eastport, Maine, in 1843, lobsters and mackerel being preserved in this manner. Establishments for salmon canning were started on the Columbia River in 1866, and at Klawak, Old Sitka and Cook Inlet in Alaska in 1878 and 1882. The labor in these salmon canneries is chiefly performed by Chinese. The sardine canning of Maine is next in importance to the salmon canning of the Pacific coast. Sardine is a general term applied to various small fishes, the best known being the young of the pilchard (French) and the young of the sea-herring (coast of Maine). The fish are first fried in oil, and then placed in a can with oil. Olive oil or peanut oil are chiefly used in France for this purpose, and cotton-seed oil in Maine.

The number of establishments engaged in oyster canning in the United States in 1900 was 39, of which 16 were in Maryland, 6 in Florida, and 4 in Mississippi; $1,240,696 in capital was devoted to this industry, and the products were valued at $3,670,134, of which two thirds were produced in Maryland. In canning oysters in large quantities, steam is employed, the oysters being put into a steam-tight box and submitted to the action of steam for 15 minutes, by which process they are more readily opened and made ready for canning.

The extent and importance of the food canning industry of the United States may be estimated by the fact that 400,000 persons are employed in the work of canning, manufacture of cans, packing boxes, etc. It would require 60,000 freight cars to transport a year's product: 750,000,000 cans, 2,000,000 boxes of tin plate for the cans, and 30,000,000 wooden packing boxes.

6. *Preservation by Chemical Substances.*—For many years it has been the custom to employ salt, sugar, alcohol, and saltpetre for the purpose of preserving meat and fish, and some of these substances for the preservation of fruits and vegetables, and no objection has been made to this practice; but in more recent times, and since preserved food has come into more general use, the practice of using other substances has also largely increased. The question whether the use of such articles for this purpose may be injurious to the health of the consumer does not appear to have been yet satisfactorily settled. The experiments of Tunnicliffe and Rosenheim would appear to show that food mixed with boric acid and borax, taken separately and together in such quantities as are ordinarily employed, may be eaten with impunity, but earlier observers have arrived at contrary conclusions. On account, therefore, of the possibility of the use of such chemicals in the preservation of food by persons wholly unacquainted with their physiological properties, legislation appears to be tending in the direction either of prohibition of the use of chemical preservatives or of regulating their use by making their presence known to the consumer. Many substances have been experimented upon with reference to their preservative quality, among which are sulphur dioxide, sulphites and bisulphites, boric acid and its compounds, fluorides, chlorides, alum, lime, sodium carbonate, formaldehyde, benzoic and salicylic acid and their compounds. At the present time boric acid, salicylic acid, and formaldehyde appear to be most frequently used.

Boric acid is most often used for the preservation of meats, certain kinds of fruits and catsup, and upon hams and fish. The latter are found to keep longer if the boric acid is rubbed over the outside. Two grams per kilo is sufficient for fish. According to le Féré boric acid is eliminated slowly from the system, having been detected in the urine 40 to 50 days after it had been taken. It does not appear to interfere seriously with digestion so far as could be concluded from experiments. Cases of flesh poisoning have been reported from Switzerland, where meat had been preserved with borates, which had not acted sufficiently as preservatives, but had only masked incipient putrefaction.

Sulphur and its compounds have been used to some extent for the preservation of food, but not so much at present as formerly. These compounds and especially sulphur dioxide have a powerful germicide action. Authorities differ as to their physiological action. Polli found that 8 to 12 grams of sulphite were not injurious to adults. Ostertag, Bernatzik, and Braun found that one gram of magnesium sulphite caused disorders of the stomach in women. Fischer found that 50 per cent of the preserved meat products sold in Breslau in 1895 contained sulphites, the quantity of sulphur dioxide varying from .34 to .01 per cent. According to Riche, sulphurous acid and its salts, especially calcium bisulphite, have a considerable action on meat, altering its normal condition. This action causes changes in the soluble proteid substances. An addition of 1 per cent of a sulphite to meat is not perceptible to taste or to smell. On cooking the meat the sulphite is only partially decomposed and expelled. Fischer states that meat containing more than 0.1 per cent of sulphur dioxide should be regarded as injurious to health.

Salicylic acid is one of the constituents of many of the modern meat preservatives. Bersch placed a portion of the flesh of a recently slaughtered animal in a concentrated aqueous solution of salicylic acid, and found that after four days the exterior of the meat was perfectly sound, but the interior showed signs of putrefaction, and contained many micro-organisms. He therefore concluded that the preservation of fresh raw meat by salicylic acid was not practicable. In such meat compounds as sausages and potted meat, where the salicylic acid is uniformly distributed through the mass, its germicidal properties would obviously exert a more decided action. On account of its decided taste it cannot be used so freely in meat preparations as in other kinds of food in which the taste of the preservative is concealed. Here again authorities differ as to the action of this preservative on the human economy, when used in connection with food substances. The Paris Academy has forbidden even the least addition of salicylates to food, on account of their liability to injure the kidneys or digestive organs, when any weakness of these organs exists.

Formaldehyde.— In recent years formaldehyde has been introduced as a preservative in consequence of its powerful antiseptic action. A proprietary preservative known as "Carnolin" consists of a 1.5 per cent solution of formaldehyde slightly acidified. It exerts a decided antiseptic action on milk in very small amounts. The effect of salicylic acid upon the system, when employed in the small proportions required for food preservation has not yet been well determined, but its power of forming insoluble compounds with proteid substances, and its hardening power upon animal tissues, would seem to render meat treated with it much less digestible than otherwise. Mahery and Goldsmith found that formaldehyde in the proportion of 0.2 gram limited the artificial peptic digestion of blood fibrin. Ludwig states that formalin is not applicable to the preservation of meat products. Ehrlich tried the effect of an 8 per cent. solution of formaldehyde on various food substances. He found that horseflesh was completely preserved by it, but that the odor developed was such that the meat could not be eaten. Beef thus treated did not develop this odor, but was only fit to be eaten for a short time after addition of the preservative, on account of the chemical changes which it produced. According to Bloxam formaldehyde causes fish to become so hard as to be unsalable even if the solution contains only one part in 5,000.

British Investigation Relative to the Use of Preservatives.— A committee was appointed in 1899 to report to Parliament upon the "Use of preservatives and coloring matters in food," the object of the investigation being to ascertain:

1. Whether the use of such materials, or any of them, for the preservation and coloring of food, in certain quantities, is injurious to health, and if so, in what proportions does their use become injurious?

2. To what extent and in what amounts are they used at the present time?

This committee held many hearings and examined 78 witnesses, among whom were the principal experts in England, physicians, health officers, chemists, grocers, dairymen, and representatives of different food interests.

The committee reported that the preservatives found in use other than alcohol, oils, vinegar, salt and sugar, were boric acid and other boron preservatives, sulphurous acid and sulphites, fluorides, salicylic acid, benzoic acid, and formalin or formaldehyde. A list of 4,251 articles of food examined at the government laboratory for preservatives was presented, of which 1,659, or 39 per cent, were found to contain preservatives. These consisted of 35 different kinds of food and beverages. The articles in which the greatest ratio of preservatives was found were lime and lemon juice, 88.5 per cent, ham 82.7 per cent, cream 77.9 per cent, margarine 74.4, pork-pies 70.8, cordials 70.8, bacon 70.5, sausages 66.4, fruit syrup 65.2, butter 57.1.

Of the 1,659 samples treated with preservatives, 1,249 contained boron compounds, 320 salicylic acid, 20 formalin and 143 sulphites.

The committee were of the opinion that preservatives should not be used in milk, since the milk producer might be liable by such use to protect himself against the immediate results of scrupulous cleanliness. Under the influence of preservatives milk may be exposed without sensible injury to conditions which would otherwise render it unsalable. It may remain sweet to the taste and smell, and yet may contain disease germs of various kinds, whereof the activity may be suspended for a time by the action of the preservative, but may be resumed before the milk is digested.

The following were the general conclusions of the committee, so far as preservatives are concerned:

a. That the use of formaldehyde or formalin or preparations thereof, in food and drink be absolutely prohibited, and that salicylic acid be not used in a greater proportion than one grain per pint of liquid food, and one grain per pound of solid food; its presence in all cases to be declared.

b. That the use of any preservative or coloring matter whatever in milk offered for sale in the United Kingdom be constituted an offense under the food and drug acts.

c. That the only preservative which it shall be lawful to use in cream be boric acid or mixtures of boric acid and borax, and in amount not exceeding 0.25 per cent expressed as boric acid, the amount of such preservative to be notified by a label upon the vessel.

d. That the only preservative permitted to be used in butter and margarine, be boric acid, or mixtures of boric acid and borax, to be used in proportions not exceeding 0.5 per cent expressed as boric acid.

e. That in the case of all dietetic preparations, intended for the use of invalids or infants, chemical preservatives of all kinds be prohibited.

The following statement appears in the 33d annual report of the State Board of Health of Massachusetts (1901). Out of 7,323 samples of milk examined with special reference to the presence of preservatives, 184, or 2.5 per cent, contained formaldehyde; 42, or .6 per cent, contained boric acid, and 7 contained carbonates. These samples were all obtained in the summer months.

Legislation Relative to the Use of Preservatives.— At present Austria has no law upon this subject. In Belgium the use of preservatives in milk is forbidden. In Denmark a law of 1897 prohibits the use of all preservatives except salt in butter and margarine. The use of several specified preservatives in wine is also forbidden. In France the sale of food containing either salicylic acid or formalin is prohibited. In Germany, by a law of 1879, spoiled goods sold in a state concealing their real condition make the vendor liable to a penalty. The addition of alum, boric acid and salicylic acid to wine is also forbidden. The following conclusions have been reached by the Imperial Health Board of Germany regarding the use of sulphurous acid in mince meat:

1. From fresh butcher meat without chemical preservatives, but with due observance of cleanliness, mince meat can be produced, which, if kept at a low temperature, will retain its natural color for more than 12 hours.

2. The addition of preservatives which contain sulphurous acids and similar salts can improve the natural color of the meat, but not the meat itself. By their means mince meat can appear to be of better quality than it really is.

3. The frequent consumption of mince meat which is treated with sulphurous acid salts may be injurious, particularly to people of delicate health.

The Imperial Health Board is also carrying on a series of experiments relative to boric acid and its compounds.

There is no law in Norway prohibiting the use of preservatives in food, unless they can be shown to be injurious to health. In Switzerland each canton acts for itself and there is no general law upon the subject.

Legislation in the United States.— At present there is no law of the general government upon the subject. In the report of the secretary of agriculture in 1899 were the following suggestions:

"It is not regarded as a wise thing to absolutely prohibit the use of preservatives in food. Since, however, all chemicals which have the property of preserving food have also a tendency to interfere with the process of digestion, it is held to be imperative that no food should be offered for sale which contains a preservative without having this fact plainly stated upon the label of the package. Not only should the label state that the food product contains a preservative, but it should also give the name of the preservative, and the quantity employed. In this way the intending purchaser is fully informed in regard to the character of the product which he buys. While it has been established that a healthy stomach can from time to time receive with impunity food containing small quantities of preservatives, it is by no means certain that the continued practice of ingesting preservatives in foods would not produce serious injury. On the other hand, it is also quite certain that weak or diseased stomachs may suffer temporary or permanent injury from minute quantities of preservatives. See Adulteration.

In the different States of the Union there is very little uniformity in the legislation relative to the use of preservatives in food, many States having no laws whatever upon the subject.

In Minnesota by a law of 1899 the sale of milk, cream or food products of any nature whatever "to which has been added any preparation in powdered or liquid form, known as preservatives, except salt in butter" is forbidden. In Nebraska the sale of cider containing preservatives is forbidden. In New York the use of certain preservatives in wine is forbidden. In North Carolina the name of any preservative "must be made clearly known by conspicuous labeling, or made known to the purchaser when the article is not capable of being labeled." In Ohio the use of salicylic acid or any other antiseptic in wine is forbidden. In Oregon the use of preservatives in butter is forbidden. In Pennsylvania refrigeration is the only allowable mode of preservation for fresh meats. Canned meats, pickled and salted meats and meat extracts must contain no other preservatives than salt, sugar, spices, vinegar, smoke, or saltpetre. In South Dakota no preservatives are allowed in jellies or meats. In Utah they are forbidden in milk. In Washington certain drinks as well as cream and milk must not contain salicylic, benzoic, or boric acid. In Wisconsin, the use of any preservative is forbidden in milk, cream and catsup. See ADULTERATION; FISH AS FOOD; FOOD; MEAT; MILK; REFRIGERATION, etc.

Foods for the Sick. See SICK, FOODS FOR.

Fool. See JESTER.

Fool of Quality, The, a curious novel by Henry Brooke, published originally in five volumes (1760–77). It was considered of such spiritual value by John Wesley, the founder of Methodism, that he prepared a special edition of it for the use of his followers. Toward the close of the book its mysticism becomes exceedingly exalted and visionary, suggesting the author's acquaintance with the teachings of the German mystic, Jacob Boehme. The work as a whole is hardly capable of holding a modern reader's interest. It had, however, no mean place in the popular fiction of the 18th century.

Fool's Cicely. See DOG PARSLEY.

Fool's Errand, A, a story by Albion W. Tourgee, published in 1879. It is the first of a series dealing mainly with events connected with the Civil War. "The Fool" is Comfort Servosse, a Union colonel, who removes from Michigan to a southern plantation after peace is declared. The story of his reception there and the difficulties encountered, arising out of old prejudices upon the one hand and his own training and convictions upon the other, is told with much detail and strong local coloring.

Fools, Feast of. Festivals, under this name were regularly celebrated, from the 5th to the 16th century, in several countries of Europe, by the clergy and laity, with the most absurd ceremonies, and form one of the strangest phenomena in the history of mankind. Among the heathen festivals which the Christians could not easily abolish, were the Saturnalia, which, in the confusion of all distinctions of ranks, and in extravagance of merriment, exceeded the gayest carnivals. The feast of fools, among Christians, was an imitation of the Saturnalia, and, like this, was celebrated in December. The chief celebration fell upon the day of the Innocents, or upon New Year's Day; but the feast continued from Christmas to the last Sunday of Epiphany. At first only the boys of the choir and young sacristans played the principal part in them; but afterward all the inferior servants of the Church, and even laymen, engaged in them, while the bishop, or the highest clergyman of the place, with the canons, formed the audience. The young people, who played the chief parts, chose from among their own number a bishop or archbishop of fools, or of unreason, as he was called, and consecrated him, with many ridiculous ceremonies, in the chief church of the place. This officer then took the usual seat of the bishop, and caused high mass to be said, unless he preferred to read it himself, and to give his blessing to the people, which was done with the most ridiculous ceremonies. During this time the rest of the performers, dressed in different kinds of masks and disguises, engaged in indecent songs and dances, and practised all possible follies in the church. Except from their association with the Saturnalia nothing is known of the origin of these extravagancies, which appear to have been very ancient. The most celebrated, and probably one of the most ancient of these festivals, was held in the city of Sens, in France. By an ordinance in 1245, intended to abolish it, it is alluded to as a very ancient celebration. So general was the custom of these celebrations in France, that it is said there were few towns at the end of the 17th or even as late as the middle of the 18th century, in which associations did not exist. Similar antics seem to have been played in other countries, as Germany, England, and Scotland, but it is to be hoped that the height of profanity reached in some of the extant liturgies and rubrics was not commonly attained in these fooleries. The *fête des fous* at Sens was suppressed in 1547. These fêtes were frequently prohibited, but until the Reformation period, when they were considered dangerous by the ecclesiastical authorities, they were commonly tolerated. To account for these celebrations, so opposed to all our ideas of religion, decency, and common sense, we must transfer ourselves to times when men combined, with childish simplicity, the most ridiculous with the noblest subjects, and often with less injury than we should suppose to the latter. Similarly, grotesque or indecent figures are to be seen among the sculptures of old Gothic churches, and may not unfrequently be detected in the work of the large initial letters of the breviaries and religious books of this period.

Fool's Parsley. See DOG PARSLEY.

Foot, Solomon, American statesman: b. Cornwall, Vt., 19 Nov. 1802; d. 1866. He was graduated at Middlebury College in 1826 and in 1831 was admitted to the bar, and settled in Rutland. For several terms he represented the town of Rutland in the Vermont legislature, and in 1842 and again in 1844 was elected a representative in Congress. From 1851 till his death he sat in the United States Senate where he made many important speeches, and bore a conspicuous part in the Lecompton debate of 1858.

Foot. In the human foot the bony structure is made up of three divisions, the tarsus, metatarsus, and phalanges. Seven bones form the tarsus: the os calcis or heel-bone, the largest and strongest of all, carries the principal part of the body's weight. On its posterior surface the large muscles of the calf find their attachment through the tendon Achillis. Half in front of the os calcis and superimposed upon it is the next largest bone, the astragalus. This bone bears directly the weight of the body through the large leg-bone, the tibia, resting on the upper surface. On the outer side in front of these two bones is the cuboid, and on the inner side the scaphoid or navicular bone. In front of the scaphoid there are the three small cuneiform bones, internal, middle, and external. These three bones with the cuboid form articulations with the next row or division. The metatarsus is formed of five so-called long bones; that is, each bone has a shaft and articulating extremities. To each of these is joined one of the next division or phalanges. These are also long bones, the great toe made up of two bones, and the others of three each. Strong ligaments bind these bones to one another in such a way as to form and maintain an arch from before backward, and somewhat from side to side, the points of contact with the ground being only with the os calcis behind and the metatarsus and phalanges in front — the so-called ball of the foot. By this arrangement shock is transmitted through an arch or spring, pads at these two points also further eliminating jars. The sole of the foot is also covered with small muscles, which move the toes, and tendons that flex the toes and extend the foot on the ankle. Across the dorsum or instep pass the flattened tendons that flex the foot and extend the toes. The chief artery to the sole comes down on the inner side of the heel, passing across to the outer side, then arching across to the inner side again, giving off branches to the toes. On the dorsum the main artery comes to the surface at the instep and forms an arch of supply to the toes. The nerves on both surfaces closely follow the arteries.

Among the lower animals, monkeys have feet that approach nearest to those of the human. The separation of the great toe, in a way corresponding to the thumb, and the absence of the arch are the points of difference. In many of the animals, as in the cat tribe, there is a greater or less tendency toward a rudimentary inner toe, and an increase of the function of the ball of the foot, with a lessening of the importance of the heel. In the cattle and equines the toes are fewer, and the nails or claws become converted into hoofs. The horse walks on the end of his single digit.

In measure of length, the name foot is derived from the length of the human foot, containing 12 linear inches. Square foot is a square whose side is one foot, and is therefore equal to 144 square inches. Cubic foot is a cube whose side is 1 foot, and the cube contains 1,728 cubic inches. The foot is a common measure in various countries, but its dimensions often vary somewhat. In poetry, a measure consisting of a variety of syllables, two, three, or four, in combinations of long and short, or accented and unaccented syllables. The number of possible varieties of feet is reckoned at 28. See RHYTHM.

Foot and Mouth Disease. See MURRAIN.

Foot-pound, the unit of work or of energy that is commonly used in engineering calculations in England and the United States. It is defined as the quantity of work expended in raising a weight of one pound through a vertical distance of one foot. As the attraction of the earth for a pound of matter varies somewhat in different latitudes and at different heights above the sea, the foot-pound is subject to corresponding variations as we pass from one locality to another. To give the unit greater definiteness it has been proposed to define it as the quantity of work done in raising one pound of matter through a vertical distance of one foot, at the level of the sea in latitude 45°. This definition differs from the ordinary one, it will be observed, solely by specifying the locality at which the experiment is supposed to be performed. See UNITS.

Foot-rot, a disease in the feet of sheep, the more common form of which is an inordinate growth of hoof, which at the toe, or round the margin, becomes turned down, cracked, or torn, thus affording lodgment for sand and dirt. In the second form of the disease the foot becomes hot, tender, and swollen, with ulcerations between the toes, followed by the sprouting of proud flesh. The inflammation is due to suppression of the secretion of the gland between the toes, usually the result of standing too much in wet ground. The best remedy is to pare away the diseased and ragged parts of the hoof, thoroughly applying a lotion made by dissolving one pound of blue vitriol in a quart of water, and keeping the animal always in a dry place.

Foot-wall. In mining language, the foot-wall of a vein is the rock boundary of its lower side, the side on which a miner would stand in breaking down the ore. The term is also used in speaking of a fault or rock dislocation, the foot-wall of a fault being formed by the edges of the rock strata that underlie the plane of displacement. See FAULT; MINING; ORE DEPOSIT.

Foota-Jallon. See FUTA-JALLON.

Football in America, as in England, is of different varieties, but by far the most prominent is the game played in the colleges. This type is the outgrowth of the English Rugby and still possesses points of similarity to the game from which it was derived. Association football is played in and around some of the mill towns where the foreign population predominates, and previous to 1870 a mongrel kind of football made up of a combination of Association and Rugby had some vogue, and was the original form of the sport in America.

The type, however, known as American football suggests now only one variety and that is the one mentioned above as prevailing in colleges and universities. This sport draws to each of its chief annual contests from 25,000 to 40,000 spectators. During its season, which consists of October and November, it temporarily eclipses all other athletics in interest. For this reason it is the money maker in college athletics, in a great number of universities the receipts from the football contests practically supporting the other athletic branches throughout the year.

This sport, developed as it now stands, was originally introduced into American colleges by Harvard, whose team, having visited Canada and played under the Canadian rules, became enamored of the style of the English Rugby, and, although in 1875, as a matter of consideration for her ancient rival, Yale, Harvard agreed to compromise between what was then known as American football and English Rugby, in the next year, 1876, both teams adopted the Rugby Union rules as they stood at that day. Unfortunately for the peace of mind of the legislators, but probably fortunately in another way, in that the final result was the development of still another distinct type of football, there were no traditions in America regarding the English Rugby code and what was forbidden by letter was accepted as barred, whereas anything that was not thus distinctly prohibited the American player thought was perfectly legitimate. Contentions arose over the interpretation of the rules and these discussions led to conventions, and, in the settlement of the problems arising, the rules rapidly multiplied, until in a few years there were more than twice the original number. While this was happening, some of the old English rules apparently became dead letters and were, therefore, dropped. When captains and players attended any of these conventions it was only human that they should contend for possible advantages for their own teams rather than for the improvement of the game as a sport and this led to the appointment of an advisory committee of graduates. In their hands was placed the matter of rules to this extent, that yearly they met and recommended changes which were then submitted to an intercollegiate association for discussion and usually for approval. This lasted as long as there was an intercollegiate association or league of colleges indulging in football. This league finally dissolved and for the season following there were two codes of rules in existence adopted by two different sets of universities. This was wholly unsatisfactory and led to the intervention of the University Athletic Club of New York. This club selected football enthusiasts and asked from them a recommendation as to a code of rules. These gentlemen met and framed such a code, which was then adopted by the various colleges throughout the country. This method of procedure lasted for several years, even after the dissolution of the University Athletic Club, and it is from this body that the football rules emanated, until at the end of the season of 1905 a general conference of colleges not represented upon the Rules Committee appointed seven delegates with whom the old committee amalgamated, forming a new committee of 14. This committee made the rules for 1906 and introduced what was known as the 10-yard rule, which practically did away with the old mass plays that had caused the game to become too contracted.

As for a brief description of the game and the way in which it is played, the following gives the main points:

The game is played on a field rectangular in shape, 160 feet wide and 330 feet long. The outline of this field is made by heavy white lines marked, as are the lines in a tennis court, with lime. This field is also traversed by transverse lines five yards apart marked for the convenience of the referee in judging the distance gained or lost by either side. In addition to these transverse lines the field is marked by longitudinal lines also five yards apart in order to assist the referee once more in measuring distance rapidly with his eye. This latter marking was rendered necessary by a rule providing that within that section of the field the quarter-back may run with the ball provided he goes a certain distance out, that is, toward the side line, from the man who puts the ball in play in the centre. This same five yard distance governs a forward pass. The lines which mark the ends of the field are called goal lines, and in the middle of each is a goal made by erecting two posts 18 feet, 6 inches apart with a cross bar 10 feet from the ground. The ball is a prolate spheroid in shape consisting of a rubber bladder in a leather cover.

The game is played by 11 men on a side, these 11 men being called a team. For the purpose of general distinction, although different formations are possible, the seven men who play in the forward line, that is on a line with the ball when it is put in play, are called the rushers, the men behind them the backs. The distinguishing terms for the men in the line are of interest. First there is the centre rusher, or centre, or snap-back, which term designates the man who stands in the middle of the line and usually puts the ball in play in a scrimmage. The men on his right and left are called guards, the men next beyond them towards the ends are called tackles and the two men on the ends of the line are called the ends. The man close behind the centre rusher is called the quarter-back. The two men some feet behind him are called the half-backs and the fourth man behind the line is called the full-back. In executing various plays the men take up different positions on the field, but they are usually distinguished by their positions as above.

The game is started by placing the ball in the middle of the field and a man of the side in possession must then kick it at least 10 yards into the territory of the opponents, his own men being behind him when he kicks the ball and the opponents standing at least 10 yards back from the middle line of the field. The choice of goals and the possession of the ball having been determined by the toss of a coin, the side winning has the privilege of thus either kicking off or selecting either goal. When the ball is once kicked off any man who is on side, that is, between the ball and his own goal, may secure it and run with it and when he is thus running may be tackled by his opponents and brought to a stop. If he is thus tackled and stopped he calls "down" and the ball is placed on that spot for a scrimmage. When the ball is thus down the two teams line up opposite each other, the side with the ball endeavoring to protect its men so that one of the backs may be able to secure the ball and make a run with it, kick it, or pass it, while members of the opposing side are endeavoring to break through and stop this. The men of the side which has the ball in its possession may not use their hands or arms to obstruct their opponents, but may do this with the body only. The players of the side not in possession of the ball on the other hand are privileged to use their hands and arms to break through the ranks of their opponents. The man who has the ball in his possession, that is running with it, may use his hands and arms to ward off the opponents, but the rest of his side may not. The play thus continues by a succession of downs and runs interspersed with kicks, for a side may kick or pass the ball under certain limitations instead of running with it if they so desire.

In order to prevent a side holding the ball indefinitely without making progress there is a rule providing that in 3 attempts the side must advance the ball 10 yards or surrender it to the opponents. For this reason it is quite customary after two attempts, if the desired ground has not been gained, for the side in possession to kick the ball, thus transferring it to the possession of their opponents as far into the opponents' territory as possible. One forward pass is allowed to a scrimmage under certain restrictions, and a kicked ball striking the ground puts all the players of the kicker's side «on side,» otherwise a man who gets ahead of the ball when last touched by one of his own side behind him may not touch the ball. When the ball goes across the side line it is out of bounds and if it has gone out of bounds through being kicked, it belongs to the opponents, but if a man carries it out of bounds, in his possession, his own side has the right to it. The ball is brought back to the spot where it crossed the line and is put in play by the holder walking in a certain distance and putting it on the ground for a scrimmage as already described.

The game thus proceeds until the ball approaches one or the other goal line and here begins the question of generalship for scoring. If the ball be kicked by a drop kick over the cross bar of the opponent's goal it counts the side thus kicking it four points. If the ball be carried by the player of that side across his opponent's goal line or secured by him after it has been kicked across it scores a touch-down, which counts five points and also entitles the side making it to a try at goal. This is performed either by kicking the ball out to a player who catches it and makes a mark with his heel, the ball then being kicked from any point behind that mark, or being brought directly out by a player of the side which has touched it down and held on the ground for another of his side to kick. In either event if the touch-down be converted into a goal by the kicking of the ball over the cross bar it adds an additional point for this scoring.

There is one other possible means of scoring and that is when a side is pressed by the opponents, and, instead of the opponents securing the ball, the defenders of the side secure it and either kick, pass, or carry it across their own goal-line and touch it back behind their own goal. This entitles them to carry the ball out 25 yards for a kick. The opponents stand on the 25 yard line while this kick is made. This safety, however, as it is called, counts two points against the side making it.

The game is divided into 2 halves of 35 minutes each with a 10-minute intermission, and the side which has scored the greater number of points at the end of the full period of play wins the game.

American football, while it started from the English Rugby Union rules, has developed in many directions so that the game would not now be recognizable to an Englishman. The one thing that he would see that possibly reminded him of Rugby would be that occasionally a man runs in the open field with the ball. But the various formations and the tactics adopted would puzzle him exceedingly. Like the Rugby Union, however, there is some kicking in it, but far less than in the English Association. In the English scrimmage the two lines of forwards push until the ball pops out somewhere, whereas in the American scrimmage the man in the center who has possession of the ball snaps it out with his hand whenever he is ready to do so to the quarter-back who stands directly behind him and this man passes it to some other player of his own side. This enables the Americans to carry out their very elaborate system of plays because the ball can be absolutely directed at any time to any spot. So perfect has this development become that the quarter-back gives signals for the plays by means of which signals the entire team knows exactly what man is to receive the ball and where he is to run with it when he has received it. Thus the others may assist him very materially in making his gain. Some idea of the variety of plays can be gathered from the fact that teams can without difficulty execute no less than 40 or 50 plays, each distinct from the other. It is not difficult to imagine that with this highly developed form of attack a most thorough and well-studied plan of defense is equally necessary. It is also not difficult to understand that this development on both sides has brought about specialization in the work of various players so that almost every position on the field has a distinct line of duties which its incumbent must be able to perform with skill and accuracy. The signals are quite elaborate codes, devised for easy memorizing, but at the same time sufficiently intricate and bewildering as to render the liability of discovery by the opponents very small.

In the American game the quarter-back usually gives these signals, although the captain sometimes prefers to give them himself.

The history of the game in America as in England and elsewhere has been one of discussion and opposition, the latter coming from those who believe that the sport is too strenuous. Kingly edicts were issued in the old days in England and in the United States State legislatures have been asked at various times to forbid the pastime. Yet it has lived on. In America the game has had already three great epochs as it were. The first in the eighties when the «block game» was legislated out of existence, then in the early nineties when «momentum mass» plays were excised and finally in 1906 when the ten yard rule was adopted.

A widespread public sentiment was advanced in favor of such a change in the rules as might bring about more «open play,» and it was further felt by the committee and their advisers that the rules should be so modified and the powers of the officials so increased as to eliminate to the greatest possible extent unsportsmanlike tactics, and with these ends in view the committee decided upon the incorporation of two important changes. The first of these was the adoption of the 10-yard rule together with the forward pass and on side kick. The second general change was the incorporation of rules that in some cases greatly increased the penalty for unfair tactics, and in others did away with all excuses for indulgence in certain rough plays, at the same time providing for more efficient work by officials. To make sure that the wishes of the committee were carried out in this matter, the duties of the linesman were enlarged and he was made practically an assistant to the umpire and given absolute power to deal with certain classes of fouls. A second umpire was added. The American game thus has for its conduct four officials, the referee whose duties are principally related to the progress of the ball, the umpires who have charge as it were of the conduct of the players, the linesman who acts as an added umpire, at the same time assisting the referee in the matter of measurements and time keeping. WALTER CAMP,
Yale University.

Foote, füt, **Andrew Hull,** American naval officer: b. New Haven, Conn., 12 Sept. 1806; d. 26 June 1863. He entered the navy as a midshipman in 1822, and in 1849-52 he was engaged in the suppression of the slave trade on the coast of Africa. In command of the China station in 1856, when the Chinese and English were at war, he exerted himself to protect American property, and was fired upon by the Celestials. His demand for an apology was refused and he stormed and captured four Chinese forts. In 1861 he commanded the expedition against Forts Henry and Donelson on the Tennessee and Cumberland rivers, and directed the attack on Island Number 10. In 1862 he was promoted rear-admiral. He wrote 'Africa and the American Flag' (1854).

Foote, Arthur, American composer: b. Salem, Mass., 5 March 1853. He was graduated at Harvard 1874, became a teacher of the piano and organist of the First Church in Boston and has devoted much time to composition, in which field he has been very successful, having published a cantata 'Hiawatha,' a trio in C major for piano, violin, and 'cello; suites for the orchestra; an overture, 'In the Mountains'; songs, and pianoforte pieces.

Foote, Henry Stuart, American statesman: b. Fauquier County, Va., 20 Sept. 1800; d. Nashville, Tenn., 20 May 1880. He was admitted to the bar in 1822; removed to Mississippi in 1826 and entered politics. In 1847 he was elected to the United States Senate, and in 1852 was elected governor of the State. He was a strong opponent of secession at the convention held at Knoxville, Tenn., in 1859, but when secession was an assured fact, he accepted an election to the Confederate Congress, where he opposed most of President Davis' measures.

Foote, Lucius Harwood, American diplomatist: b. Winfield, N. Y., 10 April 1826. He was educated at Knox College and at the Western Reserve University; went to California in 1853; and was admitted to the bar in 1856. He was a municipal judge in Sacramento 1856-60; and collector of the port of Sacramento 1861-5. He became adjutant-general of California in 1861, and was consul to Valparaiso, Chile, 1878-81. Appointed minister to Korea in 1882, he distinguished himself in the protection of Japanese and other foreigners in the nationalist revolt in Seoul in 1883, and received the thanks of the emperor of Japan, the Chinese government, and the emperor of Korea for his services. He resigned in 1884 and returned to California, where in 1890 he was made treasurer of the San Francisco Academy of Sciences. He has written 'Red Letter Day and Other Poems' (1882); 'On the Heights' (1887); etc.

Foote, Mary (HALLOCK), American novelist: b. Milton, N. Y., 19 Nov. 1847. In 1876 she was married to Arthur D. Foote, a mining engineer. She has published: 'The Led Horse Claim' (1883); 'John Bodewin's Testimony' (1886); 'The Last Assembly Ball' (1889); 'In Exile and Other Stories' (1894); 'The Chosen Valley'; 'Cœur d'Alène' (1894); 'The Cup of Trembling and Other Stories' (1895); 'The Little Fig Tree Stories' (1900); 'The Prodigal' (1900); 'The Desert and the Sown' (1902); 'A Touch of Sun and Other Stories' (1903); etc.

Foote, Samuel, English actor and playwright: b. Truro, England, 27 Jan. 1720; d. Dover, England, 21 Oct. 1777. From Oxford he turned his attention to the stage; tried tragic parts and failed; then began to give entertainments of a sort now familiar but then new, impersonating real and imaginary people and acting little farces by himself. He wrote many farces, the most notable being: 'The Minor' (1760), a skit at the Methodists; 'The Liar'; 'The Mayor of Garratt.'

Foote, Samuel Augustus, American statesmen: b. Cheshire, Conn., 8 Nov. 1780; d. there 15 Sept. 1846. He was graduated at Yale College in 1797; served in the legislature for many years; was member of Congress in 1819-21 and 1823-5; served one term in the United States Senate, was governor of Connecticut, and one of the presidential electors on the Clay and Frelinghuysen ticket in 1844. It was he who in 1829 introduced the bill «on the public lands» that occasioned the famous debate between Hayne and Webster.

Footmen, a collector's name for the small gray and yellowish moths of the family *Lithostidae*, which have simple antennæ, rather narrow fore wings, beneath which the broad hind wings are folded when at rest.

Foraging Ants, the large, powerful ants of the tropical American genus *Eciton,* which from time to time march in hosts across the country, with the precision of an army under the control of officers. These marching columns are composed almost wholly of workers, apparently directed by a larger, lighter-colored kind; and they search every inch of ground, rubbish-heap or thicket, searching for what they can eat and driving every living thing out of their way in terror. Several species exist, differing in various respects. One, for example, devotes its forays entirely to finding and robbing the homes of a smaller and very different ant (*Hypoclinea*), whose larvæ and pupæ it carries off, but lets the adults go free. Ordinarily no insect that can be caught is spared. These ants have no settled abode, but make nests in hollow stumps, or underground, and change them each season or oftener. Their colonies exhibit a high degree of organization, and contain five separate castes, instead of the three of ordinary ants. See ANTS, and the works referred to thereunder; and especially Belt, 'Naturalist in Nicaragua' (1888).

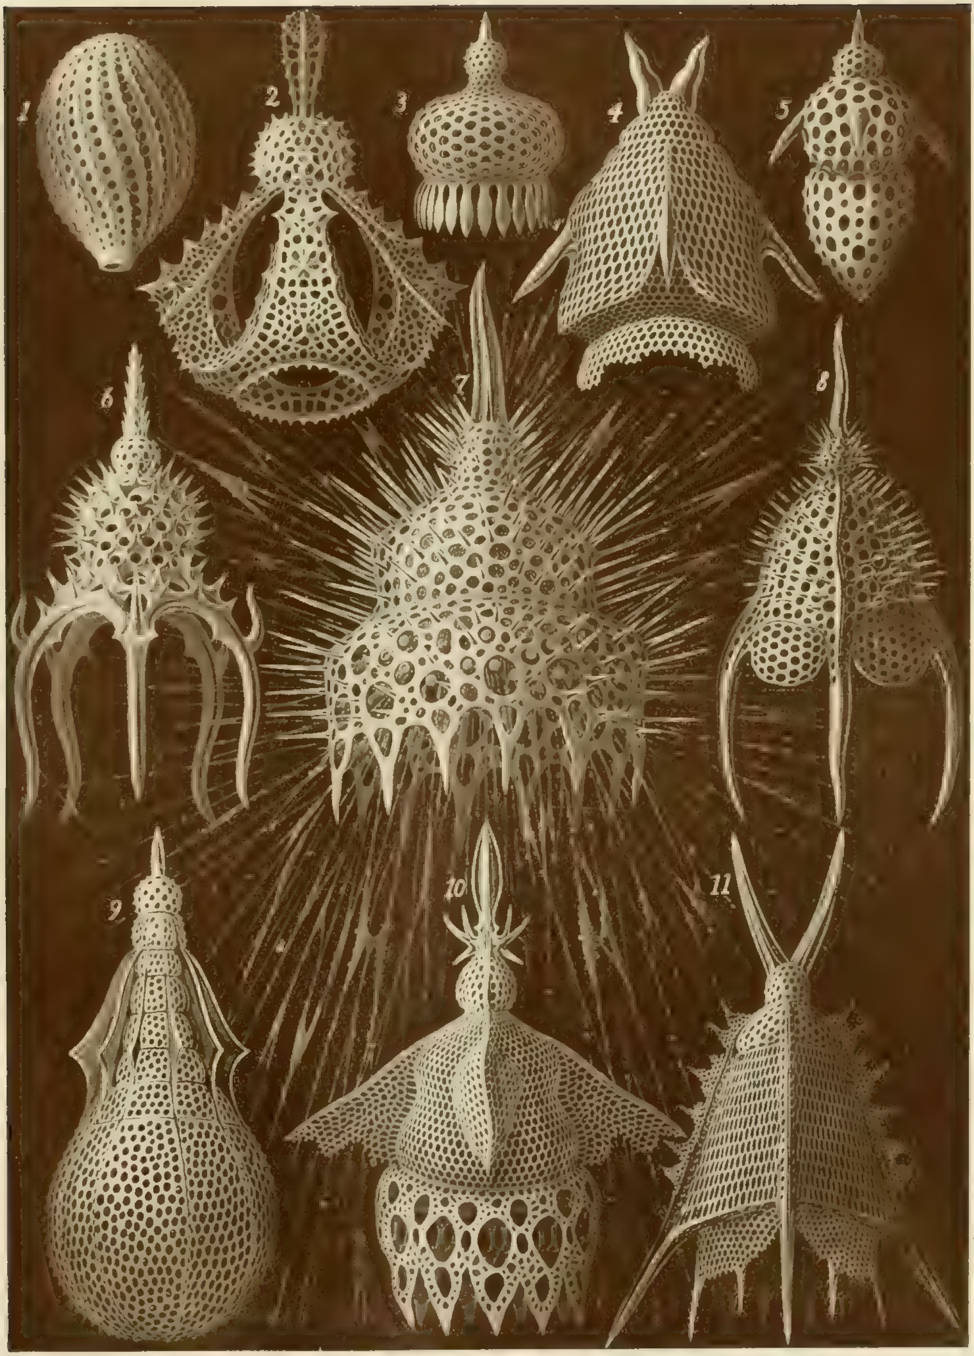
Foraker, Joseph Benson, American politician: b. near Rainsboro, Highland County, Ohio, 5 July 1846. He enlisted in the 89th Ohio infantry in 1862, participated in the battles of Missionary Ridge, Kenesaw Mountain, and Lookout Mountain and in Sherman's "march to the sea," served on the staff of Gen. Slocum, and was mustered out in 1865 with the rank of first lieutenant and brevet captain. Subsequent to the War he studied for two years at the Ohio Wesleyan University, in 1869 was graduated from Cornell University, and in the same year was admitted to the bar at Cincinnati and there began the practice of law. In 1879 he was elected judge of the superior court of Cincinnati, from which post he resigned in 1882. He was Republican candidate for the governorship of Ohio in 1883, but was defeated by Hoadly, Democrat; was elected in 1885 and re-elected in 1887; and was again defeated in 1889, this time by Campbell. In 1896 he was elected United States senator to succeed Calvin S. Brice, and in 1902 re-elected. He was chairman of the Ohio Republican State conventions of 1886, 1890, 1896, and 1900; a delegate-at-large from Ohio to the national Republican conventions of 1884, 1888, 1892, 1896, and 1900, being chairman of the Ohio delegation in 1884 and 1888; and presented to the conventions of 1896 and 1900 the name of William McKinley for nomination to the Presidency. He attained the largest law practice in southern Ohio, and became well known in that State as a corporation attorney and a vigorous orator on political questions. His election to the Senate at once made him the Republican leader of Ohio. In the Senate he took a prominent part in the discussions connected with the Spanish-American war, of which he was a conspicuous advocate. His name has been mentioned for the Presidential nomination.

Foraminif'era, an order of animals in the phylum *Protozoa* and the class *Rhizopoda.* The body is contained within a calcareous test or shell, which is many chambered. It may be cylindrical or spiral, or it may tend to the pyramidal form. The outer surface presents a punctate or dotted appearance, produced by the presence of very numerous small apertures, or "foramina." The chambers in some are perfectly distinct from others, though so aggregated as to form a compound shell; in others they are connected with a funnel-like tube. The texture of the shell in one group is porcelain-like, in another glassy. The inside of the shell has an extensile and contractile sarcode (protoplasm) of a reddish or yellow color, which streams through the openings and thinly covers the outside. Foraminifers are always of small size, and often microscopic. With the exception of *Gromia* and one or two related genera which occur both in fresh and salt water, they are exclusively marine and many dwell only in the abysses. Sometimes their shells constitute sea-sand. In the Atlantic, at a depth of 3,000 fathoms, there is an ooze composed almost entirely of *Globigerinæ,* which belong to this order. See GLOBOGERINA.

The exceedingly antique *Eozoon* (q.v.) of the Laurentian rocks, if organic, as is generally believed, was apparently a foraminifer. Forms more unequivocal, some of them very like recent species, occur in the Silurian, the Carboniferous, and other strata. They are found through all the Secondary Period, chalk (q.v.) being almost entirely composed of their cases. They increase in number and importance in the Tertiary. The flat, coin-shaped nummulites of the Middle Eocene form the principal bulk of great series of limestone rocks that furnish excellent building-stone. The type of the order has remained wonderfully constant from the earliest times till now.

Foran, Joseph Kearney, Canadian author: b. Aylmer, P. Q., 1857. Among his poems the best known are a 'Lament for Longfellow' and 'Indian Translations.' He is the author of two novels, 'Tom Ellis, a Story of the Northwest Rebellion,' and 'Simon, the Abenakis.' 'The Spirit of the Age' (1894); 'Poems and Canadian Lyrics' (1895).

Forbes, fôrbz, **Archibald,** English journalist and war correspondent: b. Morayshire 1838; d. London 30 March 1900. From 1859 till 1864 he served in the Royal Dragoons, but, abandoning the army for journalism, joined the staff of the *Daily News,* as war correspondent. In this capacity he accompanied the German army through the war of 1870–1, and a little later, in Paris, was present at the downfall of the Commune. He was in India during the 1874 famine, and shortly afterward the Carlist and other troubles kept him for a time in Spain. He accompanied the Prince of Wales on his Indian tour in 1875–6, and on returning described as an eye-witness the Servian war of 1876. In the following year he was with the Russians in their campaign against the Turks, being present at the battle of Plevna, and in 1878 he went to Cyprus. He was under fire during the Afghanistan campaign of 1878–9, next visited Mandalay, and then went to Zululand. He afterward devoted himself mainly to lecturing at home and in America and Australia. His chief publications are: 'My Experiences in the Franco-German War' (1872); 'Glimpses through the Cannon Smoke' (1880); 'Chinese Gordon' (1884); 'Souvenirs of Some Continents' (1885); 'William I. of Germany' (1888); 'Barracks, Bivouacs, and Battles' (1891); 'Havelock' (1891); 'Afghan Wars' (1892); 'Colin Campbell, Lord Clyde' (1895); 'Camps,



RHIZOPODS.

1 Cyrtophormis spirall. 2 Clathrocanium reginae. 3 Anthocyrtium campanula. 4 Pterocorys rhinoceros
5 Lithornitbium falco. 6 Alacorys Bismarckii. 7 Calocyclas monumentum. 8 Pterocanium trilobum.
9 Stichophaena Ritteriana. 10 Dictyocodon Annasethe. 11 Artopilium elegans.

Quarters, and Casual Places' (1896); 'Memories and Studies of War and Peace' (1896); 'The Black Watch' (1896); 'Life of Napoleon III.' (1898).

Forbes, David, English geologist: b. Douglas, Isle of Man, 6 Sept. 1828; d. London 5 Dec. 1876. As a civil engineer he traveled all over the world, studying rock formations and fossils, and writing: 'On the Relations of the Silurian and Metamorphic Rocks of the South of Norway' (1855); 'On the Geology of Bolivia and Southern Peru' (1861); and kindred treatises.

Forbes, Duncan, Scottish jurist: b. near Inverness, Scotland, 10 Nov. 1685; d. 10 Dec. 1747. He studied at Paris, Utrecht, and Edinburgh, and rose, in 1737, to the rank of president of the Court of Session. It was mainly owing to his exertions that the rebellion of 1745 was prevented from spreading more widely among the clans; but so ungratefully was he treated by the government, that he was never able to obtain repayment of the various sums he had expended to uphold it. He was the author of: 'Thoughts on Religion'; the 'Culloden Papers'; etc.

Forbes, Edward, English naturalist: b. Douglas, Isle of Man, 12 Feb. 1815; d. Wardie, near Edinburgh, 18 Nov. 1854. He was a brother of David Forbes (q.v.). He became professor of botany in King's College, London, in 1843, and curator of the Geological Society; in 1851 professor of natural history in the School of Mines; and in 1853 he was elected to the chair of natural history in the University of Edinburgh. He did much to advance and systematize special departments of natural history, both by his own labors and by the stimulus which he imparted to his associates and pupils. His classification of the British star-fishes opened a new era in that branch of zoology; and his discovery that air-breathing mollusks lived at the period of the Purbeck beds rectified many erroneous hypotheses. Of his separate works, papers, and monographs upward of 200 were published; among them: 'Star-fishes' (1841); 'The Radiata and Mollusca of the Ægean' (1843); 'Travels in Lycia' (1846); 'Naked-eyed Medusæ' (1847); 'British Mollusca' (1853); 'Literary Papers by E. Forbes' (1855).

Forbes, Edwin, American landscape and genre painter: b. New York 1839; d. Flatbush, L. I., 1895. He was a pupil of A. F. Tait, and became special artist for 'Frank Leslie's Magazine' during the Civil War. The drawings which he made during that time are now in the war office at Washington, and are of historic value.

Forbes, Evelina Louisa Michell, English novelist: b. Tettenhall. She was married to Hon. Walter Forbes in 1888. Her published books include: 'Fingers and Fortune' (1886); 'Her Last Run' (1888); 'Blight' (1897); 'A Gentleman' (1900); 'Dumb' (1901); 'Unofficial' (1902).

Forbes, Harriette Merrifield, American writer: b. Worcester, Mass., 22 Oct. 1856. She was married to W. T. Forbes 5 Feb. 1884. She has published: 'The Hundredth Town' (1889); 'The Diary of Rev. Ebenezer Parkman' (1899).

Forbes, James David, Scottish physicist: b. Colinton, near Edinburgh, 20 April 1809; d. Clifton, England, 31 Dec. 1868. He was admitted to the Scottish bar in 1830; in 1833 was appointed to the chair of natural philosophy in the University of Edinburgh, and in 1860 became principal of the United Colleges of St. Salvador and St. Leonard, in the University of St. Andrews. His fame rests chiefly on his study of glaciers. His chief publications on this subject are: 'Travels through the Alps of Savoy' (1843); 'Norway and its Glaciers' (1853); 'Tour of Mont Blanc and Monte Rosa' (1855); and 'Occasional Papers on the Theory of Glaciers' (1859). Forbes' theory was that glacier ice moves in its channel like a viscous fluid, the middle moving faster than the sides, and the upper portions faster than the lower.

Forbes, John Colin, Canadian artist: b. Toronto, Canada, 23 Jan. 1846. He studied at the Royal Academy, London, England, and on the continent, and returning to Canada he became a successful landscape and portrait painter. Among his works are: 'Foundering of the Hibernia'; 'The Mount of the Holy Cross'; 'The Glacier of the Selkirk'; 'The Lily'; and portraits of Gladstone, Sir John A. Macdonald, the Marquis of Dufferin, Lady Helen Blackwood, and Sir Charles Tupper.

Forbes, John Franklin, American educator: b. Middlesex, N. Y., 13 June 1853. He was graduated at the University of Rochester in 1878; and in 1885 was made president of the John B. Stetson University in Deland, Fla.

Forbes, John Murray, American clergyman: b. 5 May 1807; d. 1885. He was graduated at Columbia College 1827, and at the General Theological Seminary of the Protestant Episcopal Church 1830. He was ordained to the ministry in the year last named, and became rector of St. Luke's Church, New York, 1834. He adopted the Roman Catholic faith in 1849, and was appointed pastor of St. Ann's Church in New York shortly afterward. Returning to his earlier faith in 1859, he was restored to the ministry 1862 and was dean of the General Theological Seminary of the Protestant Episcopal Church 1869–72.

Forbes, John Murray, American merchant: b. Bordeaux, France, 23 Feb. 1813; d. 12 Oct. 1898. He entered a Boston counting room at 15 and in 1834 became a partner in the firm of Russell & Company, china merchants in Boston. He built many clipper ships for the California trade, and was later prominent in railway managements. Naushon, the largest of the Elizabeth Islands, Mass., was owned by him and constituted his summer home where many notables were entertained by him. See Hughes, 'Letters and Recollections of John Murray Forbes' (1899).

Forbes, Stanhope Alexander, English artist: b. Dublin, Ireland, 18 Nov. 1857. He was educated at Dulwich College and studied art at the Royal Academy Schools, and under Bonnat in Paris. Among his pictures exhibited at the Royal Academy are: 'The Fish Sale'; 'The Health of the Bride'; 'By Order of the Court'; 'The Salvation Army'; 'Forging the Anchor.'

Forbes-Robertson, John, English art critic: b. 30 Jan. 1822; d. London 25 Feb. 1903. He was educated at the University of Aberdeen.

went to London at 21, and after visiting various art centres devoted himself to literature and criticism. He has published: 'The Great Painters of Christendom'; and lives of Gustave Dore, Rosa Bonheur, etc.

Forbes-Robertson, Johnston, English actor: b. London 16 Jan. 1853. He is the son of John Forbes-Robertson (q.v.) and has been prominent on the English stage since he was 21.

Force, Manning Ferguson, American soldier and author: b. Washington, D. C., 1824; d. 1899. He was the son of Peter Force (q.v.). He was graduated at Harvard College 1845 and at the Harvard Law School, entering the army in the Civil War as major of the Twentieth Ohio Volunteers, and attaining the rank of brevet major-general of volunteers. He was judge of the court of common pleas of Hamilton County, Ohio, 1867–77, and judge of the superior court of Cincinnati 1877–8. He published: 'From Fort Henry to Corinth' (1881); 'Marching Across Carolina' (1883); 'Personal Recollections of the Vicksburg Campaign' (1885); etc.

Force, Peter, American historian: b. near Little Falls, N. J., 26 Nov. 1790; d. Washington, D. C., 23 Jan. 1868. His life work, entitled 'American Archives,' a valuable collection of 22,000 books and 40,000 pamphlets, was bought by the government (1867) and placed in the library of Congress. He published also: 'Grinnell Land: Remarks on the English Maps of Arctic Discoveries in 1850–1' (1852); and 'Notes on Lord Mahon's History of the American Declaration of Independence' (1855).

Force, the immediate agency by which the motion of a body is increased or diminished, or changed in direction, or by which such changes are opposed. A force is measured, in theoretical mechanics, by the increase of velocity that it can produce upon a body of unit mass, when it acts upon that body for one second. Suppose, for example, that a uniform force of magnitude F acts for T seconds upon a body of mass M, thereby increasing (or diminishing) its velocity by V units. Then the magnitude of the force is defined by the equation $F = \frac{MV}{T}$.
If M is expressed in grams, and V is expressed in centimetres per second, then F, as calculated by means of this equation, is expressed in dynes. If M is expressed in pounds, and V in feet per second, then F, as calculated from this equation, is expressed in «poundals»; the word «poundal» (for which we are indebted to Prof. James Thomson) denoting the force which will increase (or diminish) the velocity of one pound of matter by one foot per second, when it acts upon it for one second. It is known by experiment that when a body falls freely under the influence of gravity, its velocity, at the end of one second, is about 32.2 feet per second. Let the body in question have a mass of M pounds, and let F be the attraction of the earth upon one pound of matter, as expressed in «poundals.» Then the total force, F, that is acting upon the body is $F = Mf$; and hence the foregoing equation gives us, for this case (remembering that $T = 1$), $Mf = 32.2M$, or $f = 32.2$; and hence it follows that the attraction of the earth upon one pound of matter is 32.2 poundals in a region where gravity, when acting freely upon a body for one second, increases its velocity by 32.2 feet per second. If we follow the usual custom and represent the accelerative effect of gravity at any place by the letter g (instead of by the particular value 32.2), we may make the following general statement, which may also be taken as the definition of the poundal: In a region in which gravity increases the velocity of a falling body by g feet per second, per second, the earth attracts one pound of matter with a force of g poundals.

A force is said to be «central,» when it acts always toward a definite centre, which may be either fixed or in motion. The gravitative forces with which the heavenly bodies act upon one another are of this character, and are often popularly called «centripetal» (that is, «centre-seeking») forces for this reason. When a body is caused to move in a curved path, it exerts a force which acts along the radius of curvature of the path, and in a direction away from the centre of curvature. Forces of this nature are called «centrifugal» (or «centre-fleeing»), and familiar examples are afforded by the pressure of swiftly moving water against the curved vanes of a turbine water-wheel, and by the tension produced in a string when a stone that is attached to the string is whirled rapidly about in a circle. The nature of centrifugal force has been the subject of more or less controversy, some authorities maintaining that it should not be classed as a true force, since it does not produce any acceleration in the direction in which it acts; — that is, a particle on the rim of a swiftly revolving wheel does not fly off radially when it is liberated, but merely continues its motion with unaltered speed, in the direction in which it was moving at the instant of its liberation; — or tangentially to the wheel. The subject is too technical for discussion in this place, but it may be pointed out that such a particle is actually subject to a radial acceleration, if its motion is considered *relatively to the wheel.*

Forces are said to be «conservative» when the principle of the conservation of energy holds true for the systems in which they occur (see ENERGY). All of the forces of nature are believed to be fundamentally conservative, although this has not yet been rigorously proved for the forces that prevail within animals and plants.

A «field of force» is any region in which a given force has a sensible magnitude. A conductor charged with electricity, for example, exerts an attractive (or repulsive) force upon all bodies that are exterior to it, and, from the point of view of theoretical physics, this force still exists at an infinite distance from the charged body, though at such a distance it becomes infinitesimal in intensity. From a practical standpoint, however, the «field of force» due to the charged body can be considered to be limited by an indefinite but finite boundary, whose distance from the body depends upon the intensity of the charge, and also upon the order of minuteness of the forces that can be regarded as negligible, so far as any effect upon the problem that happens to be under consideration is concerned. Within a closed conductor there is no field of electric force, so long as the charges upon the conductor itself, and in the region external to it, are in equilibrium. This fact may be demonstrated mathematically, and it was also abundantly proved, experimentally, by Faraday. (See ELASTICITY; ELECTRICITY; ETHER; GRAVITATION; MECHANICS; etc.) Consult, also, Mach, 'Principles of Mechanics'; Pearson, 'The Grammar of Science'; Ziwet, 'Elementary Treatise on Theoretical Mechanics.'

Force Bill, a popular name in the United States for four different congressional bills, used at the time of their passage; all aimed at the South, and intended to suppress by national force direct or indirect nullification (q.v.) of national laws. (1) The bill of 2 March 1833 to enforce the tariff law; drawn out by Calhoun's nullification ordinance passed by the South Carolina legislature (See COMPROMISE OF 1833); also called the "Bloody Bill." It was not put in action, because South Carolina first suspended and then repealed the Nullification Ordinance. (2) The bill of 31 May 1870 to put down the forcible resistance which the Southern leaders were preparing to offer to the reconstruction governments. It punished by fine and imprisonment, or both, and gave the Federal courts exclusive cognizance of any interference with the registration, voting, etc., of any one, or going on his premises to intimidate him, or personating him in voting or violating State or Federal election laws, or violating the Civil Rights Bill of 1866. (3) The bill of 20 April 1871 to suppress the Kuklux Klan (q.v.). It gave the Federal courts cognizance of suits against any one depriving another of any constitutional rights; punished as conspiracy any combination to delay the execution of any Federal laws, or deter any one from voting, holding office, or acting as Federal juror or witness; (this clause was held unconstitutional by the Supreme Court); authorized the President to employ the national forces to suppress disorders intended to deprive any class of their constitutional rights, in case the State authorities were unable or unwilling; suspended the habeas corpus "during the continuance of such rebellion" — this provision to remain in force only till the end of the next regular session; authorized the judges to exclude from the juries persons they suspected to be in complicity with the proscribed acts; authorized civil action for damages against all persons who neglected to give warning of such a conspiracy or intended injuries, if they had good reason to suspect them; and confirmed former civil-rights legislation. An attempt was made to extend the fourth suspension of the habeas corpus to May 1872, and the Senate did so, but the House refused. (See RECONSTRUCTION.) (4) The Lodge Election Bill, 2 July 1890, "to amend and supplement the election laws of the United States, and to provide for a more efficient enforcement of such laws." It passed the House, but was tabled in the Senate by a free-coinage fusion of Democrats and Republicans who wished to pass to currency legislation.

Force of Gravity. The determination of the force of gravity from point to point over the earth's surface is a matter of importance. The force of gravity is not the same all over the surface of the earth. It is least at the equator, and it gradually increases as we recede toward the poles. Thus a given mass, if tested by means of a spring-balance of sufficient delicacy, would appear to weigh least at the equator, and would seem to get heavier and heavier as the latitude increases. This is due to two causes: (1) owing to the rotation of the earth on its axis every particle of matter tends to fly off from the surface by centrifugal force. The apparent force of gravity at any place is therefore the force of gravity at that place diminished by the centrifugal force. The centrifugal force at the equator is greater than that in high latitudes, because of the greater radius of the circle described at that place. The second cause is the oblate form of the earth. The earth is not a true sphere, but is flattened at the poles. Hence the distance of any attracted point at the equator from the centre of the mass is greater than that of points situated at or near to the poles; the attraction is, therefore, less at the equator than in high latitudes. Experiments to determine the force of gravity from point to point are made by determining the length of a pendulum, that beats seconds at each place. This being known, the force of gravity is easily calculated. See PENDULUM.

The following table gives the lengths of the seconds pendulum at different places, as determined by various experimenters, and also the force of gravity as deduced from their observations:

THE VALUE OF THE ACCELERATING FORCE OF GRAVITY AT DIFFERENT PLACES.

OBSERVER	PLACE	Latitude	Length of seconds pendulum in inches.	Acceleration of gravity in feet per second.
